The course will be omitted on April 19 because of the holiday

#### HAMPDEN

Thursday, April 20, at 4 00 p m., at the Academy of Medicine, Professional Building, 20 Maple Street, Springfield, and at 8 00 p m., in the Outpatient Department of the Skinner Clinic, Holyoke Hospital, Holyoke. Subject—The Control and Treatment of Respiratory Infections. (This is to include the serological treatment of pneumonia in infants and children) Instructor Charles F McKhann George L. Schadt, *Chairman*

#### MIDDLESEX SOUTH

Tuesday, April 18, at 4 30 p m., at the Cambridge Hospital, 330 Mt. Auburn Street, Cambridge. Subject—Gonorrhea Modern treatment of gonorrhea Instructor Fletcher H Colby Alexander A Levi, *Chairman*

#### SUFFOLK

Thursday, April 20, at 4 30 p m., in John Ware Hall, Boston Medical Library, 8 Fenway, Boston. Subject—Whooping Cough Diagnosis and treatment. Instructor Warren R Sisson Reginald Fitz, *Chairman*

### DEATHS

LITCHFIELD—WILLIAM H. LITCHFIELD, M.D., of Marblehead, died April 2 He was in his eighty fifth year Dr Litchfield received his degree from Harvard Medical School in 1882. He was a member of the Massachusetts Medical Society and the American Medical Association

WALKER—LEWIS M WALKER, M.D., formerly of Cambridge, died in St Augustine, Florida, April 4 He was in his seventy third year

Dr Walker received his degree from Harvard Medical School in 1891 He was a fellow of the Massachusetts Medical Society and the American Medical Association and held memberships in the American Psychiatric Association and the New England Society of Psychiatry

His widow survives him

### INFANTILE ECZEMA\*

Eczema is one of the common ailments of infancy While it may be sometimes caused by fungous infection, similar to that which causes athlete's foot, or by ordinary external irritation of many sorts, by far the commonest cause is

A Green Lights to Health broadcast given by Dr Lewis Webb Hill on Wednesday January 25 and sponsored by the Public Education Committee of the Massachusetts Medical Society and the Massachusetts Department of Public Health

what is called allergic sensitization to foods or, more rarely, to substances in the environment, such as feathers, house dust, wool or various other animal hairs. Different persons are sensitive to different kinds of foods or substances—sometimes to only one or two, sometimes to many. I shall confine my discussion to this type of eczema.

By an allergic person is meant one who has an abnormal sensitivity to substances either in the diet or surroundings, which do no harm to most persons. These substances are called allergens. Allergic sensitization is usually shown by eczema, asthma or hay fever, when the individual is exposed to the allergens to which he is sensitive. It is not well understood why some people react in this abnormal way to things which are harmless for most people. One can say only that they have a certain type of constitution, and that this constitution is often hereditarily transmitted, for it is common to find families in which eczema, asthma or hay fever is unusually prevalent.

Infantile eczema usually starts at about the third or fourth month, on the cheeks, scalp and forehead. It may then spread to other parts of the body, particularly the neck, arms and the outer parts of the lower legs. Sometimes in severe cases the entire skin surface may be affected. Many infants with eczema recover of themselves during the second year, in others the eruption may become chronic, and may last all through childhood, even well into adult life. Many infants who have had eczema later develop asthma or hay fever.

The treatment of infantile eczema is not easy, either for the mother or doctor, and all treatment must be carried out in the most detailed manner. While understanding of this disorder has increased a great deal in the last twenty years, it is in reality a most complicated condition, and there are many aspects of it about which but little is known.

The first step in the investigation of any case of allergic eczema is to determine the allergens to which the infant is sensitive. This is done by making many small scratches on the back, and applying to each scratch, extracts of various foods and environmental allergens to which the infant may have been exposed. Sensitivity to an allergen is indicated by a raised red blotch, something like a large mosquito bite, appearing in about fifteen minutes on the particular scratch to which the allergen in question has been applied. These tests have helped a great deal in the study of the allergic diseases, but they are by no means entirely reliable, for sometimes a patient will fail to give a positive skin test to an allergen to which he is really sensitive, or he may give a positive test to one to which he is not sensitive and which has nothing to do with the cause of his eczema. A positive skin test indicates, therefore, only a possible, not a certain, causative factor.

An eczematous infant is tested with all the foods he is eating, and with a number of the common environmental allergens, such as wool, feathers, house dust and silk. Let us consider for a moment the foods which most infants eat at the age of six months, and their relative importance in the causation of allergic eczema. Most infants at this age are eating cow's milk, wheat cereal, various vegetables, sometimes egg yolk, cod liver oil and orange juice. Positive skin tests are most frequently obtained to egg, milk and wheat. The frequency of positive tests to egg at first glance seems strange, for most of these babies were not eating it when the eczema began, and many of them have never eaten it at any time. Furthermore, the sensitization to egg is usually a very violent one, and many of the egg sensitive babies will be made severely ill if they eat it, and may immediately break out with hives all over the body. There has been much discussion

about why there is this sensitivity to egg in young infants who have never eaten it. The most commonly accepted theory is that they were sensitized to it before they were born by egg eaten by the mother during her pregnancy. So while egg sensitivity is very common in these babies, and may be of high degree, it is not often the cause of the eczema unless the baby is eating egg, which he usually is not.

The situation is very different for milk, as the baby is daily taking large amounts of it. Indeed it has seemed to me that sensitization to cow's milk is the commonest single cause of allergic eczema in infancy. Wheat sensitivity is likewise common, and about doubles in incidence after the fifth or sixth month, when most babies begin to take cereal. Sensitivity to peas or spinach is not uncommon. Positive skin tests to orange are not common, but the mother often notices that the baby begins to itch, or that his skin becomes redder, soon after taking orange juice, so that it may be of more importance than is indicated by the skin tests. Sensitivity to fish oil is not common, but may occasionally exist and, when it does, may be of high degree.

There have been many different diets recommended in the treatment of infantile eczema, which have had a brief period of popularity and have then been discarded. At the present time most of those who have made a study of the subject believe that the discovery of the food or foods to which the infant is sensitized, and removal of these from the diet, is the best method of dietetic treatment now available. Such treatment does not always prove successful, however. Furthermore, it must not be forgotten that many causes of infantile eczema have nothing to do with diet, and may come from outside causes. Mothers and many doctors have been too ready to believe that any and all forms of skin eruption in infants are of food origin, but this is not so.

It must be remembered that the patients we are dealing with have a particular type of constitution. The skin symptoms may often be helped by removal of sensitizing foods from the diet, but the type of constitution is not changed, the patient still has his abnormal capacity for becoming sensitized to other foods or environmental allergens, substances such as dust and feathers, as he becomes older, and may develop asthma or hay fever in childhood, even if his eczema in infancy has been cured by the removal of the special offending foods.

In planning a diet for eczematous children it is necessary to bear in mind that it must be an adequate one, no matter what the skin tests show—the whole child is more important than his skin. There is usually little difficulty, however. There are many cereals and vegetables from which to choose if sensitivity exists to one of the group, and if there is sensitivity to orange or tomato juice, vitamin C in tablets, in the form of cevitamic acid, can easily be substituted. Milk offers the greatest difficulty. In cases with milk sensitivity there are three methods of feeding that may be used.

(1) Evaporated cow's milk may be tolerated. In the process of evaporating milk it is heated very hot, which to a certain extent changes the albuminous portion of the milk, so that it may sometimes be taken by milk sensitive infants when fresh milk cannot. It is the best form of milk to use in infantile eczema if cow's milk is to be used at all, but is in my experience not so efficient in eczema as it sometimes is in other forms of milk sensitivity, and I have not seen many milk sensitive eczematous infants cured by the use of evaporated cow's milk.

(2) Goat's milk is somewhat better, and occasionally brilliant results are secured by its use. The trouble is, however, that many eczematous babies are sensitized to goat's milk as well as to cow's milk, and in these it does no good.

(3) Better results are likely to be obtained by the use of a milk-free food, of which there are several on the market. Most of these are made with soy-bean flour as a base, and many babies will grow and gain weight on these foods as well as they do on milk. These foods have the disadvantage, however, that they sometimes cause loose, very bulky bowel movements and irritated buttocks, and they should not be used for undernourished babies, for in such babies if severe diarrhea results it may be more serious than the original eczema. With these exceptions, such foods may be said to have proved very useful in dealing with milk-sensitive babies.

If the baby is sensitized to environmental allergens, it is necessary to avoid them. Many eczematous babies give positive skin tests to feathers and house dust, although it is by no means always or indeed often possible to prove that such sensitization is the cause of the eczema. It is well, however, to allow no eczematous baby to sleep on a feather pillow, and to keep his room as bare and as free from dust as possible. Wool is another potent source of trouble. Although there may sometimes be allergic sensitization to wool, it has seemed to me that it is more often irritating on account of its natural irritating quality—rubbing on wool will almost always make the eczema worse.

Determination of the allergens to which an infant is sensitized and removal of them are important but only a part of the treatment. Careful nursing and skilled local treatment are of equal importance. In young infants a large proportion of the inflammation that one sees on the skin is caused by scratching and rubbing. It is therefore necessary to restrain them in order to prevent this. The two best methods have been, in my experience, the use of heavy cardboard tubular splints over the elbows, so that they cannot be bent, and the tying of the wrists and ankles to the sides of the crib with soft tape. Itching is very difficult to control, and as a matter of fact I doubt if there is any local application that really stops it. A small amount of carbolic acid added to any lotion or salve that is being used will help somewhat, but often a quieting medicine at night may be necessary to secure sleep. The only really efficient way to control itching is to cure the eczema.

It has been said that no water should be used on the skin of an eczematous baby. This may be so for very acute cases, but it hardly holds true for all cases, and there is usually no objection to washing with water the buttocks, groins or any other parts that are dirty. I am not much in favor of oil baths for acute cases. They sometimes do more harm than good.

There have been innumerable salves and lotions used in the treatment of infantile eczema, and the particular stage in which the eczema happens to be calls for much judgment in selecting an appropriate local application. Furthermore, what is good for one baby may be bad for another. It may be said, however, that tar ointment, prepared with crude coal tar, is often very efficacious, and that simple boracic acid ointment is always safe and sometimes works surprisingly well, particularly if the parts on which it is used can be bandaged and thus kept free from outside irritation. If the eczema is of the weeping oozy type, ointments and thick lotions should not be used. This

stage is best treated by applications of a solution of boracic acid, or by a weak solution of several other substances which your doctor can provide. In not a few cases too strong or unsuitable local remedies make an existing eruption worse, and it is well to be guided by your doctor rather than by well meaning friends or the patent medicine counter.

Finally, most cases of infantile eczema are not cured quickly. To get the better of this disorder involves much time and patience and most careful nursing.

## MISCELLANY

### CHRONIC NONTUBERCULOUS INFECTIONS OF THE LUNG

Bitter experience has taught many a practitioner to keep tuberculosis always in mind. Cough, expectoration, fatigue and other indefinite symptoms rouse in him the suspicion that tuberculosis may be the cause. Such an attitude is good, but it should be balanced by the realization that there are many conditions strongly suggestive of tuberculosis which are nontuberculous. At the thirty-fourth annual meeting of the National Tuberculosis Association there was presented a symposium on "Chronic Nontuberculous Infections of the Lung." Abstracts from one of the papers, based on experiences by Dr. Robert G. Block and Dr. Byron F. Francis (*Am. Rev. Tuberc.* 38: 651-662, 1938) in the Department of Medicine, University of Chicago, are here presented.

Bronchiectasis and abscess are the most important non-specific pulmonary infections, especially from the standpoint of public health. A study of the clinical material accumulated over a period of ten years results in a number of etiologic and clinical observations. Roentgenological examination is a minor aid in recognizing nontuberculous infections of the lung (though necessary in diagnosing their exact distribution and extent) because the anamnesis together with physical examination leads so securely to a diagnosis.

#### BRONCHIECTASIS

Of 200 patients records with the diagnosis "bronchiectasis" admitted to the institution in a ten year period, 140 were rejected for various reasons: that is, bronchiectasis was diagnosed as a minor condition of little significance, it was merely registered as an impression, the bronchiectasis was a development secondary to tuberculosis. The remaining 60 patients include only those in whom moderate or pronounced symptoms of bronchiectasis were the sole reason for the patients having sought medical aid, in whom the presence of the condition was known and in whom a reasonable effort had been made to find extra-pulmonary etiology. Almost all had an advanced degree of bronchial dilatation.

The ages of these 60 cases ranged from ten to sixty-seven, the average age being about twenty-nine years. The estimated average age at the beginning of symptoms was about fourteen years and the average duration of chronic symptoms about fifteen years.

Primary, or predisposing conditions and the secondary or immediate cause, are recognized. The primary condition consists largely of the array of infectious diseases of the upper respiratory tract. Among the secondary causes, involvement of the nasal sinuses, chiefly the maxillary ones, plays the dominant role in the origin of bronchiec-

what is called allergic sensitization to foods or, more rarely, to substances in the environment, such as feathers, house dust, wool or various other animal hairs. Different persons are sensitive to different kinds of foods or substances—sometimes to only one or two, sometimes to many. I shall confine my discussion to this type of eczema.

## CORRESPONDENCE

## CONTROL OF SYPHILIS

*To the Editor* I have been interested in the prevention of contagious and infectious diseases, especially gonorrhea and syphilis, for over twenty five years. I have made a careful study with the purpose of preventing these diseases. This has been done quite successfully in other countries and can be done in this country.

I have had bills introduced into the legislature dealing with the prevention of syphilis and gonorrhea, and since Dr Parran has brought these diseases out into the open, and other states in the union have passed legislation which aims to protect young men and girls at marriage, I have studied the statutes of those states and introduced a bill last year picking out the important parts of the statutes of other states and improving them, in my opinion, to make them more workable. In my last year's bill, I had a section covering a minimum fee for such examinations, with the main purpose in mind to prevent politicians from accusing us of having a racket. There was some objection to it, and I took this section out of my bill this year.

In all those states having premarital legislation, when syphilis is found in one or both parties, the law does not permit the issuance of a license, and this has been a very serious objection from the clergy. My bill eliminates this and does not prevent marriage, providing whichever one of the couple happens to have syphilis is willing to come before a commission of three specialists in venereal diseases, agrees to take an immediate first treatment and takes oath before the other partner that he or she will continue to take the treatment regularly on the appointed time, to be given by some competent, experienced physician in syphilis or at some clinic, as ordered and until discharged by the physician or by the clinic.

I believe that this bill, House Bill 1828, covers the situation as well as can be done at this time without antagonizing the clergy, who are of the opinion that marriages are made in Heaven and should not be interfered with.

The bill is as follows

## HOUSE BILL 1828

## AN ACT REQUIRING CERTIFICATES OF NEGATIVE BLOOD EXAMINATION OF BOTH PARTIES WITH FILING OF MARRIAGE INTENTION

Be it enacted by the Senate and House of Representatives in General Court assembled and by the authority of the same as follows:

Chapter two hundred and seven of the General Laws is hereby amended by inserting after section thirty seven, as appearing in the Tercentenary Edition the following new sections:—

SECTION 37A. The clerk or registrar shall not issue a marriage license unless both parties shall have presented a certificate signed by a regular practitioner of medicine, practicing in the commonwealth showing that a blood examination of both parties has been made within ten days, separately and individually in which a serological complement fixation or flocculation test was made at a regularly approved laboratory registered under the laws of the commonwealth and that both tests have been negative for syphilis, or unless any such party who fails to present said certificate presents a certificate of a practicing physician that such party has been Wassermann last during a period of three years and received not less than forty arsenphenamine injections and not less than fifty heavy metal injections.

SECTION 37B. A test for gonorrhea shall be requested of both applicants for marriage license but this examination shall be voluntary only on the part of the female and may be waived by her if she refuses such an examination.

SECTION 37C. Said certificate shall be considered confidential and is contained in a separate file designated for such purpose.

SECTION 37D. When so ordered in writing by the judge of probate court of the district in which the marriage is to take place, who in his opinion believes that public policy or the physical condition of either one of the parties requires that the intended marriage be celebrated without delay the requirements of sections thirty seven A and thirty seven B shall be waived on the above order of the judge of the probate court. Such order must be placed on file and recorded and the registrar shall issue the marriage license forthwith, but at the earliest opportunity or within ten days following such marriage, blood examination certificates of each party to the marriage, made by a regular practitioner of medicine in the commonwealth must be filed to complete the marriage law requirements.

SECTION 37E. Any party to a marriage who wilfully or deliberately tries to evade the requirements of sections thirty seven A to thirty seven D by having, some one else take the blood examinations for him or her and presents the results as his or her own shall be punished by a fine of one hundred dollars or by imprisonment not to exceed ninety days.

SECTION 37F. Any physician who shall wilfully or deliberately make any false statement in any certificate provided for in section thirty seven A and thirty seven B shall be punished by a fine of one hundred dollars.

SECTION 37G. Any registrar or town clerk who fails to carry out the duties imposed upon him under sections thirty seven A, thirty seven C and thirty seven D shall be punished by a fine of one hundred dollars for each case.

SECTION 37H. That a commission of three physicians specialists in syphilis and venereal diseases be appointed to carry out the duties and regulations of this premarriage law. The decision of this commission on a disputed case shall be final.

(1) This commission shall be appointed by the governor of the commonwealth for terms of one, two and three years respectively at a salary of five hundred dollars and transportation fares per annum. One member to be designated as the chairman and another as secretary. This commission shall meet once weekly and as often as is necessary to act on individual cases.

(2) Vacancies to be filled as they occur each year by the governor of the commonwealth.

The main purpose for the enactment of this law is to discover syphilis at the earliest possible moment, to institute immediate treatment and not to prevent marriages.

At a hearing at the State House on March 28, in talking to Dr Lund, chairman of the Committee on State and National Legislation of the Massachusetts Medical Society, he stated that he was of the opinion that we needed some legislation on syphilis but he felt that in order to have any passed, we should have to have some milder form of a bill. His committee felt that Representative Cutler's bill with some modification would be the proper bill to have introduced to start the ball rolling. Although I could not get myself to agree with him at first, I finally decided not to push my bill too hard, especially so as I learned at the hearing on March 28 that there were many organizations in favor of Representative Cutler's bill, with the changes made in it.

My other bill, House Bill 1827, deals mainly with pregnancy. This requires a prenatal blood examination for all pregnant women. It should be done as a part of a routine examination on the first visit to an obstetrician or the serological test should be made before the end of the third month. Many of our leading obstetricians and general practitioners have a blood test made as a routine examination in all their cases. This should be universal legislation is necessary to make it so.

It is quite generally agreed by our leading specialists that when syphilis is discovered early in pregnancy—the sooner the better, but before the end of the fourth month—the mother can still give birth to a normal baby in over 90 per cent of the cases, and at the same time, the mother is on her way to prevent organic changes in some organs and to rid herself of this dread disease.

This bill with minor changes was favored by Dr Jakmauh, Representative Cutler and Dr Lund. I agreed to the changes. There was no opposition to the enactment of such legislation.

The bill is as follows

## HOUSE BILL 1827

## AN ACT REQUIRING A SEROLOGICAL BLOOD TEST FOR SYPHILIS OF PREGNANT WOMEN PREFERABLY BEFORE THE END OF THIRD MONTH OF GESTATION

Be it enacted by the Senate and House of Representatives in General Court assembled and by the authority of the same as follows:

SECTION 1. Chapter one hundred and fifteen of the public health laws is hereby amended by adding to section one a provision that a serologic blood test for syphilis shall be made of every pregnant woman.

SECTION 2. Every physician attending pregnant women in the state during gestation shall in the case of every woman so attended take or cause to be taken a sample of blood of such woman at the time of first examination and submit such sample to an approved laboratory for a standard serological blood test for syphilis. The term approved laboratory means a laboratory approved for this purpose by the state department of health or in any city by the department of health of the city laboratory—that is Boston health department laboratory. A standard serological blood test for syphilis is one recognized as such by the state department of health or in any city by its health department laboratory.

SECTION 3. In reporting every birth and stillbirth physicians and others permitted to attend pregnancy cases and required to report births and stillbirths shall on and after March first nineteen hundred and thirty nine, state on the birth certificate or stillbirth certificate, as the case may be, whether a blood test for syphilis has been made during such pregnancy upon a specimen of blood taken from the woman who bore the child.

tasis In this series 45 per cent had definite, and 33 per cent indefinite, sinusitis The discovery of a sinus condition is not only of etiologic interest but of great therapeutic importance Sinus involvement cannot be ruled out without a roentgenological examination Treatment of sinusitis cannot be expected to influence existing bronchial dilatations except, perhaps, in the small child, but it is a prerequisite for the attempt to arrest the process

The symptoms found in the group did not conform to current beliefs The general condition was poor in 25 per cent and just fair in the rest Copious expectoration, however, occurred only in about two thirds, and odorous sputum, supposedly an outstanding characteristic of the condition, in less than half Hemoptysis occurred frequently enough to be eliminated as a criterion in the differentiation of bronchiectasis from other pulmonary diseases, especially tuberculosis

One or both lower lobes were involved in 54 cases (90 per cent) Of single lobes, the left lower one was most frequently affected (33 per cent) There is no good explanation to offer for the frequent involvement of the left lower lobe

The therapy of bronchiectasis, until very recently, has been a disappointing chapter Conservative procedures, such as general management, postural drainage, bronchial lavage and bronchoscopic treatment, are palliative and any improvement is merely symptomatic By meticulous care the progressive bronchial dilatation will, at best, be delayed, and the patient remains an easy victim for complicating or intercurrent disease Collapse therapy has, on the whole, proved itself a failure During the past few years very encouraging results have been reported from removal of bronchiectatic lobes Lobectomy, however, requires a unilateral, or practically unilateral, involvement In suitable cases the patient should be urged to submit to operative treatment

The most important of all therapies, prevention, has been sadly neglected up to now There is a good deal of parental negligence toward chronic, upper respiratory infections and moderate chronic bronchitis in children The threat of a severe and permanent bronchial damage is practically unknown People to whom tuberculosis is a household word have not heard of bronchiectasis, although physicians recognize it as, next to neoplasm, the most hopeless pulmonary disease, so far as restitution of the diseased part of the lung is concerned Great concern is felt when a child aspirates a foreign body, considerable attention is paid nowadays to impairments of the respiratory function from allergic causes, but the danger of the slow and continuous drainage of infected material into the bronchial passages and of the resulting bronchitis is underestimated And yet, it is the chief causative factor of bronchiectasis, especially of the extensive and life-threatening variety We should venture to say that in proportion to the growing recognition of the role which chronic sinusitis has in this disease, its occurrence should decrease At present it needs to be looked upon as a public health problem requiring the efforts of agencies concerning themselves with public health By propaganda, examination of the sinuses, including a roentgenogram, should be suggested to the parents and guardians of all children in whom no other cause of a chronic cough can be found The competent treatment of sinus conditions should be suggested

The drier regions of the country offer hope to those who

have, or are threatened with, chronic nonspecific infections of the respiratory tract

#### LUNG ABSCESS

While bronchiectasis is characterized by chronicity of events, lung abscess nearly always begins as an acute involvement Its chronicity occurs from the lung's inability to rid itself promptly of infected material, while the bronchiectatic lesion is largely produced by the very process of chronic elimination It can be estimated that an abscess becomes chronic in somewhat more than one or two months of duration of illness The average duration until death or recovery in this series of cases was slightly over four months Etiologic factors were equally divided between aspiration from extrapulmonary infections and other causes Symptoms depend on the virulence of the invading micro-organisms and the local tissue response but chiefly on the degree of bronchial connection with the abscess and the resulting possibility of spontaneous drainage Physical findings comprise the whole array of pulmonary signs

The primary aim in treatment is to assure adequate drainage of the abscess If this cannot be done promptly, surgical drainage should not be delayed On the other hand, most abscesses which refuse to heal spontaneously become localized quickly and can be operated with greater safety than in the acute stage Postural drainage by using a bed which can be tilted in all directions has been used successfully by the authors The mortality was 50 per cent

Preventive measures should include education of the public and the medical and dental professions to promote dental care, warning against unwarranted and unskillful tonsillectomies and tooth extractions, and preventing upper respiratory infections — Reprinted from *Tuberculosis Abstracts*, March, 1939

#### NOTES

The Educational Committee of the Boston Psychoanalytic Institute has recently announced the choice of Dr Charles Brenner, Dr George E Gardner, and Dr John Romano as recipients of the Sigmund Freud Fellowships for Psychoanalytic Training

At the regular meeting of the Massachusetts Psychiatric Society, held on March 24, it was voted to make Dr Winfred Overholser, superintendent of Saint Elizabeth's Hospital in Washington, District of Columbia, and former commissioner of the Massachusetts Department of Mental Diseases, an honorary member of the society in recognition of his many years of work for the advancement of psychiatry in this commonwealth

The acceptance by Mr Henry Parkman, Jr, corporation counsel to the City of Boston, of the general chairmanship of the Tufts College Medical School Development Program was recently announced by Dr Leonard Carmichael, president of Tufts Mr Parkman's acceptance to this top post, Dr Carmichael said, 'brings into a long range program for better distribution of medical care and facilities to people throughout New England the leadership of a layman distinguished for his vision and civic mindedness in public office and in community endeavors.' As general chairman, Mr Parkman will give direction and counsel to the steps necessary for the development of the New England Medical Center and its program

## CORRESPONDENCE

## CONTROL OF SYPHILIS

*To the Editor* I have been interested in the prevention of contagious and infectious diseases, especially gonorrhea and syphilis, for over twenty five years. I have made a careful study with the purpose of preventing these diseases. This has been done quite successfully in other countries and can be done in this country.

I have had bills introduced into the legislature dealing with the prevention of syphilis and gonorrhea, and since Dr. Parran has brought these diseases out into the open, and other states in the union have passed legislation which aims to protect young men and girls at marriage, I have studied the statutes of those states and introduced a bill last year picking out the important parts of the statutes of other states and improving them, in my opinion, to make them more workable. In my last year's bill, I had a section covering a minimum fee for such examinations, with the main purpose in mind to prevent politicians from accusing us of having a racket. There was some objection to it, and I took this section out of my bill this year.

In all those states having premarital legislation, when syphilis is found in one or both parties, the law does not permit the issuance of a license, and this has been a very serious objection from the clergy. My bill eliminates this and does not prevent marriage, providing whichever one of the couple happens to have syphilis is willing to come before a commission of three specialists in venereal diseases, agrees to take an immediate first treatment and takes oath before the other partner that he or she will continue to take the treatment regularly on the appointed time, to be given by some competent, experienced physician in syphilis or at some clinic, as ordered and until discharged by the physician or by the clinic.

I believe that this bill, House Bill 1828, covers the situation as well as can be done at this time without antagonizing the clergy, who are of the opinion that marriages are made in Heaven and should not be interfered with.

The bill is as follows:

## HOUSE BILL 1828

## AN ACT REQUIRING CERTIFICATES OF NEGATIVE BLOOD EXAMINATION OF BOTH PARTIES WITH FILING OF MARRIAGE INTENTION

Be it enacted by the Senate and House of Representatives in General Court assembled and by the authority of the same as follows:

Chapter two hundred and seven of the General Laws is hereby amended by inserting after section thirty seven as appearing in the Tercentenary Edition the following new sections:—

SECTION 37A. The clerk or registrar shall not issue a marriage license unless both parties shall have presented a certificate signed by a regular practitioner of medicine, practicing in the commonwealth showing that a blood examination of both parties has been made within ten days separately and individually in which a serological complement fixation or flocculation test was made at a regularly approved laboratory registered under the laws of the commonwealth and that both tests have been negative for syphilis, or unless any such party who fails to present said certificate presents a certificate of a practicing physician that such party has been Wassermann fast during a period of three years and received not less than forty arsenicamine injections and not less than fifty heavy metal injections.

SECTION 37B. A test for gonorrhea shall be requested of both applicants for marriage license but this examination shall be voluntary only on the part of the female and may be waived by her if she refuses such an examination.

SECTION 37C. Said certificate shall be considered confidential and impounded in a separate file designated for such purpose.

SECTION 37D. When so ordered in writing by the judge of probate court of the district in which the marriage is to take place who in his opinion believes that public policy or the physical condition of either one of the parties requires that the intended marriage be celebrated without delay the requirements of sections thirty seven A and thirty seven B shall be waived on the above order of the judge of the probate court. Such order must be placed on file and recorded and the registrar shall issue the marriage license forthwith but at the earliest opportunity or within ten days following such marriage, blood examination certificates of each party to the marriage, made by a regular practitioner of medicine in the commonwealth must be filed to complete the marriage law requirements.

SECTION 37E. Any party to a marriage who wilfully or deliberately tries to evade the requirements of sections thirty seven A to thirty seven D by having some one else take the blood examinations for him or her and presents the results as his or her own shall be punished by a fine of one hundred dollars or by imprisonment not to exceed ninety days.

SECTION 37F. Any physician who shall wilfully or deliberately make any false statement in any certificate provided for in section thirty seven A and thirty seven B shall be punished by a fine of one hundred dollars.

SECTION 37G. Any registrar or town clerk who fails to carry out the duties imposed upon him under sections thirty seven A, thirty seven C and thirty seven D shall be punished by a fine of one hundred dollars for each case.

SECTION 37H. That a commission of three physicians specialists in syphilis and venereal diseases be appointed to carry out the duties and regulations of this pre marriage law. The decision of this commission on a disputed case shall be final.

(1) This commission shall be appointed by the governor of the commonwealth for terms of one two and three years respectively at a salary of five hundred dollars and transportation fares per annum. One member to be designated as the chairman and another as secretary. This commission shall meet once weekly and as often as is necessary to act on individual cases.

(2) Vacancies to be filled as they occur each year by the governor of the commonwealth.

The main purpose for the enactment of this law is to discover syphilis at the earliest possible moment to institute immediate treatment and not to prevent marriages.

At a hearing at the State House on March 28, in talking to Dr. Lund, chairman of the Committee on State and National Legislation of the Massachusetts Medical Society, he stated that he was of the opinion that we needed some legislation on syphilis but he felt that in order to have any passed, we should have to have some milder form of a bill. His committee felt that Representative Cutler's bill with some modification would be the proper bill to have introduced to start the ball-rolling. Although I could not get myself to agree with him at first, I finally decided not to push my bill too hard, especially so as I learned at the hearing on March 28 that there were many organizations in favor of Representative Cutler's bill, with the changes made in it.

My other bill, House Bill 1827, deals mainly with pregnancy. This requires a prenatal blood examination for all pregnant women. It should be done as a part of a routine examination on the first visit to an obstetrician or the serological test should be made before the end of the third month. Many of our leading obstetricians and general practitioners have a blood test made as a routine examination in all their cases. This should be universal. Legislation is necessary to make it so.

It is quite generally agreed by our leading specialists that when syphilis is discovered early in pregnancy—the sooner the better, but before the end of the fourth month—the mother can still give birth to a normal baby in over 90 per cent of the cases, and at the same time, the mother is on her way to prevent organic changes in some organs and to rid herself of this dread disease.

This bill with minor changes was favored by Dr. Jakmauh, Representative Cutler and Dr. Lund. I agreed to the changes. There was no opposition to the enactment of such legislation.

The bill is as follows:

## HOUSE BILL 1827

## AN ACT REQUIRING A SEROLOGICAL BLOOD TEST FOR SYPHILIS OF PREGNANT WOMEN PREFERABLY BEFORE THE END OF THIRD MONTH OF GESTATION

Be it enacted by the Senate and House of Representatives in General Court assembled and by the authority of the same as follows:

SECTION 1. Chapter one hundred and fifteen of the public health laws is hereby amended by adding to section one a provision that a serologic blood test for syphilis shall be made of every pregnant woman.

SECTION 2. Every physician attending pregnant women in the state during gestation shall in the case of every woman so attended take or cause to be taken a sample of blood of such woman at the time of first examination and submit such sample to an approved laboratory for a standard serological blood test for syphilis. The term approved laboratory means a laboratory approved for this purpose by the state department of health or in any city by the department of health of the city laboratory—that is Boston health department laboratory. A standard serological blood test for syphilis is one recognized as such by the state department of health or in any city by its health department laboratory.

SECTION 3. In reporting every birth and stillbirth physicians and others permitted to attend pregnancy cases and required to report births and stillbirths shall on and after March first nineteen hundred and thirty nine state on the birth certificate or stillbirth certificate as the case may be, whether a blood test for syphilis has been made during such pregnancy upon a specimen of blood taken from the woman who bore the child.

for which a birth or stillbirth certificate is filed. If such test has been made during pregnancy those required to report births and stillbirths shall state the date on which the test was made. In addition to the information provided to be contained in each certificate of birth or such similar certificate of birth required in the state of Massachusetts every certificate of birth shall state whether such test was made during pregnancy or at delivery and in the case where no blood test has been made such fact shall be reported together with the reason why such test has not been taken in compliance with the provisions of section two of this chapter. In no event shall the birth certificate state the result of the test.

Section 4 The sum of one thousand dollars or so much thereof as may be necessary is hereby appropriated out of any moneys in the state treasury to the state department of health to cover additional clerical printing and other expenses in carrying out the provisions of this act.

Section 5 This act shall take effect immediately.

Sections 3, 4 and 5 will be eliminated with perhaps slight changes in the wording of Section 2. Three states now have prenatal legislation, New York among them. It is working out successfully.

My bills have been overlooked by our legislative committee and have not been mentioned.

The State Printing Office was somewhat delayed in publishing many of the bills which came after 1000. I feel that this was just an oversight as the other bills have been published in the *Journal*.

There are now fifteen states out of twenty six which have definite prenuptial statutes. There are other states which are considering such laws. Massachusetts has always been a leader in progressive legislation, and it is rather unfortunate that we have lagged behind in such a most worthy cause. It has been definitely proved by other countries that syphilis can be controlled and prevented.

Statistics show that about 40 per cent of new cases are innocently contracted. If this is so, or even near so, something should be done to stop the suffering and tragedy that syphilis causes. Since we have specific methods of treatment, the medical profession owes it to itself and to the traditions for which it stands to take immediate action and not lag behind in such a serious situation. When we compare our figures of annual incidence with those of Norway, Sweden, Denmark, Switzerland and England, especially the first three countries, we are actually put to shame.

It is a duty that each one of us owes to ourself and to the community to take an active interest in this crusade against Public Enemy Number One—Syphilis.

*Delenda est syphilis!*

H. M. LANDESMAN, M.D.

366 Commonwealth Avenue,  
Boston

\* \* \*

Dr. Landesman's letter was referred to Dr. Charles C. Lund, chairman of the Committee on State and National Legislation of the Massachusetts Medical Society, who comments as follows:

To the Editor: Dr. Landesman's two bills were given very careful consideration by the Committee on State and National Legislation of the Massachusetts Medical Society. It was believed that House Bill 1828 was altogether too complicated and that it called only for a blood test and not for a medical examination.

We have agreed to back House Bill 1827 provided the phrase beginning on line 9 of Section 2, "or in any city by the department of health of the city laboratory, that is, Boston Health Department Laboratory," and the phrase in line 13, of Section 2, "or in any city by its health department laboratory," are deleted and provided further that Sections 3, 4 and 5 are deleted.

CHARLES C. LUND, M.D.

## NOTICES

### REMOVALS

BENJAMIN F. BORNSTEIN, M.D., announces the removal of his office to The Eliot, 370 Commonwealth Avenue, Boston. Telephone KENmore 1720.

JOHN T. HARISSIS, M.D., announces the removal of his office to 307 Harvard Street, Cambridge, Massachusetts. Telephone KIRkland 5138.

### CARNEY HOSPITAL

The monthly clinical meeting and luncheon of the Carney Hospital will be held in the Andrew Carney Assembly Hall on Monday, April 17, at 11 30 a.m.

#### PROGRAM

##### Case Reports

Common Eye Injuries. Dr. E. F. Eagan. Discussion by Dr. James J. Regan, Dr. H. Boruchoff and Dr. A. J. Cregg.

Physicians and medical students are cordially invited to attend.

ROY J. HEFFERNAN, M.D., *Secretary*

### BOSTON LYING IN HOSPITAL

The next Journal Club meeting will be held on Wednesday evening, April 19, at 8 30 p.m., at the Boston Lying-in Hospital.

Dr. William E. Studdiford, professor of obstetrics and gynecology at New York University, will speak on "The Treatment of Abortion." Discussion will be conducted by Drs. Arthur T. Hertig and John T. Williams.

Physicians and students are cordially invited to attend.

DUNCAN E. REID, M.D., *Secretary*

### BOSTON MEDICAL HISTORY CLUB

The Boston Medical History Club will meet at the Boston Medical Library, 8 Fenway, Boston, on Monday evening, April 17, at 8 15 p.m. Dr. Elliott C. Cutler will speak on "The Darkest Days of Surgery."

Members of the medical profession and other interested persons are cordially invited to attend this meeting.

PAUL D. WHITE, M.D., *President*,  
BENJAMIN SPECTOR, M.D., *Secretary*

### BOSTON DOCTORS SYMPHONY ORCHESTRA

*Nicola Slonimsky*

Rehearsals of the newly organized Boston Doctors Symphony Orchestra, conducted by Nicola Slonimsky, are held every Thursday evening at 7 30 at Hampton Court Hotel, 1223 Beacon Street, Brookline.

Membership is still open. All physicians, dentists and medical and dental students who are interested should communicate with Dr. Julius Loman, Pelham Hall Hotel, Brookline (BEA 2430).

### MEDICAL CLINIC AT THE PETER BENT BRIGHAM HOSPITAL

At 3 30 p m. on Thursday, April 20, in the amphitheater of the Peter Bent Brigham Hospital, Dr Henry A. Christian will give a medical clinic. Practitioners and medical students are cordially invited to attend.

### HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held on Tuesday, April 25, at 8 15 p m., in the amphitheater of the Peter Bent Brigham Hospital (Shattuck Street entrance)

Dr Francis G Blake, Sterling Professor of Medicine, Yale University, New Haven, Connecticut, will speak on 'The Clinical Use of Sulfapyridine in Coccal Infections'. Discussion by Dr Lewellys F Barker, Baltimore, Dr A. H. Gordon, Montreal, Dr Duncan Graham, Toronto, Dr W T Longcope, Baltimore, Dr O H P Pepper, Philadelphia, Dr David Riesman, Philadelphia, and Dr R T Woodyatt, Chicago. Dr Henry A. Christian will preside.

Medical students and physicians are cordially invited to attend.

ROBERT M ZOLLINGER, M.D., *Secretary*

### CAMBRIDGE HOSPITAL

The regular clinicopathological meeting of the staff of the Cambridge Hospital will be held at the hospital in the Margaret Jewett Hall, 330 Mt. Auburn Street, Cambridge, on Tuesday, April 18, at 8.30 p m.

All members of the medical staff are cordially invited to attend.

STEPHEN M. BIDDLE, M.D., *Secretary*

### THE FRANCIS AMORY SEPTENNIAL PRIZE OF THE AMERICAN ACADEMY OF ARTS AND SCIENCES

In compliance with the requirements of a gift under the will of the late Francis Amory, of Beverly, Massachusetts, the American Academy of Arts and Sciences announces the offer of a septennial prize for outstanding work with reference to the alleviation or cure of diseases affecting the human genital organs, to be known as the Francis Amory Septennial Prize. The gift provides a fund, the income of which may be awarded for conspicuously meritorious contributions to the field of knowledge during the said septennial period next preceding any award thereof, through experiment, study or otherwise in the diseases of the human sexual generative organs in general. The prize may be awarded to any individual or individuals for work of "extraordinary or exceptional merit in this field.

In case there is work of a quality to warrant it, the first award will be made in 1940. The total amount of the award will exceed ten thousand dollars, and may be given in one or more awards. It rests solely within the discretion of the Academy whether an award shall be made at the end of any given seven-year period, and also whether on any occasion the prize shall be awarded to more than a single individual.

While there will be no formal nominations, and no formal essays or treatises will be required, the committee invites suggestions, which should be made to the Amory Fund Committee, care of the American Academy of Arts and Sciences, 28 Newbury Street, Boston.

### ESSEX SOUTH DISTRICT MEDICAL SOCIETY

The annual meeting of the Essex South District Medical Society will be held at the Salem Country Club, Peabody, on Wednesday, May 10. Dr Peer P Johnson will speak on "A Trip to the Virgin Islands."

J ROBERT SHAUGHNESSY, M.D., *Secretary*

### NEW ENGLAND ROENTGEN RAY SOCIETY

The next meeting of the New England Roentgen Ray Society will be held on April 21, at 8 15 p m., in the Sise Auditorium of the Lahey Clinic, 605 Commonwealth Avenue, Boston.

#### PROGRAM

Pneumospinograms for Demonstrating Herniated Disks. Dr J L Poppen.

The Lumbosacral Joint. Dr G E. Haggart.

Observations on the Heart in Hyperthyroidism. Dr L. M. Hurvthal.

Unusual Chest Tumors. Dr H. D. Adams.

Unusual Lesions of the Stomach. Dr S F Marshall.

Lesions of the Small Bowel. Dr E. D. Kiefer.

The Diagnosis of Lesions of the Colon. Dr R. B. Cattell.

Carcinoma of the Cervix Uteri. Dr H. F. Hare.

Carcinoma of the Thyroid. Dr F. H. Lahey.

Dinner at the Harvard Club will be served at 6.30 p m.

EDWARD C. VOGT, M.D., *President*,  
AUBREY O. HAMPTON, M.D., *Secretary*

### NEW ENGLAND HEART ASSOCIATION

The next meeting of the New England Heart Association will be held on Friday, April 28.

#### PROGRAM

4 00 p m. Regular meeting at the House of the Good Samaritan.

6 30 p m. Annual dinner at the Harvard Club.

8 15 p m. Annual meeting and Henry Jackson Lecture at the Boston Medical Library, 8 Fenway, Boston. Dr Harry Goldblatt, associate director, Institute of Pathology, Western Reserve University, will speak on 'Experimental Observations on the Pathogenesis and Treatment of Hypertension.'

Interested physicians and medical students are invited to attend the meetings.

EDWARD F. BLAND, M.D., *Secretary*

### NEW ENGLAND SOCIETY OF PHYSICAL MEDICINE

Because of the holiday the regular meeting of the New England Society of Physical Medicine scheduled for April 19 will be postponed to Wednesday evening, April 26, at the Hotel Kenmore, Boston.

WILLIAM D. McFEE, M.D., *Secretary*

## NEW ENGLAND PATHOLOGICAL SOCIETY

The next meeting of the New England Pathological Society will be held at the Wrentham State School, Wrentham, on Thursday, April 20, at 8 00 p m

## PROGRAM

The Bone Development in Mongoloid Deficiency Dr Clemens E Benda, Wrentham

Epidermoid Cysts Dr Thomas G Cogswell, Worcester

Nervous System Lesions in Hyperinsulinism Dr H M Zimmerman, New Haven, Connecticut

Arteriosclerosis Dr Milton C Winternitz, New Haven, Connecticut

GRANVILLE A BENNETT, M.D., Secretary

## BOOK REVIEW

*The Scientist in Action A scientific study of his methods*  
William H. George. 354 pp New York Emerson Books, Inc., 1938 \$3 00

It may be said that this book will provoke considerable reaction, agreeable as well as disagreeable, on the part of scientists, social workers, psychologists and philosophers. Mr George formulates succinctly the thesis that "man, whether he be infant, idiot or intellectual, from crèche almost to crematorium is seen as perpetually patterning, that speaking, writing or manipulation of apparatus in a laboratory are forms of action, but thinking, believing or feeling are not. This book should be read under the best of conditions, both physical and mental, in order that one may critically challenge the emphasis which the author makes on the possibility that in science there resides an instrument for achieving a happier social order. In view of the recent attitude taken by representatives of the American Association for the Advancement of Science and the comparable association in Great Britain, a challenge to this thesis is properly in order. Inasmuch as this review is not of the essay type, it may be pointed out that anyone interested in the thought and content of science should not only read this book but should own it and frequently take it off the shelf for reconsideration

## MALIGNANT MELANOMAS\*

### A Clinical Study

ERNEST M DALAND, M.D.,† AND JOSEPH A HOLMES, M.D.‡

BOSTON

OUR interest in malignant melanomas has been stimulated by the extreme pessimism expressed toward the disease by many members of the medical profession. Malignant melanomas have been recognized as probably the most highly malignant of all tumors, and we are aware of many cases in which a hopeless prognosis has been given, and for this reason no treatment advised. Furthermore, many physicians still believe that intervention of any sort will result in widespread metastases. We have been eager to learn through a clinical study of a series of cases whether surgical measures have been effective. Records totaling 174 have been reviewed. Of these, 74 were from the Pondville Hospital, 88 from the Massachusetts General Hospital, 3 from the Cancer Section of the Westfield Sanatorium, and 9 were those of private cases.

We are using the term "malignant melanoma," as recommended by Masson,<sup>1</sup> to represent the tumors variously called melanotic sarcomas, melanosarcomas or melanocarcinomas. Masson has shown that these pigment cells are ectodermal in origin and arise from cells derived from the neural crest. While the lesions are most frequently associated with the skin, they may arise in any part of the body, as cases of primary lesions occurring in practically all structures have been reported.<sup>2-7</sup> Those in the skin usually contain a blue-black or intense black pigment which enables one to make a clinical diagnosis. There are many variations in the pigmentation, and some cells contain no pigment at all. The few cases of amelanotic malignant melanomas showed no difference in course or results from those with pigment. Lesions may be flat or raised above the skin surface and are rarely pedunculated.

No marked difference was noted in the sex incidence, as there were 79 men and 95 women in our series. Cases were found in patients of extremely diverse ages, the youngest being seven and the oldest eighty-eight, the greatest incidence was in the age group from sixty to sixty-nine (Table 1).

TABLE 1 Age Incidence

AGE	NO OF CASES
1-9	1
10-19	4
20-29	14
30-39	15
40-49	34
50-59	32
60-69	46
70-79	24
80-89	4
Total	174

Occupation was not a factor, either in the incidence or in the course of the disease.

The distribution of the lesions was of interest (Table 2). Eighty per cent of the tumors occurred

TABLE 2. Distribution of Lesions

DISTRIBUTION	NO OF CASES	PER CENT
Lower extremity	55	31.6
Upper extremity	11	6.4
Eye	25	14.4
Face and neck	41	23.5
Trunk	28	16.1
Groin and axilla (probable lymph node)	4	2.3
Meninges	3	1.7
Anus	3	1.7
Salivary glands	2	1.1
Vulva	1	0.6
Scalp	1	0.6

on the surface of the body, where they were readily visualized. In nearly a third of our cases they were found on the lower extremities. We wish to stress the high incidence of malignant melanomas on the feet and legs. Those in the Pondville Hospital group represented 55 per cent of all the malignant tumors on the skin of the lower extremities.

Read at the annual meeting of the New England Surgical Society, Boston, October 1, 1938.

\*From the Pondville Hospital and the Westfield Sanatorium, Cancer Section (Massachusetts Department of Public Health) and the Tumor Clinic of the Massachusetts General Hospital.

†Instructor in surgery, Harvard Medical School; chief of staff, Pondville Hospital; assistant visiting surgeon, Massachusetts General Hospital.

‡Formerly surgical resident, Pondville Hospital.

and 35 per cent of all tumors, benign and malignant, in this location

There were 25 cases where the primary focus was in the uveal tract of the eye. Only 3 of these tumors were seen as primary lesions. In many of the secondary cases at the Massachusetts General Hospital the patients had received primary treatment at the Massachusetts Eye and Ear Infirmary, and came to our clinic only after metastatic disease had appeared. For this reason it is quite possible that we do not have as high a percentage of eye cases in our series as would normally be found in the community.

Frequent sites for this condition were the face, neck and trunk. On the trunk, the majority appeared in the region of the scapula. We have no explanation of this fact, and mention it only to emphasize the importance of considering malignancy in tumors in this area. Adair,<sup>8</sup> in his study of 400 cases, states that as a rule the lesion is congenital, but in a few cases there was no previous lesion until a short time before the appearance of the malignant melanoma. Our series has failed to confirm this statement, for in only 18 per cent of the records in which accurate data were found was there a history of a birthmark. Furthermore, 33 per cent of the patients had had a lesion for less than one year (Table 3). A his-

TABLE 3 *Duration of Lesions*

DURATION	NO OF CASES	PERCENTAGE OF KNOWN CASES
Present at birth	24	18.8
Less than 1 year	42	32.8
1-3 years	29	22.6
3-5 years	8	6.3
5 years or over	25	19.5
	128	
Unknown	46	
Total	174	

tory of a recent change in a lesion of considerable duration was noted in 54 cases and was considered of diagnostic importance. No instance of malignant change in a hairy mole was noted in this series. We have seen such an occurrence in one patient very recently.

Trauma has frequently been mentioned as an exciting factor in the stimulation of dormant lesions. Our investigation substantiates this in many cases (Table 4). In this disease on the foot, 8 patients gave a definite history of irritation by a nail or a tight shoe, we believe that it may be a factor in all the foot lesions. Nine patients gave a history of having had desiccation or treatment with caustics followed by an immediate proliferation of the growth. Wherever there is a possibility of a mole's being a benign or malignant

melanoma, Ewing<sup>9</sup> states that it seems advisable not to use electrodesiccation or a local cauterizing agent. Amadon<sup>10</sup> reports 27 cases treated with electrocoagulation, with 100 per cent recurrence. Biopsy, too, is a dangerous procedure, and total removal should be practiced in a suspicious lesion if one is seeking a pathological diagnosis. In 24

cases rapid growth followed injury by incision, a direct blow or fall. One case illustrates this well. A patient experienced a chip fracture of a cervical vertebra by a fall. Two years later she developed neurological symptoms, and operation revealed a malignant melanoma involving the dura and cord at the site of fracture.

We have found that it is not necessary to have

FIGURE 1 *Lymphatic Drainage of the Skin of the Face*

a pre-existing benign lesion or birthmark for the origin of a malignant melanoma. Many of these tumors in our series were apparently malignant from the onset. Inasmuch as pigmented moles are exceedingly common and many must be subjected to irritation, it follows that a comparatively small percentage of them ever develop into malignant tumors. When changes do occur in a mole of some duration, they may assume various characteristics. Those that have been most frequently

brought to our attention are an increase in size, an increase or decrease in pigmentation, and ulceration and bleeding. A few patients have described a sudden elevation followed by a central necrosis. These changes may occur throughout the lesion or in only a part of it (Case 25).

Once the tumors have assumed a malignant character, they may at any time produce widespread metastases. They may grow by direct extension, although this is unusual. Metastatic foci

With the above facts in mind, we have attempted to determine the ideal method of treatment. There is no surgical method of combating blood-stream metastases, and if these have occurred before treatment, cure is impossible. The first step in adequate treatment is wide excision of the local lesion, care being taken not to traumatize the tumor, and to discard any instruments coming in contact with it during removal. A wide margin of apparently normal skin is important, and the

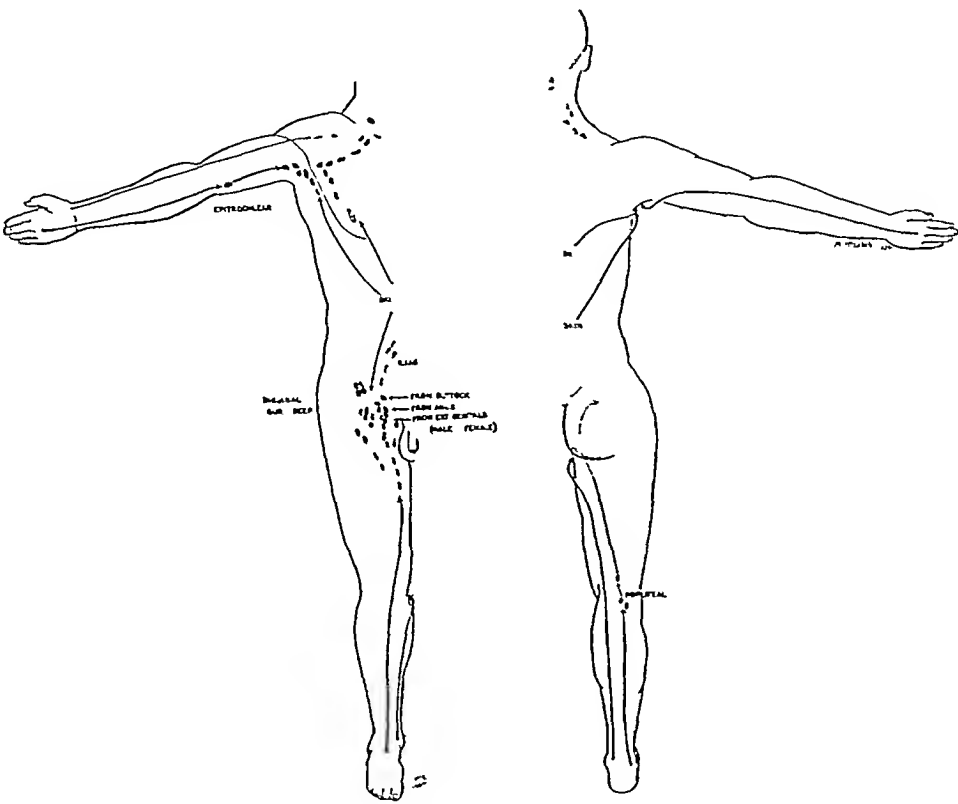

FIGURE 2 Lymphatic Drainage of the Trunk and Extremities

in the skin may occur locally or in close proximity to the primary focus, or may follow the main trunks in the skin lymphatics. By the latter route tumor cells may reach the regional nodes, or they may avoid the skin and travel solely through the deep lymphatic system to the same regional nodes. A third method of dissemination is by way of the blood stream, which may produce metastatic foci in the liver, lungs, brain, bones or skin distant from the primary lesion. This may be a primary or secondary phenomenon, that is from the primary tumor or from the regional nodes which have received tumor cells from the lymphatic system. There is no known way of predicting by which route or routes a given tumor will metastasize.

tumor should be removed without regard to primary closure. The second procedure should be the thorough removal of the regional lymph nodes, these drainage areas are illustrated in Figures 1 and 2. Such dissections are major procedures, yet if they are performed properly and at the right time, the operative complications are slight. We do not subscribe to the doctrine that regional dissection should be deferred until stray tumor cells in the lymphatics have had time to migrate to the nodes. Therefore, if there is no ulceration or infection in the primary lesion, regional dissection may be performed at the time of the removal of the local tumor. If there is a possibility of infection, the regional dissection should be deferred for at least

and 35 per cent of all tumors, benign and malignant, in this location

There were 25 cases where the primary focus was in the uveal tract of the eye. Only 3 of these tumors were seen as primary lesions. In many of the secondary cases at the Massachusetts General Hospital the patients had received primary treatment at the Massachusetts Eye and Ear Infirmary, and came to our clinic only after metastatic disease had appeared. For this reason it is quite possible that we do not have as high a percentage of eye cases in our series as would normally be found in the community.

Frequent sites for this condition were the face, neck and trunk. On the trunk, the majority appeared in the region of the scapula. We have no explanation of this fact, and mention it only to emphasize the importance of considering malignancy in tumors in this area. Adair,<sup>8</sup> in his study of 400 cases, states that as a rule the lesion is congenital, but in a few cases there was no previous lesion until a short time before the appearance of the malignant melanoma. Our series has failed to confirm this statement, for in only 18 per cent of the records in which accurate data were found was there a history of a birthmark. Furthermore, 33 per cent of the patients had had a lesion for less than one year (Table 3). A his-

tory of a recent change in a lesion of considerable duration was noted in 54 cases and was considered of diagnostic importance. No instance of malignant change in a hairy mole was noted in this series. We have seen such an occurrence in one patient very recently.

Trauma has frequently been mentioned as an exciting factor in the stimulation of dormant lesions. Our investigation substantiates this in many cases (Table 4). In this disease on the foot, 8 patients gave a definite history of irritation by a nail or a tight shoe, we believe that it may be a factor in all the foot lesions. Nine patients gave a history of having had desiccation or treatment with caustics followed by an immediate proliferation of the growth. Wherever there is a possibility of a mole's being a benign or malignant

melanoma, Ewing<sup>9</sup> states that it seems advisable not to use electrodesiccation or a local cauterizing agent. Amadon<sup>10</sup> reports 27 cases treated with electrocoagulation, with 100 per cent recurrence. Biopsy, too, is a dangerous procedure, and total removal should be practiced in a suspicious lesion if one is seeking a pathological diagnosis. In 24

in the skin may occur locally or in close proximity to the primary focus, or may follow the main trunks in the skin lymphatics. By the latter route tumor cells may reach the regional nodes, or they may avoid the skin and travel solely through the deep lymphatic system to the same regional nodes. A third method of dissemination is by way of the blood stream, which may produce metastatic foci in the liver, lungs, brain, bones or skin distant from the primary lesion. This may be a primary or secondary phenomenon, that is from the primary tumor or from the regional nodes which have received tumor cells from the lymphatic system. There is no known way of predicting by which route or routes a given tumor will metastasize.

tumor should be removed without regard to primary closure.

The second procedure should be the thorough removal of the regional lymph nodes, these drainage areas are illustrated in Figures 1 and 2. Such dissections are major procedures, yet if they are performed properly and at the right time, the operative complications are slight. We do not subscribe to the doctrine that regional dissection should be deferred until stray tumor cells in the lymphatics have had time to migrate to the nodes. Therefore, if there is no ulceration or infection in the primary lesion, regional dissection may be performed at the time of the removal of the local tumor. If there is a possibility of infection, the regional dissection should be deferred for at least

two weeks or until the possibility of infection in the drainage area is past. By removal of the regional nodes the lymphatic routes have been cut off. This means that if there is to be a recurrence through lymphatic spread it will occur in the region between the primary site and the scar of the regional dissection. In this way the mutilating procedure of complete removal of skin lymphatics, which would be the ideal surgical treatment, is avoided. The lymphatics between the primary site and the regional drainage area may be removed when indicated by recurrent disease. This involves removal of the skin, subcutaneous tissue and superficial fascia down to the muscles (Case 7).

We realize that the treatment outlined above cannot be carried out in all cases. In many of our aged patients such an amount of surgery would not be tolerated, and the life expectancy would not justify anything more than an adequate local excision. The location of the lesion is another factor which hinders regional dissection. Malignant melanomas located directly above the sternum (Case 18) drain primarily to the nodes of the mediastinum and to those on both sides of the neck. Removal of the cervical nodes without the mediastinal nodes is ineffective.

As malignant melanomas of the extremities are the most suitable ones for excision and regional dissection, and as they represent over a third of the cases in our series, their records were closely analyzed in order to determine the efficacy of the proposed program. For lesions on the arm to be considered as having had an adequate regional dissection, an axillary one was required, for those on the leg, an inguinal and saphenous dissection from the lowest angle of Scarpa's triangle was necessary. Many of the cases with lesions on the extremities had local excision only, and although this group is small, it offers some comparison with those receiving the full treatment outlined above. Seventeen patients had local excision only, and 8 of these were dead within three years. Three cases were too recent to evaluate, and in 3 the patients were alive and free of disease two and a half, four and six years, respectively, after excision. Three records had no follow-up notes.

The cases that had the benefit of both local excision and regional dissection were divided into two groups: those with negative regional nodes and those with metastatic disease. In the latter group there were 24 cases. Seven of these patients are living, 3 of these have been operated on too recently to be considered as cures, 3 patients are living five years after treatment, and 1 who has recently had recurrent nodules removed from the scar of the saphenous dissection is alive two and

a half years after primary treatment. Sixteen of the patients who died succumbed to distant or widespread metastases within two years. One patient lived for eleven years, only to die of probable brain metastases. Of the 13 patients who had no disease in the regional nodes, 5 were dead of recurrent disease within two years. There are 4 five-year cures, and 1 patient is free of disease after two years. Two patients were untraced.

In the group of cases which were considered operable when first seen, 16 patients died of distant metastases within a year after treatment. X-ray films of the chest, spine and pelvis were taken in most cases, and chest plates were taken routinely before operation. An exact note regarding the presence or absence of the liver edge was usually found, and although the data on melanuria were incomplete, the absence of melanin did not rule out distant metastatic disease.

Eleven patients with lesions on the extremities had either inoperable regional metastases or extensive distant lesions. All were dead within two years after treatment excepting 1 (Case 35) who showed spontaneous regression of the regional metastatic disease but died six years later of brain metastases. Three cases were lost, and 1 was not included in the group as the original saphenous dissection was not considered adequate.

There were 25 malignant melanomas of the orbit in our series. All but 3 of these were secondary cases, appearing in our clinics with metastatic lesions. In the 3 primary cases the patients are alive without disease nine and a half, six and two years, respectively, after treatment. None of the patients with secondary lesions survived.

Apparently a simple enucleation of the eye is adequate local treatment, for in only 2 cases was there a recurrence in the orbit. It is important to note that in but 1 case did we find direct metastases to the cervical nodes from a malignant melanoma in the uveal tract. There were 2 cases with widespread skin metastases where it was believed that secondary deposits from the skin tumors appeared in the regional nodes of the neck, axilla and inguinal region. Apparently no regional dissection is needed in malignant melanomas of this region.

There is indeed reason for the existing pessimism as to the permanent cure of malignant melanoma of the orbit. As explained previously, we did not have enough primary cases to enable us to draw any conclusions as to the number of cures during this period, for the patients were treated in eye clinics. We were impressed, however, by the number of patients returning with late metastases (Table 5). That tumors of this type metastasize later than any other type is common

knowledge We have known of metastatic foci appearing eighteen and twenty-five years, respectively, after operation

In this series there were late metastases to the liver in 10 cases, to the lungs in 9, to the brain in 3, to the bone in 2 and to the skin or subcutaneous tissues in 4

Forty-one patients had lesions on some part of the face or neck. These patients fall into the group where local excision and regional dissection may be performed. However, we find that neck

dissection was carried out in only 8 cases. Six patients had an adequate local excision, with positive nodes found on dissection of the neck. One is untraced, 3 died in six months, fourteen months and two years, respectively, and 1 case is recent. Two patients had the same operative procedure, but no disease was found in the nodes. These are comparatively recent cases, but both patients are free from disease, one for fourteen months and the other for seven. One patient had a secondary neck dissection but succumbed in four months.

Local excision alone was done in 17 cases. Three of these patients are untraced and 1 was well for ten years and then developed a recurrence in the neck. There are 5 patients living without disease, and 4 have died without recurrence, but none in either group has or had survived five years. Four patients died of early recurrence.

Five patients received x-ray treatment without benefit, and in 6 cases the disease was too far advanced for any treatment.

There are 2 five-year cures in this group of face and neck cases. Furthermore, only 7 patients have lived three years or more after receiving treatment. Malignant melanoma of the face and neck is obviously a serious condition and the prognosis is very poor.

For lesions on the trunk, as elsewhere, the ideal treatment includes a regional dissection, but only 6 patients received such therapy. The results here were poor, 2 postoperative deaths, 3 deaths within a year and 1 case untraced. There were 3 five-year

cures by local excision alone. From the results in this small series there is little to be learned, but the probability is that a few of the patients who died of recurrent disease might have been saved if they had had the benefit of a regional dissection at the time of the primary treatment.

There were 12 cases of bone metastases from this type of tumor. The spine was involved in 3 cases, the skull in 2, the femur in 2, the ilium in 2 and multiple bones in 3. Plevess,<sup>11</sup> in a report of 97 cases from the Toronto General Hospital, found bone metastases in only 2 cases. Geschichter and Copeland<sup>12</sup> demonstrated bone metastases in only 3 of 169 cases. While the incidence of bone metastases is relatively low, even with our incomplete data, 12 cases were found in 174 cases studied.

The results of roentgen therapy were extremely poor. Twenty-two cases received sufficient therapy to determine their sensitivity. Of these, 2 patients (Cases 33 and 34) responded to treatment. One patient who received therapy to metastatic nodes showed good response but died in eight months of cerebral metastases. The other showed complete disappearance of a large mass in the groin and at least regression of lung metastases and was free of all symptoms two and a half years later. These results as a whole are in contrast to such reports as are found in the literature.<sup>13</sup>

The results of treatment are not very encouraging. Of the 90 patients who came to the hospital for primary treatment 50 are dead. There were only 13 five-year cures and in only 3 of these cases were there positive regional metastases. Of these 90 primary cases 21 were treated within the last five years. Six received palliative irradiation and 2 were untreated. This leaves 61 cases in which cure was attempted more than five years ago and 10 untraced. The percentage of cures in the primary group is 21.

The secondary cases include those in which local excision, cauterization, electrodesiccation or incision was done before entry, and those patients who had received adequate primary treatment elsewhere and were admitted for the treatment of late metastases. The results in this group are very discouraging. There are 2 patients, however, with regional metastases who have been cured for a five-year period. Two others are free from disease fourteen months and two and a half years after treatment, respectively. Two died of intercurrent disease three years and four years, respectively, after treatment.

There were 84 secondary cases in this series, but only 24 were treated with any possibility of cure. Three of these are recent. We thus had 2 five-year cures out of 21 possible cases, with 2 patients

untraced The percentage of cures in this group was 9

Of all cases, both primary and secondary, there were 3 five-year cures out of a possible 35 in the group with regional metastases In the group without regional metastases, there were 12 five-year cures out of a possible 47 The curability of the operable cases in this series, then, was 9 per cent in cases with regional lymph-node involvement, and 25 in those without it

### CONCLUSIONS

The prognosis in malignant melanoma is very poor However, a few patients can be cured by adequate surgery

There is a high incidence of malignant melanomas on the lower extremities, and they represent more than half of the malignant tumors of the skin in this region

Malignant melanomas arise in congenital pigmented nevi or as spontaneous primary growths They rarely arise in pigmented, hairy nevi

Trauma to a pre-existing lesion is probably a factor in stimulation of lawless growth Cauterization or desiccation is dangerous

Metastases may occur through the skin lymphatics or the deep lymphatics or via the blood stream

Adequate surgical treatment includes wide local removal and thorough dissection of the regional nodes We realize that the latter procedure is not always feasible

In malignant melanomas of the eye, enucleation is adequate treatment

Roentgen therapy is extremely unsatisfactory, it rarely there is benefit It should be considered inoperable cases

Spontaneous regression may occur in the metastases

While the prognosis is particularly poor in cases with regional lymph-node involvement, an occasional cure may be obtained Patients should be given the benefit of adequate regional dissection

### CASE REPORTS

#### VE WITHOUT RECURRENCE

*Case 1* (M G H 268876) A 60-year-old woman was admitted to the Massachusetts General Hospital in 1925 with a pigmented lesion of the finger Amputation of the finger and epitrochlear and axillary dissections were performed, with a positive report on the finger and a negative one on the nodes She was recently examined and found to be well (Survival, 13½ years)

*Case 2* (private) A 47-year-old woman was admitted to the New England Deaconess Hospital in 1927 A black mole on her forearm had been removed 2 years before She complained of a large mass in the axilla with pressure on the nerves of the arm Dissection of the axilla was done with little expectation of anything more than relief The pathologist reported melanotic sarcoma in the

nodes The patient has been examined regularly since then and is free from recurrence. (Survival, 10 years.)

*Case 3* (M G H 296322) A 41 year-old man was admitted to the Massachusetts General Hospital in 1929 He complained of a tumor of the inner aspect of the leg of 4 years' duration There had been gradual growth and ulceration and the tumor had become pedunculated. Excision and saphenous dissection were done. The primary growth showed melanotic sarcoma, but the nodes were negative. A letter from the patient in 1938 stated that he was in good condition except for stomach symptoms which he had had for several years There has been no examination, but he is probably free of disease. (Survival, 9½ years)

*Case 4* (private) A 24 year-old man complained of failing vision. A pigmented tumor of the iris was found and enucleation was carried out by an ophthalmologist. The pathologist reported the tumor to be a malignant melanoma. The patient was free from disease 9½ years later

*Case 5* (M. G. H. 292449) A 25-year-old woman was admitted to the Massachusetts General Hospital in 1928 A nodule on the forearm appeared 2 years previously Three months before entry a node was felt in the epitrochlear region and 1 month later one in the axilla. The tumor was excised together with the epitrochlear and axillary nodes, all of which showed malignant melanoma The patient was examined and found free of disease in 1937 (Survival, 9 years)

*Case 6* (P H. 4252) A 63-year-old housewife entered the Pondville Hospital in February, 1932. She had had a mole on her back for 6 years Three weeks before admission it began to grow and the skin about it became inflamed Local examination showed an elevated crusted lesion of the skin overlying the lumbar spine. Wide excision of the lesion was done without regional dissection The pathological report was malignant melanoma. Since then she has been well and free of disease. (Survival, 6½ years)

*Case 7* (P H. 4272) A 51 year-old male entered the Pondville Hospital in February, 1932 Nine months before admission he had struck his heel and broken the skin. His shoe had kept this lesion irritated and a few weeks

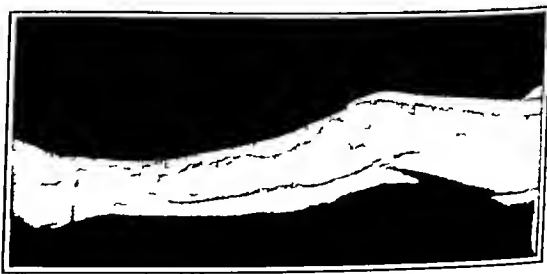

FIGURE 3 Case 7

*The recurrent nodules in the skin have been removed with the skin, subcutaneous tissue and fascia, and the defect grafted*

later his physician had cauterized it with silver nitrate. Six weeks before admission he had noticed a swelling in the right groin. An indurated growth 3 cm. in diameter was found on the inner aspect of the right heel There was a freely movable mass of nodes in the right saphenous

region. A wide excision of the local lesion together with a saphenous and inguinal dissection was done. The pathological report was amelanotic malignant melanoma with metastases to regional lymph nodes. Four months later the patient noticed nodules on the inner aspect of the leg and entered the hospital for excision of the skin of the inner side of the leg. This required multiple skin grafts (Fig 3). The nodules were amelanotic malignant melanomas. The excised skin measured 51 by 8 by 15 cm. He later had a recurrent nodule removed from the upper end of the scar but was free of disease 6½ years after treatment.

*Case 8* (P. H. 5309) A 52-year-old housewife was admitted to the Pondville Hospital in August, 1932. She had noticed poor vision in the left eye for a number of months. In the upper inner quadrant of the left eye the iris was bulging forward. Posterior to this there was an apparent hemorrhagic pigmented area of new growth. Enucleation of the eye was performed and a diagnosis of malignant melanoma of the iris was made. She has since been free of disease. (Survival, 6 years.)

*Case 9* (M. G. H., Baker, 9358) A 41-year-old woman was admitted to the Massachusetts General Hospital in March, 1933, for an abdominal operation. She called our attention to a pigmented mole on her back. This had been present for several years and had shown no recent change. It was excised with a wide margin and showed melanotic sarcoma. No regional dissection was done, as there were no palpable nodes in either axilla. The patient was apparently free of disease in September, 1938. (Survival 5½ years.)

*Case 10* (M. G. H. 330480) A 25-year-old woman was admitted to the Massachusetts General Hospital in 1933. A mole on the dorsum of the hand, which had been traumatized frequently, grew rapidly and spread to the axillary nodes. Amputation at mid forearm and dissection of the axilla were done. The pathologist reported a very rapidly growing melanotic sarcoma of the amelanotic type. A letter from the patient in 1938 stated that she was well. (Survival, 5 years.)

*Case 11* (M. G. H. 337411) A 62-year-old woman was admitted to the Massachusetts General Hospital in 1934 with a tumor over the malar prominence of 3 years duration. There had been a gradual increase in size, but there were no palpable nodes. Excision with a plastic closure was done, but there was no regional dissection. The pathological report was melanotic sarcoma. A letter from the patient in 1938 stated that she was well. (Survival, 4½ years.)

*Case 12* (P. H. 4412) A 34-year-old man was admitted to the Pondville Hospital in March, 1932, with a growth on his leg of 12 years duration. There had been rapid growth for 1 year without antecedent trauma. The lesion was elevated, non-ulcerated, and slightly bluish. Only wide local excision was performed. Since then, he has been well. (Survival, 4½ years.)

*Case 13* (M. G. H. 339669) A 63-year-old woman was admitted to the Massachusetts General Hospital in 1934 with a lesion on the sole of the foot. This had been desiccated in the Out Patient Department 2 weeks previously but had promptly recurred. A wide excision was done without regional dissection, with a report of melanotic sarcoma. A letter from the patient 4 years later stated that she was well. (Survival, 4 years.)

*Case 14* (M. G. H. 307524) A 43-year-old woman was admitted to the Massachusetts General Hospital in 1930 with a lesion 2.5 by 2.5 cm. on the chest wall. This was excised and reported to be a malignant melanoma. Five years later there was a local recurrence and a second excision was done, with a positive pathological examination. No regional dissection was done. The patient was free from disease in 1938. (Survival, 8 years.)

FIGURE 4 Malignant Melanoma of the Foot  
Partial amputation was performed. Dissection was advised but refused. The case is now untraced.

*Case 15* (M. G. H. 85397) A 27-year-old woman was admitted to the Massachusetts General Hospital in 1935 with a pigmented lesion on the buttock. A wide excision with a saphenous and groin dissection was done. Pathologically this was a melanotic sarcoma with positive nodes. There was a recurrence in the scar 2½ years later but no further trouble in the regional drainage area. The second pathological report was positive.

*Case 16* (P. H. 10536) A 64-year-old housewife entered the Pondville Hospital in March, 1936. She had been blind in the left eye for 13 years. An enucleation of the eye had been done at an outside hospital 1 month before admission. Examination showed a mass of red tissue covered with mucous membrane protruding between the eyelids. An exenteration of the left orbit was performed and a diagnosis of malignant melanoma was made. The patient was living and well 2½ years after operation.

*Case 17* (P. H. 9797) A 15-year-old girl entered the Pondville Hospital in August, 1935. A birthmark on the left cheek had grown larger and blacker since birth. A pigmented nevus 3 mm. in diameter was removed, and the pathological report was that of malignant melanoma. No neck dissection was done. There was no evidence of recurrence 2 years after treatment.

*Case 18* (P. H. 11116) A 52-year-old woman was admitted to the Pondville Hospital in July, 1936. She had had a mole on the neck for 5 years. Recently it had grown larger and become black. Examination showed an irregularly shaped, deeply pigmented nevus 1 cm. in diameter just above the clavicle and just to the right of the

midline of the neck. Wide excision was performed, but no regional dissection, as one of the primary lymphatic drainage areas was to the nodes of the mediastinum. The patient was well and free of disease 2 years after excision.

**Case 19 (P H 11745)** A 42 year-old housewife entered the Pondville Hospital in November, 1936. For 10 years she had noticed a firm swelling over the distal joint of the left great toe. The swelling gradually increased. On the

FIGURE 5 *Malignant Melanoma of the Great Toe*  
*This patient died ten months after operation*

dorsum of the left great toe, a large, lobulated, slightly purplish, firm tumor was found. The tumor was found to be encapsulated and was excised locally. No saphenous or inguinal dissection was done. The diagnosis was that of malignant melanoma. The patient was well and free of disease 22 months after the local excision.

**Case 20 (P H 8521)** A 32 year-old housewife entered the Pondville Hospital in July, 1937. A birthmark just below the right ear had started to increase in size 7 weeks before admission. A wide excision of the lesion was done, followed by neck dissection 3 months later, postponed because of a low grade dermatitis. The pathological report was malignant melanoma without metastases to the regional lymph nodes. Soft nodes overlying the sternomastoid muscle were removed in 1938. These were negative. The patient was well and free of disease 14 months after treatment.

**Case 21 (P H. 12606)** A 36-year-old woman was admitted to the Pondville Hospital in June, 1937. Two years before admission she had had a mole removed by freezing. The mole had been present only a few months but was black and ulcerated. A month after removal a small lump was felt in the region of the trapezius muscle. This had gradually increased in size. Examination showed a 7-cm. mass in the subcutaneous tissue in the region of the trapezius muscle. There was no recurrence locally, and

the mass was removed together with a dissection of the posterior carotid triangle. The pathological report was malignant melanoma with metastases to the cervical lymph nodes. The patient was well and free of disease 14 months after operation.

**Case 22 (P H 12780)** A 66-year-old man was admitted to the Pondville Hospital in July, 1937. He had had a smooth, slowly growing mole on the left cheek for 15 years. He had noticed that this was becoming thicker. Examination showed an irregular, black, movable lesion in the center of the left cheek. In the central portion of the lesion there was a warty, raised, thickened area. A wide local excision with plastic closure was done. The diagnosis was that of malignant melanoma. No neck dissection was done. The patient was well and free of disease 13 months after operation.

**Case 23 (P H. 11908)** A 49-year-old housewife was admitted to the Pondville Hospital in January, 1937. Six months before admission she noticed a lump near her rectum. Four weeks previously part of the tumor was removed and the pathological report was melanotic sarcoma. A radical excision of the scar was performed and only one focus of tumor cells was found in the specimen. Five months later a node was found in the right groin, and inguinal and saphenous dissections were done. Nodes were positive for metastatic malignant melanoma. The patient was well and free of disease 18 months after the primary excision and 12 months after the inguinal and saphenous dissections.

**Case 24 (M G H. 100780)** A 33-year-old woman was admitted to the Massachusetts General Hospital in December, 1937, with a black mole on the neck below the ear. A wide local excision was performed and the mole was found to be a malignant melanoma. A radical neck dissection was performed 1 month later but the nodes were negative for tumor. One lymph node which lay above the clavicle appeared black grossly, but anthracosis was found microscopically. The patient was apparently free of disease in August, 1938. (Survival, 9 months)

**Case 25 (M G H., Baker, 107537)** A 41 year-old woman was admitted to the Massachusetts General Hospital in February, 1938. A pigmented mole on the instep which had been present since birth had changed in appearance and had become sore over a period of 8 months. Examination showed a flat, brown lesion 2.5 by 2 cm., the center of which was raised, indurated and pinkish. Clinically the center appeared malignant and the periphery benign. This proved to be the case when the lesion was excised. A dissection of the saphenous and inguinal regions was done 6 days later and negative nodes were found. There has been no recurrence in the 7½ months since operation.

**Case 26 (W S., Cancer Section, 258)** A 57 year-old woman was admitted to the Westfield Sanatorium in March, 1938, with a lesion on the cornea. One year before a similar lesion had been treated by radium, apparently with benefit. Biopsy showed a melanotic sarcoma of the amelanotic type. The eye was enucleated. The patient was apparently well 6 months later.

**Case 27 (M G H., Phillips House, 106785)** A 77 year-old man was admitted to the Massachusetts General Hospital in January, 1938, with a black mole of 5 years duration on his back but with recent enlargement. Several other flatter lesions with less pigment had been treated by

a dermatologist with radium over a period of 2 years. He had advised against treatment of any sort for the black mole. However, excision was done and a positive report obtained. This patient has been followed for about 6 months and is apparently well.

**Case 28** (W S, Cancer Section, 449) A 22-year-old woman was admitted to the Westfield Sanatorium in May, 1938, with a lesion on the lower eyelid of 1 month's duration. It had been treated by an electric needle before entry. Excision was done at once, and the report was amelanotic sarcoma. Because the removal did not appear to be wide enough for this type of tumor, a wider removal was done by excising half the eyelid and reconstructing a new eyelid. The second microscopic examination showed more of the same type of tumor. This patient has been followed for but 2 months after operation.

**Case 29** (M. G. H., Baker, 131786) A 68-year-old man was seen in consultation in May, 1938. He said that a pigmented tumor had been present on his face for 4 years. Two years previously he had been treated with an electric needle and the tumor had partially disappeared. Six weeks before examination a node had appeared in his neck. Operation was advised and accepted. The primary tumor together with the skin between it and the node was removed, and a radical dissection of the neck was done. Pathologically this was melanotic sarcoma with metastasis in a node adherent to the parotid gland. This is a very recent case and has been followed but 2 months.

DIED WITHOUT RECURRENCE AFTER FIVE YEARS

**Case 30** (M. G. H. 200519) A 60-year-old man was admitted to the Massachusetts General Hospital in 1915. A mole on the leg of 10 years' duration broke down and crusted over. A wide excision with saphenous and inguinal dissection was done. The primary lesion showed melanotic sarcoma, but the nodes were negative. The patient was found free of disease 2 years later. He died of other causes in 1936 (Survival, 21 years).

**Case 31** (M. G. H. 295000) A 74-year-old man was admitted to the Massachusetts General Hospital in 1928 with a nodule on his back measuring 5 by 6 cm. Excision was done and the tumor was found to be a melanotic sarcoma. There was an immediate recurrence and a second excision, again with a positive report. The patient died without recurrence 5 years later.

**Case 32** (M. G. H. 268397) A 75-year-old woman was admitted to the Massachusetts General Hospital in 1925 with a 2-by-2-cm. pigmented mole on the cheek. The lesion was excised and reported to be a malignant melanoma. The patient died 10 years later without recurrence.

TREATMENT BY X RAY

**Case 33** (M. G. H. Baker, 15387) A 67-year-old man was seen in consultation in June, 1936. A short time previously he had been operated on for a large tumor in the femoral region. The tumor proved to be unremovable. It was a rapidly growing amelanotic type of malignant melanoma. When examined he had a large mass in the inguinal and saphenous region and the tumor could be felt in the pelvis. There was some swelling of the leg and a lymph sinus in the wound. X-ray treatment was given to the mass as a palliative measure. A total of 4000 r (200 kilovolts) was given through a 15-by-15-cm. field to the mass in the pelvis, groin and saphenous region, the treatment being spaced over 2 weeks. There was immediate regression and disappearance of the tumor. Three months later the patient complained of a

severe cough. A chest plate showed probable pulmonary metastases. He was given 800 r both to the front and the back of the chest. His cough cleared up at once. During the 2½ years since treatment he has had no recurrence of the tumor in the groin. Chest plates show no changes. He is free from symptoms and is able to continue at his work.\*

**Case 34** (P. H. 13063) A 64-year-old man was admitted to the Phillips House in September, 1937. He had had a mole on his back in the region of the scapula for several years. Ten months before admission this became sore and was excised by his doctor. Three weeks later his neck began to enlarge, and nodes were later noted in his axilla. Two months previously he had noted nodes in his groin. Examination showed a diffuse, hard mass above the clavicle, and a baseball-sized mass in the axilla which was adherent to the deep structures. A chest plate showed no evidence of metastatic disease. The patient received 1200 r to the right axilla, right supraclavicular area and scrofum in October, 1937. The masses in the axilla and supraclavicular areas showed regression, and in December, 1937, he received an additional 600 r to each of these areas. In March, 1938, further radiation, 1200 r to the axilla and 600 r to the groin, was given.

#### CASE WITH SPONTANEOUS REGRESSION

**Case 35** (P. H. 1064) A 43-year-old man was admitted to the Pondville Hospital in January, 1929. Two years before admission he had had the 5th toe removed for a black tumor. An inguinal dissection had been done. Several months before admission he had had erysipelas of the lower leg, followed by the appearance of black nodules. Multiple nodules were found over the lower leg, and there was a fixed mass in the groin but no nodules above the operative area. The case was considered inoperable and no treatment was given. A year later the masses in the thigh began to disappear, leaving only the pigment. The masses in the thigh finally disappeared, and the patient died of probable brain metastases 6 years after his first admission.

#### DISCUSSION

DR. GEORGE F. DWINELL, Manchester, New Hampshire. This is a peculiarly difficult subject to discuss because we do not see very many of these cases. One hundred and fifty-eight cases is an unusual number to report. I have

This patient died in March, 1939, following operation for a strangulated hernia. An autopsy showed no trace of his original tumor and no metastases.

looked up several series, and 50, I believe, was the next highest number that anyone reported, and I think this series shows results about as good as are shown elsewhere. Twenty per cent is a high incidence of five-year cures

We have no large series in Manchester, and I have not attempted, nor has Dr Wilkins, to look up all our cases, but he has asked me to bring before the society that following a definite routine which he has adopted, and which I have used, we have 3 outstanding cures. One is that of a patient with a lesion on the face who has had no recurrence for over ten years (The mortality is very high in face cases). The other 2 had lesions of the extremities. One of the latter came to me three years ago, and I did not think of the possibility of melanoma. I took a biopsy, thinking the case was probably one of fibrosarcoma, and that was the report which the pathologist made on the little piece that I sent him, but later I dissected the nodes of the groin and found a typical melanosarcoma.

The point which Dr Wilkins wishes me to bring out is that perhaps we have been a little bit lax in our treatment. These cases must be handled perhaps a little more radically than Dr Daland and Dr Holmes brought out. All our modalities should be used. The method we use consists, in the first place, of large doses of buried radium, not in the lesion but surrounding it, and also radium on the surface. By large doses I mean 1800 mg hours—200 mg of needles and tubes buried around the lesion for nine or ten hours. This is to be followed in about three weeks, at which time the height of the radium reaction is supposed to occur, by complete excision. This means wide excision, at least 1 cm. away from the lesion, extreme care being taken not to touch the lesion. Furthermore—and Dr Daland does not agree in this—we believe that dissection of the nodes should be deferred for two or three weeks. As you know, melanoma gives a very peculiar pathological picture. It does not travel the way that ordinary cancer cells travel. It travels in the skin, usually just under the surface. Our idea was to allow these cells to reach the lymph nodes and be caught there before dissection. We follow up the regional lymph node dissection with a thorough course of deep x-ray therapy.

After this I do not believe that any more can be done. The 3 cases previously mentioned have been treated by this method, and have remained free from recurrences for ten, three and three years respectively.

This is the main point that Dr Wilkins wished me to bring out that we ought to do a little more than we have in the past for these cases, and should not merely say

that radium has no effect. The effect of our initial radiation, I think, is purely and simply one of fibrosis. All these tumors practically disappear. I do not believe that the radium kills the growth, but that loss of nutrition does, however the method is worth trying in the way that Dr Wilkins suggests.

DR. EDWARD H. RISLEY, Waterville, Maine. I should like to emphasize a point which I have only recently learned from a bitter experience. I think most of us have always assumed that a melanotic tumor could be recognized by the melanosis in the tumor itself. I find that this is not so. There are many small tumors which appear on the forearm, and on other extremities, which look like small fibromas or some other form of tumor, but which on removal turn out to be malignant melanomas.

I operated on a woman of thirty six for what felt like a fibroma on the forearm. I excised it with the endotherm and found that she had no diseased nodes in the axilla. The pathological report was malignant melanoma. In July the patient had a well-developed metastasis in the axilla, and the following December she died of a brain metastasis.

I have seen one other case of a similar nature, and I believe we should not do biopsies on these tumors of the extremities, we should excise them and then get our diagnosis, rather than depend on a biopsy, which is many times not a safe procedure.

DR. GRANTLEY W. TAYLOR, Boston. I should like to ask whether Dr Daland and Dr Holmes have a program of therapy for pigmented nevi.

DR. DALAND (closing). We found no case with a history of hair in the nevi, nor have we found any described in the literature. There was only 1 case with a lesion on the scalp. Adair has quoted a study of 250 patients who had an average of twenty pigmented nevi per patient. We may talk about removing all pigmented nevi, twenty from each of 250 patients, but it cannot be done. There are not enough surgeons to do it, but if there is a pigmented nevus in a place where it is subject to any type of irritation, it should be excised and not be treated by desiccation.

I am glad that Dr Risley brought out his point. Fully half these cases show no pigment, but I want to emphasize again that most malignant tumors of the skin of the leg are carcinomas or malignant melanomas, and should be excised. Let the pathologist see the tumor after it has been removed in its entirety.

## THE TREATMENT OF CHRONIC PRURITUS VULVAE WITH LOCAL APPLICATIONS OF ESTROGEN\*

ALBERT Y. KEVORKIAN, M.D.†

BOSTON

THERE are few conditions which confront the physician that are more resistant to treatment than is chronic pruritus vulvae associated with leukoplakic and kraurotic changes of the labial skin. The intolerable itching frequently assumes such proportions that, despite attempts at palliation with antipruritic salves or lotions, alcoholic injections and exposure to x-rays, there is continual psychic trauma and loss of sleep, resulting in general physical debility. These cases, to which no demonstrable cause has as yet been assigned, may be classified as an essential type as differentiated from the commoner type in which the skin changes are not a prominent feature and the causative factor or factors are apparent and remediable.

Cases of pruritus vulvae other than the essential type are the result of local irritation from chronic cervicitis, trichomonas vaginalis vaginitis, infection with the epidermophyton, diabetic or infected urine or obesity with gross uncleanness. This type rarely continues to the chronic state, because adequate treatment directed to the removal of these respective causative factors relieves the patient of her symptoms.

It is the purpose of this paper to present a hypothesis for the pathogenesis of the essential type of chronic pruritus vulvae with leukoplakic and kraurotic changes, and to report the results following treatment of a group of 4 cases with locally applied estrogenic substances. The collective term "leukoplakic vulvitis" will be used in referring to these cases.

Although the results following denervation of the affected area offer some encouragement in the control of this condition, the permanency of relief is not established and the procedure is contraindicated in some 40 per cent of cases (Learmonth et al.,<sup>1</sup> Montgomery et al.<sup>2</sup> and Usher and Campbell<sup>3</sup>). A still more radical approach to therapy is vulvectomy, which is not infrequently followed by considerable local discomfort and frequent recurrences. Vulvectomy has its usefulness in cases of malignancy, or in cases where malignant changes are anticipated.

Disturbance in ovarian function has for many years been considered an etiologic factor in leukoplakic vulvitis, but it has not been proved

an important one. The most probable reason for this may well be the fact that substitutive treatment with estrogenic hormones has proved unsatisfactory. In most cases, however, this treatment has been started many years after pruritus, the first and frequently the only symptom, was noted by the patient.

There are many facts which support the theory of decreased ovarian function as a contributing causative factor. The statistics of reported series show that the average age of occurrence of leukoplakic vulvitis is 52 years, an age well past the time when the ovary begins to fail in function. The region of the vulva in women may possibly be considered as a true "sexual skin." In the monkey and in certain of the great apes that skin about the vulvar and gluteal regions manifests marked vascular changes coincident with the follicular phase of the menstrual cycle. This great reddening and edema seen in young animals at the time of ovulation has been shown to be due to the unopposed action of estrogen (Allen<sup>4</sup>). Although no such sexual skin has been demonstrated in the human being, it appears likely that a homologous area may exist and be specifically affected by estrogen. Such a concept receives support from the observation that considerable atrophy of the vulva normally follows castration and the menopause. It is quite conceivable that this physiologic atrophy may render the cutaneous area more liable to pathologic changes incident to any damaging influence.

There is significant histological evidence that in the cases under consideration there is a progressive disintegration of the elastic fibers in the corium. This loss of elasticity, together with the epithelial changes, results in a thickened and rigid skin which cracks easily, opening portals for subepithelial infection. Several factors may then irritate the nerve endings sufficiently to produce a sensation of itching. Once pruritus is established, the constant trauma of scratching inevitably leads to excoriation of the skin, and eventually to a chronic pathologic state with hyperplasia and sclerosis in variable proportions.

Parenteral estrogen therapy has offered relief to only a small percentage of women suffering from leukoplakic vulvitis. As stated above, the treatment has in most cases been instituted many years after the onset of symptoms, conceivably

From the Surgical Clinic of the Peter Bent Brigham Hospital, Boston.  
†Research fellow in surgery, Harvard Medical School; voluntary graduate assistant in surgery, Peter Bent Brigham Hospital.

after the local changes have been established for a long time

It appears that parenterally administered estrogen, even in large amounts, is less efficacious in local conditions than smaller amounts locally applied. This has been shown to be true in treating Neisserian vaginitis in children and young girls before puberty, and senile vaginitis at or after the menopause. Lyons and Templeton<sup>5</sup> have shown that locally applied estrogen is two hundred times as effective as parenteral estrogen on the vagina of a rat. In view of the rapid destruction of estrogen in the organism (Dingemanse and Laqueur<sup>6</sup>), it seems reasonable to expect that constant and continuous local action of estrogen can be better attained by frequent local applications. That estrogen is readily absorbed when applied to the human skin has been shown by Salmon<sup>7</sup>, Zondek,<sup>8</sup> and subsequently Klasten<sup>9</sup> and Reifferscheid,<sup>10</sup> reported successful therapy of pruritus vulvae by local percutaneous application of estrogen combined with large doses parenterally by injection. While this investigation was in progress it was noted that these earlier investigators<sup>8, 9, 10</sup> had used the estrogenic material in the form of a salve. Following their suggestion a lanolin base was used in the later treatment of the cases reported below. This has the advantage of greater ease of application and has proved just as efficient a vehicle as sesame oil. Local application has therefore been employed in the therapy of the cases reported below.

#### METHOD

The vulva and epipubic and perineal skin are thoroughly cleaned and dried. Estradiol\* in sesame oil (0.5 mg per cubic centimeter) is thoroughly massaged into the skin of the affected area. One cubic centimeter (60,000 international units) is used for each inunction at two- to six-day intervals. The patients are instructed to use no additional treatment. After the pruritus is controlled, smaller amounts, in the form of a salve with a lanolin base, are applied daily by the patient.

#### CASE REPORTS

*Case 1* A. D., a 44 year-old woman, who had had five children, was seen on June 24, 1938. A persistent, severe pruritus vulvae of 2 years' duration had not been influenced by any of various antipruritic ointments or lotions. There was no associated leukorrhea, glycosuria or infected urine. In August, 1935, the intrauterine application of 1200 mg hr of radium for functional bleeding was followed by amenorrhea until August, 1936, when there was another

application of 1200 mg hr of radium for recrudescence of bleeding. There had been no further bleeding.

Physical examination showed extensive whitening of the skin of the labia majora with markedly thickened plaques of leukoplakia extending to the epipubic region. The labia minora were atrophic, and the vulvar orifice was narrowed. There were several excoriations. The uterus, cervix and vagina were atrophic.

An inunction of 60,000 units was applied on the first day. In 2 days, considerable relief was noted, and complete relief followed the application of 255,000 units over a 16-day period. Treatment was discontinued in order to determine the permanency of relief. No bleeding occurred after the withdrawal of estrin. After 6 weeks of complete relief there was a recurrence of the pruritus. One inunction of 60,000 units on August 26 brought about relief. The patient was then given a salve with a lanolin base containing 20,000 units of Estradiol per gram. By applying a small amount every evening she has remained symptom free for 3 months, having used 20 gm. of the ointment.

*Case 2* E. G., a 72 year-old woman, who had had one child, was seen on July 1, 1938. The menopause had occurred 22 years previously. Persistent pruritus vulvae of several years' duration had been associated for the previous 2 years with marked incontinence of urine. On April 5, 1938, a plastic repair was performed, with only partial relief of the incontinence and no influence on the pruritus.

Physical examination showed extensive involvement of the labia majora by multiple plaques of white, thickened epithelium. This extended to the thighs and the epipubic and perianal regions. The labia minora were replaced by thickened, white, shiny skin, and there was marked narrowing of the vulvar orifice. The entire area was moist, and there were many deep excoriations with secondary infection. The cervix and uterus were atrophic.

Six applications of approximately 60,000 units each, over 4 weeks, resulted in considerable but not complete subjective relief. However, in spite of the complaint of continued pruritus the excoriations incident to the long practiced scratching disappeared. Inasmuch as the incontinence was not corrected, it appears that in this case the irritation from the urine played a part in the production of the pruritus. However, with daily applications of small amounts of a lanolin salve containing 60,000 units of Estradiol per gram the patient has had sufficient relief to allow uninterrupted sleep.

*Case 3* J. K., a 35-year-old woman, who had had two children, was seen on July 25, 1938. Persistent pruritus vulvae of 3 years' duration was associated with vaginal discharge due to a chronic cervicitis with polyposis of the endocervical canal. Catamenia were regular and normal. Excision of the polyps and cauterization of the canal with a post-cautery in April, 1938, was followed by a diminution but not complete disappearance of the discharge. There was, however, no relief from the pruritus, and treatment with antipruritic salves and lotions was without effect.

Physical examination showed marked thickening of the vulva and of the perineal skin extending to the epipubic and perianal regions. The skin was grayish, and there were many excoriations. The cervix was well healed, and the canal smooth. There was, however, some purulent discharge from the endocervix at the internal os. The uterus and adnexa were normal.

\*The estrogenic material and the lanolin salve were prepared and furnished through the courtesy of Dr. Max Gilbert of the Schering Corporation, Bloomfield, New Jersey.

Three applications of 60,000 units of Estradiol in oil, at weekly intervals, followed by five applications of 30,000 units at 3-day intervals, resulted in marked though not complete subjective relief. The attacks, however, were of short duration as opposed to attacks before treatment lasting for hours. The vulvar skin appeared more normal and was less thickened and there were no excoriations.

The patient was given a lanolin salve containing 60,000 units of Estradiol per gram. By applying a small amount every evening, the patient has since experienced complete relief from the pruritus.

*Case 4.* L. N., a 44-year-old woman, who had had two children, was seen on August 12, 1938. There was persistent though mild pruritus vulvae of 16 years duration, associated with vaginal discharge and chronic cervicitis with polyposis of the endocervical canal. Catamenia were regular and normal. Excision of the polyps and cauterization of the cervical canal with a post-cautery were followed by a disappearance of the discharge. Relief of the pruritus was then noted except for an area in the epipubic region.

Physical examination showed the vulva to be normal in appearance except anteriorly in the epipubic region, where the skin was white, markedly thickened and excoriated. The cervix was well epithelialized, the canal smooth and there was no discharge. The uterus and adnexa were normal.

Over a 31-day period, 220,000 units of Estradiol in oil was applied to the affected area in daily divided doses. This was followed by relief of the pruritus and disappearance of the excoriations. By daily using a small amount of lanolin salve containing 60,000 units of Estradiol per gram, the patient has remained symptom free. She was last seen, October 17, when the skin of the epipubic area was normal in color and texture.

It is apparent from these reports that the local application of a strong solution of estrogen has effectively remedied both the subjective symptoms and objective signs of pruritus vulvae. It is significant in this investigation that the psychological factors have been eliminated, in that objective criteria have been used in measuring the degree of relief. The patient's subjective sensations did not influence the objective sign of pruritus, namely the inevitable excoriations of the skin. The disappearance of these lesions can be accepted as evidence that the symptom had been relieved, if

not completely cured. This objective evidence of relief was found in all the cases cited.

The noted effects can scarcely be ascribed to the oil, because all cases had been treated with emollient salves without any effect, and one patient (Case 2) experienced no relief of pruritus with daily inunctions of oil over a trial period of seven days. It was also observed that the relief obtained with a preparation containing 20,000 units of Estradiol per cubic centimeter of oil was very transient as compared with that obtained by using the more potent preparation (60,000 units).

#### CONCLUSIONS

A hypothesis for the pathogenesis of leukoplakic vulvitis on an endocrinological basis is presented.

A simple method of treating leukoplakic vulvitis by local application of estrogen is offered. It is recommended because continuous local action simulating normal physiological conditions may conceivably be attained by frequent inunctions by the patient.

The results obtained in treating a small group of 4 cases justify further investigations on selected cases to determine more definitely the doses required and the permanency of relief.

## AN OUTBREAK OF INFECTIOUS DIARRHEA AMONG NEWBORN INFANTS

ARTHUR M. KIMBERLY, M.D.\*

WORCESTER, MASSACHUSETTS

**D**URING November, 1937, an extremely disastrous epidemic of infectious diarrhea broke out among a group of newborn infants on the Pediatric Service of the Worcester Memorial Hospital. The clinical features and pathologic findings closely resembled those described by Rice and others<sup>1</sup> in their report on sixteen outbreaks of infectious diarrhea occurring in the nurseries of eleven hospitals in New York City. We have reason to believe that our cases arose directly following the admission to the ward of an infant who had been discharged six days before from a hospital in New York City.

By overcoming the natural reluctance of any one hospital to report its disastrous results, Dr. Rice, who is Health Commissioner of New York City, and his collaborators are to be highly commended for correlating and reporting the experiences of these hospitals. They contend that the cases of diarrhea covered in their report constitute a distinct disease entity, basing their argument on the following grounds: exact similarity of clinical picture, specificity of age group, the occurrence being exclusively among newborn infants, uniformly high morbidity and mortality rates (46 per cent mortality among 505 infants), highly contagious nature of the infection, inability to identify the causative organisms by ordinary bacteriological measures, and extremely mild pathologic findings referable to the gastrointestinal tract, associated, however, with secondary pyogenic infections. The cases here reported fulfill these criteria exactly.

We were extremely unfortunate in the group of infants that were housed on our Pediatric Service when the epidemic developed. As the highly infectious nature of this diarrhea became apparent, we placed the babies under increasingly strict isolation precautions, until finally each surviving infant was in a room by itself under entirely separate nursing care. Through prompt removal from the ward, two postoperative cases of hypertrophic pyloric stenosis were protected from infection. It is important to enumerate the facts concerning the babies who acquired the infection.

*Case 1* D, a girl, was admitted to the hospital November 10, 1937, when 1 month old, the birth weight had been 7 lb. One week previously she had been discharged from

a New York City hospital, where she had been exposed to a case of diarrhea. On admission she weighed 5 lb., 15 oz., she was vomiting and having frequent loose movements, and appeared extremely toxic.

*Case 2* P, a premature boy, was born outside the hospital and brought immediately to it, the birth weight had been 3 lb., 3 oz. At 1 month the weight had increased to 4 lb., 7 oz. The diarrhea started November 11. Several temperature reactions occurring previously were thought to be due to instability of his temperature-control mechanism.

*Case 3* G1, a girl, was one of twins born in the hospital, the birth weight had been 4 lb., 2 oz. This infant offered considerable difficulty in taking her feedings, and on the 20th postpartum day (November 11), when she began to vomit and have loose, green stools, she weighed 4 lb., 5 oz.

*Case 4* G2, a twin sister of Case 3, had weighed 4 lb., 4 oz., at birth. This infant also presented difficulty in feeding, and on the 21st postpartum day (November 12), when diarrhea began, she weighed 4 lb., 12 oz.

*Case 5* B, a boy, was born during the course of pneumonia of his mother, the birth weight had been 7 lb., 12 oz. When 1 week old, he was weaned and placed on a formula, at this time the weight was 6 lb., 14 oz. The following morning (November 16) six or eight loose, greenish yellow movements occurred.

*Case 6* F, a boy, was referred, when 6 days old, from an out-of-town hospital for correction of a complete cleft palate and left harelip, the birth weight had been about 6 lb. On admission his weight was 5 lb., 10 oz. Because of his handicap, considerable difficulty was experienced in feeding, and at the onset of the diarrhea on November 18, when he was 21 days old, he weighed 6 lb., 2 oz.

Table 1 presents a summary of the clinical experiences with these 6 infants in course of their infectious diarrhea.

The mortality of this series is extremely high, the highest, in fact, of any of the reported series of cases. However, it is not inconsistent with an infection which extracted a case mortality of 46 per cent from the average run of healthy newborn infants who acquired the disease. Five of the 6 babies who acquired the disease succumbed to it. As appears from the above description, it would be hard to select a group of babies constituting a less favorable risk than those who acquired this infection in our ward. The infants were all within the age period which appears peculiarly susceptible to this disease. Although born of a mother who went into labor and delivered during the active course of pneumonia, Case 5, the sole survivor,

\*Pediatrician, Worcester Memorial Hospital.

was the only apparently normal infant in the group

On the second or third day of their illness, when they were passing frequent loose or watery movements, the babies began to vomit. So far as we could see, it made little difference whether tap water, cereal water, weak tea or any of the various formulas was fed, even though given in small quantities and in great dilution. The babies at this stage vomited everything taken. By dint of repeated administration of 5 per cent glucose in

The following pathological summary is based on autopsies performed by the pathologist, Dr. James Beck, on Cases 3, 4 and 6. The findings in the gastrointestinal tract were remarkably similar in each case and closely resembled those reported in other series. They were notable for their mildness. The mucosa of the stomach appeared pale and was covered by a thin film of mucous material. The duodenum showed a moderate injection. The mucosa of the entire intestinal tract was thin, yellowish and smooth. There were no

TABLE 1 Summary of Clinical Courses

CASE NO.	STOOLS	THERAPY	FEEDINGS	SYMPTOMS AND COMPLICATIONS	OUTCOME
1	8-10 daily yellow soft to yellow green watery	Clyses and intravenous glucose prostigmin	Pectin agar-protein milk starvation with rice water	Temp 100-102°F vomiting distention convulsions cellulitis terminal pneumonia	Death on 12th day weight 5 lb 4 oz. autopsy refused.
2	4-6 daily yellow soft to green watery	Clyses subcutaneous blood prostigmin	Dilute evaporated milk raw scraped apple protein milk.	Temp 99-100°F distention vomiting probably terminal pneumonia	Death on 8th day weight 4 lb autopsy refused
3	6-8 daily yellow loose to green watery	Clyses subcutaneous blood prostigmin buffer solution	Olac dilute pectin agar-rice water	Temp 102-103°F vomiting distention hematemesis terminal pneumonia	Death on 11th day weight 4 lb 11 oz. autopsy obtained
4	6-8 daily yellow loose to green watery	Clyses and intravenous glucose transfusion (60 cc citrated blood)	Olac pectin agar-rice water-protein milk.	Temp 102-104°F vomiting distention terminal respiratory complications.	Death on 14th day weight 4 lb 5 oz. autopsy obtained.
5	5-9 daily yellow loose to green watery	Clyses transfusion (60-100 cc. citrated blood) starvation 48 and 60 hr	Stepped up protein milk rice water dilute skimmed milk.	Temp 97-103°F distention	Complete recovery discharged on 25th day weight 6 lb
6	4-8 daily yellow loose to green, watery (formed before death)	Clyses and intravenous glucose 4 transfusions (40-100 cc. citrated blood) starvation 48 and 72 hr	Dilute skimmed milk breast milk, rice water-stepped up protein milk.	Temp 99-103°F vomiting distention cellulitis probable pneumonia.	Death on 30th day weight 4 lb 13 oz. autopsy obtained.

saline and frequent injections of whole blood those babies who succumbed were kept alive in the order reported in Table 1, for twelve, eight, eleven, fourteen and thirty days. In view of the prematurity and other handicaps suffered by these babies at the onset of their illness they were rapidly exhausted by the constant vomiting and diarrhea. We were aware that the supportive measures of glucose, fluid and blood administration were only partly meeting the demands of this disease. An attempt was made to supply vitamins in concentrated form, but it is doubtful whether much if any was absorbed. As their general resistance was lowered, one after another acquired some sort of pyogenic infection. Two infants (Cases 1 and 6) developed subcutaneous infections at the sites of repeated injections. Nearly all the infants acquired some kind of respiratory infection. It is interesting that there were relatively few stools in comparison with the toxemia and prostration. An extremely trying feature in the clinical course was the severe and persistent abdominal distention. The cause appeared to be an adynamic condition of the intestinal musculature rather than excessive fermentation.

ulcerations or areas of hemorrhage. The loops of the bowel were distended by an odorless gas. Peyer's patches showed no enlargement. The mucosa of the colon was negative. Microscopically there was a minimum change throughout. This consisted of a moderate edema of the entire wall of the bowel, with only slight and scattered areas of leukocytic infiltration. There appeared a slight distention of the intestinal vessels, with diapedesis of blood corpuscles and hemorrhage in places. In Case 6, in which peritonitis was found, the serosa showed a mild inflammatory reaction and was covered with a small amount of exudate. All 3 of the autopsied babies showed parenchymatous degeneration of the liver, kidneys and heart, with fatty degeneration of the liver. Cases 3 and 4 showed edema of the lungs, with aspiration bronchitis from foreign material. Besides peritonitis, Case 6 showed a bilateral empyema and the congenital anomalies of cleft palate and left harelip, right cryptorchidism and Meckel's diverticulum.

The finding of *Bacillus welchii* as the predominating organism in the stools of several babies in our series is not regarded by us as being significant. No clinical or bacteriological evidence

## AN OUTBREAK OF INFECTIOUS DIARRHEA AMONG NEWBORN INFANTS

ARTHUR M. KIMBERLY, M.D.\*

WORCESTER, MASSACHUSETTS

**D**URING November, 1937, an extremely disastrous epidemic of infectious diarrhea broke out among a group of newborn infants on the Pediatric Service of the Worcester Memorial Hospital. The clinical features and pathologic findings closely resembled those described by Rice and others<sup>1</sup> in their report on sixteen outbreaks of infectious diarrhea occurring in the nurseries of eleven hospitals in New York City. We have reason to believe that our cases arose directly following the admission to the ward of an infant who had been discharged six days before from a hospital in New York City.

By overcoming the natural reluctance of any one hospital to report its disastrous results, Dr Rice, who is Health Commissioner of New York City, and his collaborators are to be highly commended for correlating and reporting the experiences of these hospitals. They contend that the cases of diarrhea covered in their report constitute a distinct disease entity, basing their argument on the following grounds: exact similarity of clinical picture, specificity of age group, the occurrence being exclusively among newborn infants, uniformly high morbidity and mortality rates (46 per cent mortality among 505 infants), highly contagious nature of the infection, inability to identify the causative organisms by ordinary bacteriological measures, and extremely mild pathologic findings referable to the gastrointestinal tract, associated, however, with secondary pyogenic infections. The cases here reported fulfill these criteria exactly.

We were extremely unfortunate in the group of infants that were housed on our Pediatric Service when the epidemic developed. As the highly infectious nature of this diarrhea became apparent, we placed the babies under increasingly strict isolation precautions, until finally each surviving infant was in a room by itself under entirely separate nursing care. Through prompt removal from the ward, two postoperative cases of hypertrophic pyloric stenosis were protected from infection. It is important to enumerate the facts concerning the babies who acquired the infection.

*Case 1* D, a girl, was admitted to the hospital November 10, 1937, when 1 month old, the birth weight had been 7 lb. One week previously she had been discharged from

a New York City hospital, where she had been exposed to a case of diarrhea. On admission she weighed 5 lb., 15 oz., she was vomiting and having frequent loose movements, and appeared extremely toxic.

*Case 2* P, a premature boy, was born outside the hospital and brought immediately to it, the birth weight had been 3 lb., 3 oz. At 1 month the weight had increased to 4 lb., 7 oz. The diarrhea started November 11. Several temperature reactions occurring previously were thought to be due to instability of his temperature-control mechanism.

*Case 3* G1, a girl, was one of twins born in the hospital, the birth weight had been 4 lb., 2 oz. This infant offered considerable difficulty in taking her feedings, and on the 20th postpartum day (November 11), when she began to vomit and have loose, green stools, she weighed 4 lb., 5 oz.

*Case 4* G2, a twin sister of Case 3, had weighed 4 lb., 4 oz., at birth. This infant also presented difficulty in feeding, and on the 21st postpartum day (November 12), when diarrhea began, she weighed 4 lb., 12 oz.

*Case 5* B, a boy, was born during the course of pneumonia of his mother, the birth weight had been 7 lb., 12 oz. When 1 week old, he was weaned and placed on a formula, at this time the weight was 6 lb., 14 oz. The following morning (November 16) six or eight loose, greenish yellow movements occurred.

*Case 6* F, a boy, was referred, when 6 days old, from an out-of-town hospital for correction of a complete cleft palate and left harelip, the birth weight had been about 6 lb. On admission his weight was 5 lb., 10 oz. Because of his handicap, considerable difficulty was experienced in feeding, and at the onset of the diarrhea on November 18, when he was 21 days old, he weighed 6 lb., 2 oz.

Table 1 presents a summary of the clinical experiences with these 6 infants in course of their infectious diarrhea.

The mortality of this series is extremely high, the highest, in fact, of any of the reported series of cases. However, it is not inconsistent with an infection which extracted a case mortality of 46 per cent from the average run of healthy newborn infants who acquired the disease. Five of the 6 babies who acquired the disease succumbed to it. As appears from the above description, it would be hard to select a group of babies constituting a less favorable risk than those who acquired this infection in our ward. The infants were all within the age period which appears peculiarly susceptible to this disease. Although born of a mother who went into labor and delivered during the active course of pneumonia, Case 5, the sole survivor,

## REPORT ON MEDICAL PROGRESS

## GENERAL ANESTHESIA\*

LINCOLN F. SISE, M.D.†

BOSTON

A SUFFICIENT period has now elapsed since the introduction, some five to ten years ago, of certain anesthetic agents for some crystallization of thought concerning their safety and usefulness. While in some cases a fair consensus has been arrived at, in others opinion is still sharply divided.

## VINYL ETHER

When vinyl ether was introduced some six years ago considerable difficulty in its use was experienced by many men. During induction there was considerable mucus and there were tremors and even convulsions. There was uncertainty about the drug's effect on the liver, owing to the demonstration of liver injury in experimental work on dogs under prolonged anesthesia. These various difficulties, however, are now rarely experienced. Possibly some of this change is due to the greater purity of the drug now produced. Goldschmidt, Ravdin and Lucké,<sup>5</sup> however, have shown that liver injury does not take place in the presence of abundant oxygen. This is simply another example of the damaging effect of anoxemia on the liver when toxic agents are being used and of the protective action of abundant oxygen, an action already frequently stressed by various investigators, but still occasionally ignored by many clinicians.

While general opinion is still somewhat divided on the use of this drug, it has on the whole had a favorable reception.<sup>1, 6, 9</sup> The facts that it is only very slightly irritating to inhale, that anesthesia may be induced with great rapidity, and that recovery is rapid and generally favorable, together with its small bulk, easy portability and the lack of necessity for bulky apparatus or equipment, make it very useful in a number of circumstances. It may readily be given with a simple open cone, and makes a pleasant, rapid and smooth induction for ordinary ethyl ether. It is applicable for short general anesthesia when relaxation is desired and for these operations and for ether induction is preferable to ethyl chloride because of its greater safety. While it lacks the dangerous vascular action of ethyl chloride, however, it resembles the

latter in being very rapid and powerful in its action, and consequently it should be used with great care.

## BARBITURATES

Opinion concerning the safety and use of the intravenous barbiturates is still divided, but they are being extensively used, and their employment seems to be increasing rather than diminishing. The increasing use in the operating room of electrical apparatus such as diathermy machines, which form potential ignition for inflammable anesthetics, together with some explosions of the latter, has focussed attention on this aspect of anesthesia and has emphasized the value of anesthetic agents such as the barbiturates, which are entirely free from danger of fire or explosion.

It is pointed out by those who oppose the use of these drugs that they resemble hypnotics rather than true anesthetics, and that the margin between the anesthetic and the lethal doses is comparatively narrow. This fact would tend to limit their use to operations which are either quite short or require only a light plane of anesthesia. It is also pointed out that their elimination is not so rapid as is that of the inhalation anesthetics. This is quite true if by the latter is meant the gas anesthetics such as nitrous oxide and cyclopropane. The difference in recovery time between ethyl ether and the intravenous barbiturates, however, is not great. Since they depend on the liver and kidneys for their detoxification and elimination they should not be used when there is severe disturbance of the function of these organs. There is a reasonable question whether elimination would not be greatly slowed up if shock should supervene.

Lundy has repeatedly pointed out that their use in children is inadvisable, but Hudson<sup>7</sup> has reported favorably on the use of Evipal in a series of 100 cases in infants and children.

With lethal doses, death takes place from respiratory rather than cardiac failure. This emphasizes the necessity for an experienced anesthetist and proper equipment for efficient artificial respiration, and again demonstrates the value of abundant oxygen, as well as the necessity for a competently functioning liver. Immediate depres-

†Senior anesthesiologist, Lahey Clinic.

of the amebas or bacteria commonly found in diarrhea could be discovered in these cases. In view of the highly infectious nature of this outbreak and the extremely mild pathologic findings, in striking contrast with the severe toxicity of the infection, we strongly favor a virus infection as the primary cause. Studies made of the throats of contacts of the babies and of their foods and various fomites were unproductive in revealing the cause or method of spread of the infection.

Accepting the contention that infectious diarrhea of the newborn, as reported by Rice and others, is a disease entity, we have every reason to believe that our cases were of the same nature. Both the clinical course and pathologic findings support this view. Moreover Case 1, which was admitted to the Pediatric Service with a diarrhea already well advanced and was undoubtedly the source of infection for the other infants, had been discharged only a few days previously from a New York hospital. The superintendent of this hospital stated that before the infant's discharge she was in a ward of the hospital in which there was a case of infectious diarrhea. Knowing the highly contagious nature of this infection, we are inclined to believe that our cases originated in this manner. It is interesting to note that since this outbreak we have had no similar cases in our hospital, nor have other cases been seen by me or any of my colleagues in this area. We believe that this is the first instance of this infection to be reported in New England. However, we have heard unofficially of one or two possibly similar outbreaks. We think it important to call attention to the highly contagious nature of this disease, as a warning should other outbreaks occur.

Although our therapeutic efforts were unsuccessful in all but one case, our negative observations may perhaps be of value. Periods of partial starvation with fluid administration by mouth in the form of tap water, cereal water or saccharin-sweetened tea were entirely unsuccessful in controlling either diarrhea or vomiting. Various feedings such as dilute evaporated or skimmed-milk mixtures, protein milk, a commercial pectin-agar preparation and raw scraped apple were all ineffectual in checking either diarrhea or vomiting. Reliance had to be placed on parenteral feedings to

keep the babies alive. An approach advocated by members of the house staff was accepted by the visiting staff only after other measures had failed to submit them to periods of complete starvation lasting from forty-eight to seventy-two hours. In view of the infants' condition this seemed a decidedly hazardous procedure, but in every case the diarrhea was checked. A recurrence demanded another period of starvation. This program was undoubtedly responsible for the recovery of Case 5. The stools in Case 6 became formed after two periods of starvation and remained formed up to the time of death, which was caused by pyogenic complications. This procedure is safe only when extremely vigorous measures of fluid administration are carried out. We came to the definite conclusion that an earlier use of this measure might have saved the lives of more of the babies. Following periods of starvation the use of protein milk in minute and increasing doses appeared to be the most successful method of feeding. In treating the severe abdominal distention relatively large doses of prostigmin proved of most aid.

#### SUMMARY

A disastrous outbreak of diarrhea on the Pediatric Service of the Worcester Memorial Hospital is reviewed. Nothing positive is known of the infecting organism and therefore of the method of the spread of the infection. Ordinary ward procedures, however, proved ineffectual in controlling the infection.

The need is emphasized of regarding diarrhea occurring in this susceptible age group with the utmost concern. The safety of other contacts demands that such cases be isolated, under the most careful aseptic, individual nursing care.

The clinical aspects of the outbreak are reviewed, and a picture of the relatively mild pathologic findings is given.

The value of periods of absolute starvation followed by gradually increased feedings of protein milk is emphasized.

The intratracheal method with this and with other agents is rapidly coming into more extended use and is now commonly employed at all well-equipped clinics

#### NITROUS OXIDE

This gas has been very widely held to be one of our safest general anesthetics, if not the safest. This view is to a very large extent justified because of the fact that the gas is of very low toxicity, and because it is eliminated with such extreme rapidity that resuscitation from overdosage is usually easy. However, it is such a weak anesthetic that if used without an adjuvant such as ether it has to be pushed very vigorously in order to obtain sufficient anesthesia. This cuts down the allowable oxygen to the point where there is but a very narrow margin between anesthesia and asphyxia, and considerable skill is therefore required to hold the patient within this range. While resuscitation is very rapid and effective if oxygen is given in time, collapse is equally rapid if it is not so given. Many anesthesiologists have felt that for this reason pure nitrous oxide and oxygen was not the superlatively safe anesthesia it was generally taken to be, and that it was frequently better to add some sort of adjuvant, usually ether, thus allowing more oxygen to be used.

Courville<sup>2</sup> was the first to crystallize thoughts that had been in the minds of many, by presenting postmortem proof of extensive brain injury in 13 fatal cases. His work has been confirmed by others,<sup>3</sup> and Courville<sup>4</sup> has now demonstrated that the cerebral lesions are due to asphyxia rather than to any toxic property of nitrous oxide itself. Stewart<sup>11</sup> again emphasizes these facts by reporting a case of cerebral necrosis and death following apnea during nitrous-oxide and oxygen

anesthesia. "Neurologic symptoms," he writes, "appeared within an hour and lasted about forty-eight hours, when coma supervened. Death from pneumonia occurred on the thirteenth postoperative day. A review of the literature shows that this is not a rare sequence of events."

\* \* \*

This report on progress in general anesthesia seems to resolve itself into a testimonial to the value of oxygen. Its action in protecting the liver has been shown with vinyl ether (as well as with chloroform and other toxic agents). It is of great value in anesthesia with the barbiturates (as well as with Avertin). It seems highly probable that the low clinical toxicity of cyclopropane is due in no small measure to the abundant oxygen ordinarily used with that drug. The harmful effects of lack of oxygen are shown with pure nitrous-oxide and oxygen anesthesia. Altogether, this emphasizes the fact that oxygen is a life-giving necessity, and that abundance of it in general terms means safety, and lack of it danger.

sive effects are proportional to the rate of administration rather than to the total dose

These drugs are being increasingly employed also as useful adjuncts to other forms of anesthesia. With local and regional anesthesia and with spinal anesthesia they are used by some for a quieting effect, sometimes without even the production of actual unconsciousness. Others employ them in combination with nitrous oxide to obtain a fireproof anesthesia of greater depth than seems advisable when either is used alone.

The two intravenous barbiturates most commonly used, the sodium salt of ethyl- (1-methyl-butyl) thiobarbituric acid (Pentothal Sodium) and the sodium salt of cyclo-hexenyl-N-methyl-barbituric acid (Evipal Soluble), while similar in many respects, are so different in many ways that in clinical use they may be regarded almost as complementary, rather than as interchangeable. Pentothal is powerful and depressing, and produces a smooth induction and good relaxation. Evipal is not so depressing, but induction is often marred by muscular tremor, and relaxation is apt to be poor. Pentothal is stated to produce liver necrosis in mice, while Evipal appears to be free from this hazard.<sup>10</sup> Further investigation of the action on the liver is now in progress, and while final results are not now available, it appears highly probable that when the liver is well supplied with glycogen and when there is no lack of oxygen during and following anesthesia, liver damage need not be feared. It is thus advisable to avoid any trace of anoxemia during the use of Pentothal as well as with other non-volatile general anesthetics.

The 10 per cent solution of these drugs which was at first recommended sometimes produced necrosis of tissue if accidentally deposited outside the vein. The 5 per cent solution now employed often causes a tender induration if spilled outside the vein, but does not ordinarily produce necrosis.

#### CYCLOPROPANE

Probably no other anesthetic has ever received such a widespread and enthusiastically favorable reception as has been that accorded this one. Since its introduction by Waters a voluminous literature has appeared which has given enthusiastic approval. Anesthetists everywhere have been most favorably impressed with its characteristics, such as very low toxicity and the large amount of oxygen which can be used with it. While comment is still very favorable it has become slightly tempered and is somewhat more discriminating. It is realized that no drug is perfect, and that this one is so powerful and depressing that untoward

and even alarming results may follow if it is given too rapidly or to too great a depth. To prevent these occurrences some clinics have adopted certain rules, such as that the rate of flow of the gas shall never exceed 500 cc per minute, or that the rate of cyclopropane flow shall never exceed that of oxygen.

Only one distinctly unfavorable report has appeared.<sup>2</sup> This records 4 cases of collapse under cyclopropane, with 2 deaths. One of these deaths, however, was largely due to other causes. The opinion is expressed that this present chapter of anesthetic history may be labeled "Cyclopropane. A surgical tragedy." This report, however, and this opinion stand alone. Nothing similar is recorded elsewhere.

At the Lahey Clinic we have had 3 deaths among 10,000 patients under cyclopropane anesthesia, 1 of them due to explosion.\* In order to see what the experience of others has been and to test present informed opinion, I have canvassed a number of the large users of cyclopropane. The replies indicate that they have used this anesthetic in 30,000 cases and have had 5 deaths attributable to the anesthetic. This, together with our experience, gives 40,000 cases and 8 deaths. If our death due to an explosion is eliminated, the mortality rate is found to be 1/5700. One of these users, who had done 5000 cases under cyclopropane without a death, stated that there had been 5 deaths under other anesthetics during the period when the former cases were being done. All these men still favor the use of cyclopropane, some of them quite enthusiastically.

The death from an explosion of this anesthetic, which recently occurred, has focussed attention on this aspect of the gas, and a meeting was held in Boston to formulate a general policy in regard to its use. It was attended by experts on electricity and explosives from the Massachusetts Institute of Technology and by surgeons, anesthetists, hospital executives and trustees of Greater Boston. After a free and thorough discussion bearing on all aspects of the explosiveness of cyclopropane and other anesthetics, it was decided to take no action looking to any curtailment of its use.<sup>†</sup>

At present, then, it is safe to say that experience with cyclopropane over the last five years has shown it to be a powerful drug which should be employed with great care and only by those well versed in its use, but that its properties in other respects are so valuable that informed opinion is now strongly favorable to its continued and rather extensive use.

\*The 2 occurring before the explosion were reported at the meeting of the Section of Anesthesia, Canadian Medical Association, Halifax, June 22, 1938.

†A summary of the discussion will be published shortly.

The intratracheal method with this and with other agents is rapidly coming into more extended use and is now commonly employed at all well-equipped clinics

#### NITROUS OXIDE

This gas has been very widely held to be one of our safest general anesthetics, if not the safest. This view is to a very large extent justified because of the fact that the gas is of very low toxicity, and because it is eliminated with such extreme rapidity that resuscitation from overdosage is usually easy. However, it is such a weak anesthetic that if used without an adjuvant such as ether it has to be pushed very vigorously in order to obtain sufficient anesthesia. This cuts down the allowable oxygen to the point where there is but a very narrow margin between anesthesia and asphyxia, and considerable skill is therefore required to hold the patient within this range. While resuscitation is very rapid and effective if oxygen is given in time, collapse is equally rapid if it is not so given. Many anesthesiologists have felt that for this reason pure nitrous oxide and oxygen was not the superlatively safe anesthesia it was generally taken to be, and that it was frequently better to add some sort of adjuvant, usually ether, thus allowing more oxygen to be used.

Courville<sup>2</sup> was the first to crystallize thoughts that had been in the minds of many, by presenting postmortem proof of extensive brain injury in 13 fatal cases. His work has been confirmed by others,<sup>8</sup> and Courville<sup>4</sup> has now demonstrated that the cerebral lesions are due to asphyxia rather than to any toxic property of nitrous oxide itself. Stewart<sup>11</sup> again emphasizes these facts by reporting a case of cerebral necrosis and death following apnea during nitrous-oxide and oxygen

anesthesia. "Neurologic symptoms," he writes, "appeared within an hour and lasted about forty-eight hours, when coma supervened. Death from pneumonia occurred on the thirteenth postoperative day. A review of the literature shows that this is not a rare sequence of events."

\* \* \*

This report on progress in general anesthesia seems to resolve itself into a testimonial to the value of oxygen. Its action in protecting the liver has been shown with vinyl ether (as well as with chloroform and other toxic agents). It is of great value in anesthesia with the barbiturates (as well as with Avertin). It seems highly probable that the low clinical toxicity of cyclopropane is due in no small measure to the abundant oxygen ordinarily used with that drug. The harmful effects of lack of oxygen are shown with pure nitrous-oxide and oxygen anesthesia. Altogether, this emphasizes the fact that oxygen is a life-giving necessity, and that abundance of it in general terms means safety, and lack of it danger.

## CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTEMORTEM AND POSTMORTEM RECORDS AS USED  
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT, M.D.

TRACY B. MALLORY, M.D., *Editor*

### CASE 25161

#### PRESENTATION OF CASE

*Third Admission* A fifty-eight-year-old freight clerk entered the hospital for repair of a right inguinal hernia. In his family history it was noted that his mother had died of arthritis and cardiovascular disease. This was the third admission for the patient, but the records for the two previous ones had been lost. No information could be obtained regarding the first admission, except that as a child he had had a periostitis of the tibia for about three months. At the second admission a posterior gastroenterostomy for duodenal ulcer was done. There was complete relief of symptoms thereafter.

The other item of interest in the past was a story of "inflammatory rheumatism," since his early thirties. Because of this condition he had been forced to stay out of work at least two or three weeks a year. The feet were usually affected, but in recent years he had complained of arthritis of the knees and hands. He was never permanently crippled. Two weeks before this admission he began to have another attack of "rheumatism" in his feet and knees and as he was unable to get about, he thought it a "good time" to have his rupture repaired.

Physical examination showed bilateral inguinal hernias and stiffness of both knees, with some limitation of extension. The right foot was swollen, and over the dorsum of the first metatarsal there was some tenderness. The blood pressure was 120 systolic, 75 diastolic. There was a soft systolic murmur at the apex, although the heart was not enlarged to percussion.

Examination of the urine showed a specific gravity which varied between 1.008 and 1.028. There was a very slight trace of albumin on three examinations. No casts or red cells were seen in the centrifuged specimen. The nonprotein nitrogen was 32 mg per 100 cc.

X-ray examination of the knee showed slight increase in the density of the bones with no change in the joint spaces. The elbow joints were normal.

A medical consultant noted that there was little in the way of deformity after twenty-five years

of rheumatic attacks. It was suggested that a search for foci of infection be made. Both hernias were repaired, and the only complications to his hospital stay were herpes simplex and retention of urine. During the study of his urinary retention he admitted having passed on many occasions a urine which on settling showed a brick-dust deposit in the bottom of the vessel.

*Fourth Admission* (five months later) Following an accident he had a dislocation of the semi-lunar bone of the right wrist and a fracture of the styloid process of the right radius.

*Fifth Admission* (four years later) The attacks of acute arthritis continued as before. Three weeks before this entry he began to have pain and tenderness in his left foot and ankle, and his local physician advised him to enter the hospital so that pus might be drained from this area.

Physical examination showed a moderately inflamed area 3 cm in diameter over the lateral surface of the fifth left metatarsal.

X-ray showed no evidence of osteomyelitis but some calcification of the blood vessels of the legs.

The tumor mass was removed surgically and on pathological examination showed chronic inflammation and uric acid deposits.

*Sixth Admission* (three years later) His "rheumatism" had progressed somewhat, and in addition to two or three acute attacks of arthritis each year, he had a great deal of stiffness of his joints all the time. Two weeks before admission he was forced to go to bed because of swelling of his right knee and dropsy of the right ankle.

Physical examination showed swelling and some tenderness of the knee, although there was no edema or joint effusion. There was some weakness of the right leg. The temperature, pulse and respirations were normal.

An orthopedic consultant examined the patient and expressed the opinion that the patient was suffering from rheumatoid arthritis.

Examination of the urine showed a specific gravity which did not exceed 1.014 at five examinations. A very slight trace of albumin was observed on one occasion. No casts or red cells were seen. A blood Hinton test was negative. The nonprotein nitrogen was 23 mg per 100 cc. Three blood uric acid determinations were 17 mg, 55 mg and 42 mg per 100 cc respectively. The basal metabolic rate was +13 per cent.

X-ray films of the spine showed no evidence of disease of the vertebral bodies but a localized process suggestive of trauma. There were proliferative changes about the knees and the ankles.

*Seventh to Tenth Admissions* (during the next

five years) During this time he was admitted three times to the hospital. On one occasion it was for a strangulated hernia, and the others for the treatment of his arthritis. At each admission it was felt that he was becoming progressively weaker and had more dyspnea on exertion. His activity was becoming progressively restricted. While he was being followed in the Out Patient Department for the distress in his feet, he was given foot pads and shoe supports, which appeared to make his feet worse and caused him to discard them.

The maximum specific gravity of his urine which was observed during this interval was 1.012. The urine contained some albumin but no casts and only rare red cells. Two years before his last admission x-ray films of the feet showed a marked narrowing of the joint spaces, with hypertrophic changes. No areas of destruction were seen. The knees showed changes which were thought to be characteristic of proliferative arthritis. X-ray films of the spine showed hypertrophic changes typical of the mixed form of arthritis.

One year before his last entry the patient spent the summer traveling to the West Coast and said that he had enjoyed the trips as much as he had when he had gone twenty years before.

*Tenth Admission* (one year later) He was admitted for a study of his kidney function and on this admission, inulin and creatinine clearance studies were done. An electrocardiogram taken at that time showed A-V and I-V block, indicative of widespread myocardial damage. Examination of his heart showed a rough systolic murmur heard all over the precordium. The blood pressure was 138 systolic, 78 diastolic.

*Final Admission* (two months later) He was admitted because of progressive shortness of breath and inability to care for himself at a friend's house where he had made his home. Examination showed no evidence of cardiac decompensation or pulmonary edema. The joints were essentially unchanged.

The electrocardiogram showed no change from the previous examination. The serum nonprotein nitrogen was 100 mg per 100 cc., the serum uric acid 138 mg. The total fixed base was 142 milliequivalents, the sodium, 132 milliequivalents, the carbon-dioxide combining power, 23 vol. per cent, the phosphate, 51 mg per 100 cc.

He became comatose shortly after admission. Two days later, without regaining consciousness, he developed hiccoughs and urea frost, and died following a terminal elevation of temperature to 104.8°F and of pulse rate to 160 per minute.

## DIFFERENTIAL DIAGNOSIS

DR ALFRED KRANES: It seems to me there are two questions to be answered in this case. What form of arthritis did the patient have? What type of renal disease? Before we discuss the arthritis, I think it might be interesting to point out one or two factors in this history. In the first place, it is interesting to note that his mother had died of the same disease or what appeared to be the same disease as the patient—some kind of joint disease and nephritis. Another interesting feature is that this patient had rheumatism for about forty years, and during that period he was apparently never very much crippled by it. It is stated that despite the long history of joint disease he got along fairly well. Another interesting point in the history is that his arthritis probably came in attacks, although the history is not very clear on that point. I am not sure just how long the attacks lasted, despite the statement that he was out of work two or three weeks each year because of them. It would also be of interest to know what precipitated the attacks, if anything did, and in addition whether he was perfectly free from any joint symptoms between acute attacks.

So far as the laboratory work goes, I get very little help there. The x-ray films are said to have shown hypertrophic changes, but at his age one would expect them. After all, he died at the age of seventy-two, and most of the studies were carried on in the last ten or twelve years of his life.

I should like to see the x-rays.

DR AUBREY O HAMPTON: These x-ray films are more interesting than the note would lead one to believe. I shall start on something I think I know a little about. The heart is enlarged, and the enlargement is left ventricular, with a tortuous aorta and calcification of the arch. There is also evidence of peripheral arteriosclerosis, which is seen even down to the terminal phalanges of the feet. When were these films taken?

DR KRANES: I believe in 1936. He was seventy years old then.

DR HAMPTON: The changes in the spine are those of the ankylosing type, with large spurs crossing the joints and with fairly normal joint spaces. This is not what one would expect with rheumatoid arthritis but rather the changes that go with the degenerative type. The lumbar spine shows practically nothing. The distribution of disease in the other joints is spotty. All the metatarsophalangeal and phalangeal joints are normal except for those of the first toes, while the tarsal joints are grossly abnormal. There are joint destruction and fusion in these tarsal joints, certainly

more marked lesions than degenerative arthritis would produce. The joint spaces are entirely absent, and it is an ankylosing type of arthritis. The great toes at the first metatarsophalangeal joints show punched-out areas of bone destruction that certainly simulate gout. There are smaller areas in the posterior joint margins of the ankle which go with gout. In this elbow there is calcification in soft tissue with swelling at one time, and calcification without swelling the next time. At no time is there as much atrophy in the bones as one would expect. From the x-ray appearance he did not have a persistent arthritis. He used his joints between attacks.

DR KRANES. Apparently there is a good deal more in the x-ray films than in the written report. I do not believe that we have to consider many forms of arthritis very seriously. In fact there is only one that need be considered at all, namely gout. I just cannot see how any other form of arthritis could give this history plus the x-ray findings. To be sure he probably did have a lot of degenerative arthritis, but you would expect it in any man of seventy-two, regardless of what other disease he might have. Rheumatoid arthritis is extremely unlikely with a history of this type and with these x-ray pictures. After forty years of rheumatoid arthritis, coming in attacks which were apparently quite severe, one would expect much more crippling or disability and a lot more in the way of x-ray changes in other joints. Other types of specific infectious arthritis, such as gonococcal, tuberculous and syphilitic, must be mentioned, merely to exclude. They are extremely unlikely, as is rheumatic fever. I do not think we have to consider anything aside from gout.

In favor of gout is the family history of joint disease which occurs in a very high percentage of patients with gout. The harder you look for it the more often you find it. The patient's history of acute attacks that subsided and left him relatively free between attacks is also quite characteristic. There is probably some increase of urate excretion in the urine, qualitative to be sure. The statement about brick-dust deposits in the urine probably represents precipitated urates, and patients with gout have larger urate excretions than do normal people. Finally there is the episode of an apparently septic joint. Acute gouty joints frequently resemble septic joints and are operated on with the idea that pus will be obtained. In this case uric acid deposits were found, which clinch the diagnosis.

There are nevertheless a few disturbing factors so far as the diagnosis of gout goes. First are the

repeatedly normal uric acid determinations on his blood, except for the terminal one of 13.8 mg per 100 cc., which, since the patient was in uremia, is of no diagnostic value. So far as I know, no cases of gout have been encountered in this hospital with a normal amount of uric acid in the serum. Other people working in this field disagree and claim that normal uric acid values occur in many gouty individuals. Dr Talbott does not believe that and I would like to have him say a few words if this patient proves to have gout. In this connection it occurs to me that this patient had been studied over a long period of time and perhaps most of the uric acid determinations had been done by the old method. A second disturbing feature is that after forty years of gout he had developed no tophi. Thirdly, after two operations he developed no acute arthritis. Gouty attacks frequently occur after trauma and after an operation, however, this patient had two operations with no flare-up of his joint symptoms.

So far as his renal disease goes, I think it is always a guess to try to predict what type the patient has. In this patient, our first indication that he had any renal impairment occurred during his sixth admission at the age of sixty-five when it was found that his specific gravity did not go above 1.014. From that time until his death there was a slow progression of renal failure. The results of the clearance tests are not given, but I presume they were quite low, since he died two months later in uremia. I do not believe that this patient could have had glomerulonephritis at his age, at least there is no evidence of glomerular damage or of acute nephritis in the history. He was followed for a long period when his renal function was apparently normal. He was at the age of course when he might have had prostatic obstruction. However, there is no history suggesting it, and no mention on physical examination about the size of the prostate. People with gout frequently have uric acid stones. This patient had no history of having had attacks of renal colic. It is conceivable that he may have had silent stones blocking off one or both ureters and causing hydronephrosis. In the absence of direct evidence we have no right to make that diagnosis.

DR HAMPTON. He had a perfectly negative intravenous pyelogram in 1936. The kidney pelvis were large, but the calices were not dilated and he functioned fairly well.

DR KRANES. That is interesting because according to the renal function tests done before 1936 he showed impairment of concentrating power.

How about a gouty nephritis? It is well known

that a very high percentage of people with gout develop renal insufficiency, but there is not so much agreement as to the type of renal lesion that occurs. Various authors describe different types. The most consistent lesion is a vascular type of nephritis. A patient of this age with longstanding gout and evidence of arteriosclerosis throughout his body undoubtedly has a high degree of vascular nephritis. It is queer that he did not have a higher blood pressure with a diffuse vascular nephritis. There is another type of renal lesion described in gout where deposits of urates occur in the renal tubules, causing a type of renal insufficiency similar, I suppose, to the Bence-Jones kidneys of myeloma, the kidneys becoming plugged with urates. There have been a few cases described in which these urate deposits have been primarily responsible for the renal failure. I wonder if this patient, with a normal blood pressure, did not have an extensive degree of this type of nephritis. He also had a severe degree of coronary arteriosclerosis, as shown by the electrocardiogram and by the enlargement of the heart without hypertension. So I shall summarize by saying that this patient had gouty arthritis, had probably a combination of vascular and gouty nephritis, whatever that is, had severe coronary disease and probably some terminal infection such as pneumonia, having died in uremia there is a strong possibility that he may have had terminal pericarditis.

DR. JOHN TALBOTT: Dr. Kranes is perfectly right in assuming that the earlier uric acids were done on whole blood. It is not unusual to find normal whole-blood uric acid, which if repeated on serum is elevated. There was one determination on whole blood (5.2 mg) which is above the normal range. The level for serum uric acid of patients with gout is 60 mg per 100 cc. or more.

So far as the x-ray films are concerned, in many cases we have given up trying to confirm a diagnosis of acute gouty arthritis by x-ray examination. I think this is a good example. The most we can say is that the changes are rather consistent with gouty arthritis and the fact that he had had his symptoms some forty years and did not have a characteristic picture does not mitigate against the diagnosis. The clinical appearance of his hands was that of advanced hypertrophic arthritis, as opposed to gouty arthritis with subcutaneous tophi that are characteristic. He had two tophi on his feet, however, which were removed surgically. The pathological report showed urate crystals. His kidney function by inulin clearance was only one-third normal. We believed that the course of the changes in the kidneys was consistent with gout. He had evidence

of renal insufficiency in one form or another, without developing terminal failure except the last few days.

DR. HAMPTON: How often do you see ankylosis in gout?

DR. TALBOTT: In about 20 per cent of our patients.

DR. HAMPTON: That is the thing that disturbed the X-ray Department. I do not remember ever having seen complete ankylosis of multiple joints as seen here in both tarsal areas. It upset me no end.

DR. TALBOTT: We have several patients that show it.

#### CLINICAL DIAGNOSES

Gout  
Coronary heart disease

#### DR. KRANES'S DIAGNOSES

Gout  
Vascular and gouty nephritis  
Generalized arteriosclerosis  
Terminal infection (? pneumonia, ? pericarditis)

#### ANATOMICAL DIAGNOSES

Gout  
Hypertrophic (degenerative) arthritis of the spine  
Urate deposits in kidney  
Healed pyelonephritis, left kidney  
Chronic vascular nephritis  
Amyloidosis of kidneys and adrenal glands  
Cardiac hypertrophy  
Arteriosclerosis, coronary, aortic and renal  
Lobar pneumonia, right lower lobe

#### PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: At the postmortem examination all the joints examined, and they were many, showed extensive urate deposits—an extremely characteristic picture of gout. There was also hypertrophic arthritis of the spine. The remaining findings were a terminal pneumonia, a considerably hypertrophied heart, fibrotic and calcified but not particularly narrowed coronary arteries, and a pair of kidneys of which the left one weighed only 75 gm and the right 275 gm. The left kidney was very characteristic of a healed pyelonephritis. The other kidney showed a combination of lesions. There were extensive deposits of urates in the pyramids. There were fairly marked blood-vessel changes. There was also a very considerable amyloid deposit. Histologically the adrenal glands also showed moderate amyloid disease. To which of all the multiple factors the renal insufficiency was due, I do not know, prob-

ably to a combination of all three. One might speculate that the adrenal involvement had prevented the development of hypertension, in view of recent work on adrenalectomy in Goldblatt dogs

## CASE 25162

### PRESENTATION OF CASE

A thirty-seven-year-old married woman was admitted complaining of swelling of the abdomen.

Two and a half years before admission the patient had been delivered normally of her fourth baby. Following this she had sacroiliac pain. A corset and a reducing diet were prescribed, but about three or four months later she began to eat freely again. During the next two years she gained weight progressively but noted no essential abnormality until two months before admission. During the two months preceding entry her abdomen became unusually large and was thought to be abnormally hard, particularly on the left side. A mass seemed to occupy the entire lower abdomen and extended into the left upper quadrant. She noticed a sense of pressure within the abdomen, but there was no pain except for a transient stinging sensation just below the left costal margin. Her menstrual cycle had remained normal, and there were no urinary complaints. There had been slight gaseous distention and increasing fatigability. Bowel movements were normal.

Physical examination showed a fairly obese woman with slight pallor. Examination of the head and chest was negative. The blood pressure was 125 systolic, 85 diastolic. Occupying the entire left side of the abdomen was a large, rounded, non-tender, questionably cystic tumor, which was not movable. It was thought that a lower border could be palpated above the brim of the pelvis. It was seemingly, though not definitely, continuous with a similar mass in the right lower quadrant. No further details were recorded. By vaginal examination the mass could not be palpated. The cervix was slightly eroded but in normal position, and the uterus was normally mobile.

The temperature was 99°F, the pulse 60, and the respirations 20.

The urine examination showed a specific gravity of 1.020, a large trace of albumin and a rare white cell. A phenolsulfonephthalein kidney-function test showed 50 per cent excretion in two hours. The blood showed a red-cell count of 4,570,000 with 80 per cent hemoglobin, and a white-cell count of 7300 with 60 per cent polymorphonuclears. The nonprotein nitrogen of the serum was

23 mg per 100 cc. A blood Hinton test was negative.

A plain x-ray film of the abdomen showed a large, dense, smooth, rounded mass filling the entire left side of the abdomen and extending anteriorly across the midline in the lower abdomen. There were two 15-cm flecky areas of calcified density in the right upper quadrant, but no areas of calcification in the mass. All the intestinal shadows lay in the right upper abdomen. An intravenous pyelogram showed a normal right kidney. The films did not show sufficient penetration to visualize the left kidney. There was a pressure defect on the fundic portion of the bladder, which was more marked on the right side. A barium enema showed no evidence of abnormality within the colon. The sigmoid was displaced to the right of the midline, and at the level of the sacroiliac joint there was a pressure defect suggestive of external pressure. The descending colon was displaced anteriorly and medially. On these films the left kidney shadow was sharply outlined and was not displaced, the renal pelvis and ureter were grossly dilated, and the ureter appeared to be compressed at the level of the second lumbar vertebra.

On the fifth hospital day an operation was performed.

### DIFFERENTIAL DIAGNOSIS

DR FRANKLIN G. BALCH, Jr. In going over the history, I cannot get much enlightenment as to the diagnosis. We have a thirty-seven-year-old woman who had gained considerable weight, particularly in the last two months. Physical examination showed that she was fairly obese and well-nourished and that there was a large mass on the left side, as described. The laboratory findings do not contribute much. She had a large trace of albumin in the urine which can be explained by damage to the left kidney. The x-ray films seem to be the most important things in reaching a diagnosis. I wonder if we can see them now.

DR GEORGE W. HOLMES. One notices first a mass in the flank which is displacing the bowel toward the right. Apparently it is not connected with the gastrointestinal tract. I should suspect that the question was to decide whether it was retroperitoneal or in the peritoneal cavity.

DR BALCH. Can you make out any definite borders?

DR HOLMES. No.

DR BALCH. Is that some of the dye retained from the previous intravenous pyelogram?

DR HOLMES. This film must have been taken

on the same day that the dye was given and rules out the kidney as the source of the tumor. The kidney is displaced somewhat toward the spine and upward. The tumor would be retroperitoneal if my interpretation is correct. I am not quite certain how much the kidney is displaced because the film was taken with the patient lying face down. I think we can say that the tumor is not in the gastrointestinal or the urinary tract and that in all probability it is retroperitoneal. There is nothing in the chest.

DR. BALCH: That helps a good deal in the diagnosis. When I first read over this case, I thought of the possibility of ovarian cyst, but on further consideration, it did not seem to fit in with ovarian cyst because, as Dr. Holmes has pointed out, the colon is displaced medially. I do not believe that even a large ovarian cyst could do that. Also, this tumor could not be felt on vaginal examination, and we should expect to be able to palpate an ovarian cyst by this method. Fibroids are ruled out by the physical examination. Another possibility of intraperitoneal tumor is mesenteric cyst, which is a rare finding and is usually freely movable, therefore we can rule that out. Splenomegaly can be ruled out by the x-ray films and the lack of other findings. So that leaves us with retroperitoneal tumors to consider.

Malignant kidney tumors, such as hypernephroma and carcinoma, I believe we can rule out by the x-ray findings. Polycystic kidneys are usually bilateral, and the x-ray films do not suggest these lesions. A diagnosis of a single solitary cyst of the kidney does not fit. Extensive hydronephrosis is ruled out by the x-rays, even though there is evidence of a hydronephrosis. Retroperitoneal and intraperitoneal echinococcus cysts have been reported, but there is nothing here that would make us consider such a diagnosis. Therefore, we are left, it seems to me, with the diagnosis of a retroperitoneal sarcoma or, more likely, a retroperitoneal lipoma. With a retroperitoneal sarcoma of this size the patient should show a good deal more emaciation than she did and an advanced state of cachexia. It seems to me that limits our diagnosis pretty much to retroperitoneal lipoma. These are known to be slowly growing and frequently asymmetrical. They have been reported as weighing as much as 60 or 70 pounds and usually start in the perirenal fat.

DR. HOLMES: May I interrupt to say that the x-ray picture is not one of lipoma.

DR. BALCH: That disturbs me. However, I still believe that it is a retroperitoneal tumor and not an intra-abdominal tumor. In spite of the x-ray findings I cannot figure out any other retroperitoneal tumor that would seem to fit this picture.

so I shall stick to my diagnosis of retroperitoneal lipoma.

DR. TRACY B. MALLORY: Would anyone else like to hazard a diagnosis?

DR. AUGUSTUS S. ROSE: Was it definite that there was a second tumor in the right lower quadrant?

DR. MALLORY: That was not confirmed later.

DR. GEORGE A. LELAND: In addition to the x-ray report that was available when this patient was on the service last summer, I had the advantage of Dr. George G. Smith's examination, which is not recorded for Dr. Balch. I think what he said is of interest. The note is as follows: "The hydronephrosis on the left is probably due to pressure on the ureter by the cyst. This suggests retroperitoneal origin for the cyst. The right kidney seems normal. I do not believe there is anything about the kidney condition to indicate removal of the cyst."

In other words, those who had an opportunity to examine the patient were quite certain that there was a cyst. The protocol said that there was a questionable cystic tumor, that was misleading. The members of the X-ray Department likewise ventured into the realm of possibilities, they mentioned in their original report that "the difference in densities suggests lipoma or cyst." On account of the density of the mass, the possibility of sebaceous material was also mentioned somewhere in the history. So preoperatively we committed ourselves to a diagnosis of retroperitoneal cyst of the dermoid type. We thought that there might possibly be a developmental rest somewhere in this region.

I shall read my operative note.

A 10- to 12-cm. incision was made through the left rectus muscle, the major portion of the incision being above the level of the umbilicus. Exploration with the examining hand disclosed a large lobulated cyst which was retroperitoneal. It had displaced the descending colon toward the midline. The uterus could be identified. The right ovary was normal in size and shape, the left ovary was elongated. The liver appeared to be normal. There was nothing abnormal in the peritoneal cavity to suggest malignant disease. A puncture wound was made in the cyst, and approximately 5500 cc. of clear serous fluid was aspirated with the suction apparatus. After this had been removed the anesthetist reported that the patient's pulse had gone up very rapidly; the suction apparatus was therefore removed. The opening was closed with interrupted catgut sutures. The peritoneum overlying the cyst was then divided, and the cyst was freed, chiefly by manual blunt dissection from the descending colon and the region of the kidney. The kidney was visualized. Gradually the entire cyst was brought out through the opening and freed of its attachments. Altogether perhaps six or seven veins, none of which were over 2 mm. in diameter, were clamped. There was no main blood supply. After the cyst had been

delivered it was apparent it had no connection whatsoever with the ovary or parovarian structures. The peritoneum of the posterior wall was then brought together, and the wound was closed in layers, in the usual fashion. Evacuation of the contents of the cyst remaining after the cyst had been removed yielded about 2800 cc. Since a certain loss of fluid was inevitable when the stab wound was made, the cyst must have contained very close to 8000 cc. of fluid. On opening the cyst in the operating room there were two areas which resembled white coral, these areas were not hard.

The patient's convalescence was quite satisfactory.

#### CLINICAL DIAGNOSIS

Retroperitoneal dermoid cyst

#### DR. BALCH'S DIAGNOSIS

Retroperitoneal lipoma

#### ANATOMICAL DIAGNOSIS

Retroperitoneal papillary adenocystoma

#### PATHOLOGICAL DISCUSSION

DR. MALLORY The specimen that reached us was indistinguishable from an ordinary papillary cystoma of the ovary. It was lined with an epithelial layer, and there were short, densely fibrous papillary projections into the cyst. If I had not had Dr. Leland's word that the left ovary was found, I would have assumed, without question, it was an ovarian cyst. I do not know what its origin may have been unless some remnant of ovarian tissue had been left there in the course of the descent of the ovary. I cannot remember

ever having seen this type of cyst in retroperitoneal tissue, in fact anywhere except in the ovary.

The patient had an interesting aftermath that might be brought up. A few months after operation a tumor of about half the size of the original cyst developed in the same location, this was very suggestive of a recurrence and caused a great deal of diagnostic difficulty. Dr. Holmes, have you anything to say on that?

DR. HOLMES The mass is about the same density as that of the previous tumor. From the x-rays one is not justified in saying just what the character of the mass is. All we can say is that there is a small mass which has recurred in the same region.

I should like to point out that if it had been a fatty tumor it would have been of about the same density as air in the abdomen. Dr. Leland's statement was interesting, we are apparently growing up.

DR. MALLORY After numerous examinations the patient was re-admitted and re-explored, and a cystic mass again found in approximately the same area. A section through the wall showed a hematoma with organization, so that it was not a recurrence.

DR. BALCH The record stated that the large mass of the original tumor was continuous with a small mass on the right. Did you find any such mass?

DR. LELAND As I recall it there was a sort of lobulation that went across the midline.

## CHIROPRACTIC AGAIN

THE report of the Special Commission on Osteopathy, Chiropractic, Food, Drugs and Poisons has been filed as House Bill 2151. Among other objects, the "commission was created for the purpose of making an investigation relative to establishing a board of examination and registration in osteopathy, and regulating the practice of osteopathy, [and] relative to establishing a board of registration of chiropractors, and regulating the practice of chiropractic." The commission recommends that in the case of osteopathy no legislation is necessary, but that in the case of chiropractic a board of registration should be established, "but with very strict regulations." Three matters deserve discussion: the disposition of the problem presented by the petitions of osteopathic physicians, the reason why osteopathy and chiropractic

did not receive the same treatment by the commission, and the "very strict regulations" for chiropractic set forth in the bill.

Concerning osteopathy, the report reads "After several hearings the commission is not convinced that the Commonwealth should establish a separate board of examination and registration of osteopaths. It has been asserted, and admitted, that osteopaths engage in the practice of medicine, therefore it appears to the commission that they should be required to pass the examination of the Board of Registration in Medicine." The premises are sound, in logic, there is no escape from the conclusion.

Why does not the same argument apply to chiropractic? It has been asserted, and admitted, that chiropractors engage in the practice of medicine. Furthermore, the report reads "Evidence was presented to the commission that there are many chiropractors illegally practicing in Massachusetts today, many of them being incompetent. For this reason we feel that a board of registration should be established." "Practicing" would seem to constitute the practice of medicine—an opinion upheld by the Supreme Judicial Court of Massachusetts in the Zimmerman case. If this be so, why should there be any discrimination between the statutory regulation of osteopathic practice and that of the chiropractors? Is it a good policy to legislate according to the dictum that the more illegal and incompetent practitioners there are, the greater is the need for lower standards of practice?

Restriction of space prevents discussion of all the details of the bill, but a critical point is found in Section 87F, defining chiropractic. "Chiropractic, or the system, method or science commonly known as chiropractic, or the practice of chiropractic, is hereby defined to be the science of palpating and adjusting the articulations of the human spinal column. This definition is inclusive, and any and all other methods are hereby declared to be not chiropractic." This is jargon triumphant. "Practice" or doing is defined as "science" or knowing. Furthermore, "the very strict regulations" appear to be unenforceable.

delivered it was apparent it had no connection whatsoever with the ovary or parovarian structures. The peritoneum of the posterior wall was then brought together, and the wound was closed in layers, in the usual fashion. Evacuation of the contents of the cyst remaining after the cyst had been removed yielded about 2800 cc. Since a certain loss of fluid was inevitable when the stab wound was made, the cyst must have contained very close to 8000 cc of fluid. On opening the cyst in the operating room there were two areas which resembled white coral, these areas were not hard.

The patient's convalescence was quite satisfactory

#### CLINICAL DIAGNOSIS

Retroperitoneal dermoid cyst

DR. BALCH'S DIAGNOSIS

Retroperitoneal lipoma

#### ANATOMICAL DIAGNOSIS

Retroperitoneal papillary adenocystoma

#### PATHOLOGICAL DISCUSSION

DR. MALLORY The specimen that reached us was indistinguishable from an ordinary papillary cystoma of the ovary. It was lined with an epithelial layer, and there were short, densely fibrous papillary projections into the cyst. If I had not had Dr. Leland's word that the left ovary was found, I would have assumed, without question, it was an ovarian cyst. I do not know what its origin may have been unless some remnant of ovarian tissue had been left there in the course of the descent of the ovary. I cannot remember

ever having seen this type of cyst in retroperitoneal tissue, in fact anywhere except in the ovary.

The patient had an interesting aftermath that might be brought up. A few months after operation a tumor of about half the size of the original cyst developed in the same location, this was very suggestive of a recurrence and caused a great deal of diagnostic difficulty. Dr. Holmes, have you anything to say on that?

DR. HOLMES The mass is about the same density as that of the previous tumor. From the x-rays one is not justified in saying just what the character of the mass is. All we can say is that there is a small mass which has recurred in the same region.

I should like to point out that if it had been a fatty tumor it would have been of about the same density as air in the abdomen. Dr. Leland's statement was interesting, we are apparently growing up.

DR. MALLORY After numerous examinations the patient was re-admitted and re-explored, and a cystic mass again found in approximately the same area. A section through the wall showed a hematoma with organization, so that it was not a recurrence.

DR. BALCH The record stated that the large mass of the original tumor was continuous with a small mass on the right. Did you find any such mass?

DR. LELAND As I recall it there was a sort of lobulation that went across the midline.

tient had undergone an appendectomy at twelve years of age and had had measles and mumps when she was twenty-three. Catamenia began at eleven, were regular with a twenty-eight-day cycle and lasted six days. She usually flowed profusely and with a great deal of pain on the first day. Her last period was November 26, 1921, making her due for delivery September 2. Her previous pregnancies had resulted in a normal delivery at term and a miscarriage at six weeks. The present pregnancy had been normal throughout.

When seen at home, the uterus was the size of a full-term uterus, the fetal heart was distinctly heard, and the vertex was presenting in the OLA position. The uterus was contracting every five or six minutes and relaxing well between pains. Labor had begun indefinitely at 5 p. m. A vaginal examination at 1 a. m. on September 11, showed the cervix more than half dilated, with intact membranes. The membranes were ruptured artificially, and the progress of labor became rapid. The baby was born shortly after 2 a. m. There was a median tear of the perineum at the site of a previous laceration. As soon as the baby was born, there was a large amount of fresh bleeding which showed that the placenta had separated. With each contraction, blood gushed from the vagina. Because of this, the placenta was immediately delivered by the Credé method. It came away intact, but the membranes were not complete. There was so much bleeding at the time that the perineum was not sewed up. Posterior pituitary extract, ergot and morphine were immediately administered, and a firm uterine contraction occurred, however, the patient went into profound shock. She perspired freely, was very white and asked for water. Her blood pressure was 80 systolic, 60 diastolic. She was given a quart of water by rectum, which was not retained. Heaters and blankets were applied, and the foot of the bed was elevated. There was no further bleeding. Her condition gradually improved, and at 7.30 a. m. she was in good condition with a pulse of 100 and with much improved color. Her subsequent convalescence was uneventful save for a mild sapremia due to retained membranes.

*Comment* This case is recorded because of the difficulties attendant upon home deliveries twenty years ago. The bleeding undoubtedly occurred because the placenta separated immediately and was not spontaneously delivered. Even today such cases of profuse hemorrhage can hardly have the benefit of transfusion or the advantage of intravenous medication. Had this patient continued to bleed the uterus undoubtedly would have been packed. Fortunately, added hemorrhage was not encountered, the uterus shut down adequately, and like

most cases of shock alone, recovery was spontaneous.

Those of us who now do all our obstetrics in the hospital where modern facilities are available and where there are always plenty of hands to help cannot appreciate the difficulties and embarrassments of complicated home deliveries unless we are old enough to remember them. Undoubtedly, there are patients each year in Massachusetts who, confined at home, die of postpartum hemorrhage simply because the facilities of the modern hospital are not available. Some of the complications of obstetrics can be prepared for beforehand. Postpartum hemorrhage from uterine atony cannot be anticipated, and it is certainly not at all feasible to have the home equipped to meet this emergency, in consequence, hospitalization should be entertained whenever possible.

### LEGISLATIVE NOTE

The chiropractic bill, now before the Committee on Public Health, has been given a number, House Bill 2151.

The people who favor this bill have been particularly active this year, and we strongly urge each member of the Society to write to his senator, his representative and members of the Committee on Public Health asking them to oppose it. The hearing will be held at 10.30 a. m., April 25, in the Gardner Auditorium. BE SURE TO COME, AND BRING YOUR FRIENDS!

CHARLES C. LUND, *Chairman*  
Committee on State and  
National Legislation

### MEDICAL POSTGRADUATE EXTENSION COURSES

The following sessions, given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau, have been arranged for the week beginning April 24.

#### BERKSHIRE

Thursday, April 27, at 4.30 p. m., at the House of Mercy Hospital, Pittsfield. Subject—The Control and Treatment of Respiratory Infections. (This is to include the serological treatment of pneumonia in infants and children.) Instructor John A. V. Davies. Melvin H. Walker, Jr., *Chairman*.

#### FRANKLIN

Wednesday, April 26 at 8.00 p. m., at the Franklin County Public Hospital, Greenfield. Subject—Gonorrhea. Modern treatment of gonorrhea. Instructor Sylvester B. Kelley. Halbert G. Stetson, *Chairman*.

In spite of the strong arguments in the minority report on chiropractic, it remains the report of a minority, and as such, carries less weight, although the commission was unanimous against a separate board for osteopathy. The lesson to be learned from this report is that physicians must ever be alert to detect efforts to lower the standards for the practice of medicine and must constantly exert themselves to prevent such degradation.

## ILLUSION AND SCIENCE

MODERN science is characterized by a quality shown in William Harvey's investigations which led to his discovery of the circulation of the blood. He asked a critical question, *How much* blood is thrown out of the heart at each contraction? Today science asks insistently these questions: How many? How much? Mathematics, although it cannot be comprehended within the designation of the science of quantity, has served as an effective model for the approximately precise sciences of inanimate nature. It presents an ideal which the sciences of animate nature strive to realize. As some of the words or formulas are transferred to the social sciences, there is created an illusion of attainable exactitude and precision, dangerous because it is so far from actual knowledge.

A recent paper by Mr. Michael M. Davis,\* entitled "Nursing Service Measured by Social Needs," is an example of this illusion, widespread in many social studies. The limitations of the value of statistics are well known to the expert and it is the disregard of these limitations which has led to the characterization of statistics as untruth of superlative degree. *Corruptio optimi pessimum*.

The purpose of the study was to obtain exact information concerning nursing service and methods of determining its quantitative and qualitative adequacy. This is indeed a social need. The writer uses the expression "yardsticks of both quantity and quality," and an example of the reasoning which leads to the "therefore" of his conclusions is given by the following quotation, in which the words in brackets are our own. It is a piece

of reasoning invalidated by a premise which is admitted early and then treated as if it did not exist. "If we make an estimate of the amount of nursing care actually furnished, we do not find a reliable body of data [in logic the argument must stop if no reliable data are available, but not so in social science], but roughly from the known amount of unemployment of nurses in private duty and the amount of work done by salaried visiting nurses, it may be [unreliably] estimated that about one-fifth day's nursing care per capita of our population is now supplied the people of the United States outside of hospitals. If this figure is reliable [which it is not, *ex hypothesi*], the amount of nursing now supplied outside of hospitals is about 40 per cent of the amount needed. If we had for each state and for many local communities such [unreliable] yardsticks of public need as compared with services rendered, we should be much farther along in judging what should be done, and where and how."

It is unfortunate that a plea for more science should be supported by unscientific argument. This kind of reasoning is indeed the strongest plea, unconscious perhaps on the part of the writer, for release from illusion and a return to the sanity which the word yardstick denotes but does not make real. Whatever other social needs there may be, one fundamental urgent need is restraint within the confines of logical discourse in dealing with our vital problems.

## DEATHS

HART—CLARENCE D. HART, M.D., of Somerville, died April 9 in Savannah, Georgia. He was in his forty fifth year.

Dr Hart received his degree from the Albany Medical College, New York, in 1931, and also attended Harvard Medical School. He had specialized in public health and had recently been appointed to serve as health officer of Savannah.

Dr Hart was a member of the Massachusetts Medical Society and the American Medical Association.  
 His father survives him.

LYNCH—CHARLES E. LYNCH, M.D., of Quincy, died April 13. He was in his forty second year.

Born in South Boston he received his degree from Tufts College Medical School in 1923. He was a member of the Massachusetts Medical Society and the American Medical Association.

His widow, a son, a daughter, four sisters and a brother, Dr James Lynch, survive him.

#### DEATHS

HART — CLARENCE D. HART, M.D., of Somerville, died April 9 in Savannah, Georgia. He was in his forty fifth year.

Dr. Hart received his degree from the Albany Medical College, New York, in 1931, and also attended Harvard Medical School. He had specialized in public health and had recently been appointed to serve as health officer of Savannah.

Dr. Hart was a member of the Massachusetts Medical Society and the American Medical Association.  
His father survives him.

LYNCH — CHARLES E. LYNCH, M.D., of Quincy, died April 13. He was in his forty second year.

Born in South Boston he received his degree from Tufts College Medical School in 1923. He was a member of the Massachusetts Medical Society and the American Medical Association.

His widow, a son, a daughter, four sisters and a brother, Dr. James Lynch, survive him.

*Paratyphoid B fever* was reported from Brookline, 1, West Springfield, 1, total, 2

*Pellagra* was reported from Westminster, 1, total, 1  
*Pfeiffer bacillus meningitis* was reported from Greenfield, 1, Lowell, 1, Springfield, 1, total, 3

*Septic sore throat* was reported from Boston, 5, Chelsea, 1, Fall River, 2, Frammingham, 1, Greenfield, 1, Lawrence, 1, Lowell, 1, Lynn, 1, Malden, 2, New Bedford, 2, Quincy, 1, Somerville, 1, Woburn, 2, total, 21

*Trichinosis* was reported from Boston, 1, Springfield, 1, total, 2

*Typhoid fever* was reported from Boston, 1, Brookline, 1, Everett, 1, Lynn, 1, Plymouth, 1, total, 5

*Undulant fever* was reported from Andover, 1, Barnstable, 1, total, 2

Whooping cough, measles, chickenpox, and paratyphoid B fever were reported above the five-year average.

Scarlet fever, diphtheria, mumps and German measles were reported below the five year average.

Tuberculosis (other forms) showed record low figures for the second consecutive month.

Lobar pneumonia, meningococcus meningitis and pulmonary tuberculosis were reported below the five year average.

Typhoid fever and undulant fever were reported at figures equal to that of the five year average.

Animal rabies showed record low incidence for the third consecutive month. A new focus was noted in Woburn

## MAINE NEWS

### THE WOMEN'S FIELD ARMY

Plans for the 1939 campaign of the Women's Field Army of Maine are being completed under the direction of the Volunteer Campaign Committee consisting of Mr Samuel Stewart, of Lewiston, chairman, Mrs. John H. Huddleston, of Orono, Mrs. William Holt, of Portland, Dr Frederick T Hill, of Waterville, and Dr Edward H. Risley, of Waterville, chairman of the Advisory Board, *ex officio*

April has been designated as Cancer-Control Month by the American Society for the Control of Cancer. The intensive campaign will be carried on in most communities in Maine during the week of April 3, although the entire month will be given over to the work for the benefit of those groups which cannot carry on their campaign during the first week. Continuing the fine co-operation of the medical profession with the Women's Field Army, ninety-eight physicians, representing all counties of the State, have accepted chairmanships of advisory boards in their various sections.

Figures compiled at headquarters show the scope of the service given in 1938 through the Dr Joseph W Scannell Memorial Fund. Every county is represented by patients treated from May to October, 1938, when, because of the increasing demand for free treatment, the funds became exhausted. As Maine has no hospital for the free treatment of the indigent cancer patient, this service of the Women's Field Army has been a great boon to the 194 needy patients treated by either radium or x rays

### POSTGRADUATE EDUCATION

The Committee on Graduate Education has prepared the following panel discussions which are now available for county medical society meetings

Pneumonia—Dr F T Hill, Waterville, chairman.

Cardiovascular Disease—Dr E E. Holt, Jr, Portland, chairman.

Laboratory Procedures and Their Relation to Clinical Medicine—Dr Julius Gottlieb, Lewiston, chairman

The Acute Surgical Abdomen—Dr F H. Jackson, Houlton, chairman.

Fractures—Dr Allan Woodcock, Bangor, chairman.

### ANTI-PNEUMOCOCCUS SERUM

The following facts relative to the availability of therapeutic serum in the different types of pneumonia have been recently announced by the State Board of Health and Welfare.

Therapeutic antipneumococcus serum is now available for Types 1, 2, 4, 5, 6, 7, 8 and 14. Typing stations are supplied with Types 1, 2, 5 and 7. Types 4, 6, 8 and 14 are available at the Augusta office, and will be supplied when a messenger is sent for them or will be shipped by first-class mail or express. It is eventually intended to supply Portland, Lewiston, Waterville, Bangor and Caribou with all available types. Types 3, 9, 11, 13, 18, 19, 20, 23, 28 and 29 are available only on special order from New York for individual cases, so no messenger should be sent to Augusta for these types. One may wire Augusta for the above special types. Other types are not available at present.

Serum is supplied free to indigent patients, those who can pay will be billed at cost. Relatives or neighbors should transport the specimens. Regular messenger service is not available in Augusta, and such transportation is not a regular function of the State Police.

### NOTES

The following members of the Maine Hospital Association appeared before the Budget Committee of the Legislature on November 29, 1938, and presented reasons why it was necessary for hospitals to receive more money for the care of the indigent sick. Mr Samuel Stewart (chairman), president, Central Maine General Hospital, Lewiston, Mr Robert Braun, president, Maine General Hospital, Portland, Mr George Eaton, president, Eastern Maine General Hospital, Bangor, Mr Carroll Perkins, Thayer Hospital, Waterville, Dr Stephen Brown, superintendent, Maine General Hospital, Portland, Dr Allan Craig, medical director, Eastern Maine General Hospital, Bangor, Dr Joelle C. Hiebert, president, Maine Hospital Association, Lewiston. The committee was cordially received by the Budget Committee, and it is hoped that larger appropriations will be granted shortly. This committee also prepared a lien bill for hospital service only.

The osteopaths are sponsoring two bills which are designed to compel general hospitals to give them the right to practice in them. The Maine Hospital Association plans to fight these bills vigorously.

Dr Samuel Levine, of Boston, was the guest speaker at the April 20 meeting of the Kennebec County Medical Society at the Gardiner General Hospital, Gardiner.

## CORRESPONDENCE

### ADMISSIONS TO STATE BOARD EXAMINATIONS

*To the Editor* I am enclosing a copy of the preliminary report of the Board of Registration in Medicine on admissions to the March, 1939, examination.

STEPHEN RUSHMORE, M.D., Secretary  
Board of Registration in Medicine,  
State House, Boston.

MISCELLANY

STAGE OF TUBERCULOSIS  
INFLUENCES PROGNOSIS

Hilleboe (Follow up study of patients discharged from tuberculosis sanatoria *Transactions of the Thirty-Fourth Annual Meeting of the National Tuberculosis Association, 1938*) succeeded in tracing 927 per cent of more than 5000 patients discharged from ten of the fifteen public tuberculosis sanatoriums in Minnesota during the ten year period, 1926-1935. Patients studied were about equally divided between rural and urban residents. Of the total number about 36 per cent were dead on discharge. This tremendous loss gives some measure of the tragic toll taken by this disease even during hospitalization when expert medical attention and every facility for treatment are available. Living and dead are classified, according to stage of disease, as shown approximately in Chart 1.

DISCHARGED PATIENTS

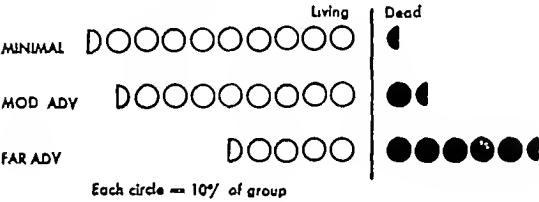

Chart 1

Stage of disease influences the length of time needed for recovery. In this study all patients were in the sanatorium for ninety days or more. Living patients, not including those who were admitted more than once were

LENGTH OF STAY IN SANATORIUM

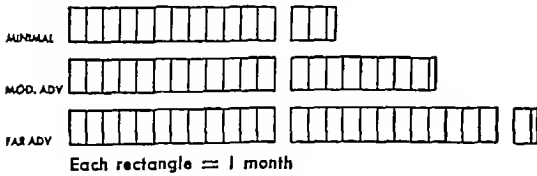

Chart 2

classified according to the average length of stay in the sanatorium and the stage of the disease. Chart 2 pictures roughly the result.

The influence of stage of disease on the condition at the

CONDITION ON DISCHARGE

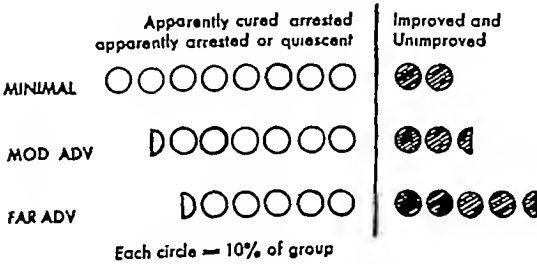

Chart 3

time of discharge was studied and the results confirmed the observation that the early case has a much better

chance of satisfactory recovery than has the advanced case. The result is summarized in Chart 3.

The probabilities of dying from any given disease can be calculated by actuaries with a fair degree of accuracy. In a person with tuberculosis the risk of dying is increased and this risk is in direct ratio to the stage of disease as shown in Chart 4.

'Statistical study of comparative mortality in discharged patients gives valid proof of the soundness of many clinical concepts regarding the disease. After all, one of the real values of statistics is to confirm the impressions of

RISK OF DYING INCREASED BY TUBERCULOSIS

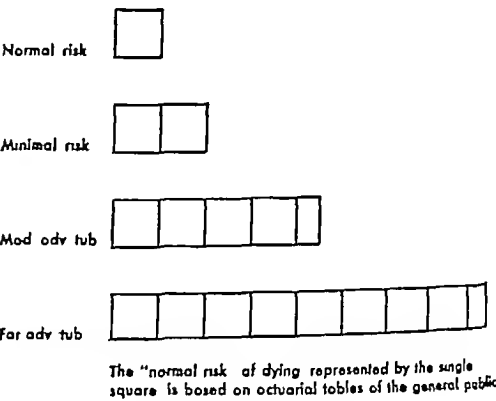

Chart 4

sound clinicians. Beneficial effects of early diagnosis of serious pulmonary tuberculosis lesions are reflected in the smaller risk of dying on the part of the minimal cases in comparison with the more advanced cases during the dangerous first five years after discharge. Tuberculosis must be diagnosed early' — Reprinted from *Tuberculosis Abstracts*, April, 1939.

## REPORT OF MEETING

### WILLIAM HARVEY SOCIETY

At a meeting of the William Harvey Society of Tufts College Medical School on Friday, February 10, in the Beth Israel Hospital auditorium, Dr. H. E. MacMahon introduced the speaker of the evening, Dr. William Boyd, professor of pathology and bacteriology at the University of Toronto. Dr. Boyd discussed the subject 'Nephritis. The basis of the clinical picture' in a style and manner familiar to all recent medical students and graduates who have enjoyed his textbooks.

Dr. Boyd began by describing the normal kidney and its function. The glomeruli (renal filters) and the tubules (concentrating mechanisms) go to make up the nephron, which is the unit of structure. In the glomeruli, proteins and colloids are held back in the blood stream, while crystalloids are allowed through in the tubules, the absorption of water, sugar and chlorides takes place, and the glomerular filtrate is thus concentrated to form urine. When absorption fails, an unconcentrated urine results, but if the tubular epithelium fails completely and disappears, then by experimental work in the tracing of the course of certain dyes it has been shown that the glomerular filtrate is wholly absorbed back into the tissues surrounding the tubules and anuria results. Anuria is, then, not a suppression of urine but a complete reabsorption of it. This has been shown to occur in cases with corrosive sublimate poisoning.

The glomerular filter can be described as a hand, the efferent and afferent arterioles forming the wrist and palm, the individual capillary loops, the fingers. The essential structure is the capillary finger projecting into the glomerular space. There are three elements to this capillary: a basement membrane, an endothelium consisting of cells spaced at intervals, and an epithelium consisting of a continuous layer of cells. A differential stain is necessary in demonstrating these elements. The key to Bright's disease is this capillary loop.

Dr. Boyd illustrated with lantern slides some remarkably clear-cut tissue sections of the kidney. The efferent arteriole from the glomerulus goes to the tubule, but its complete destruction will not result in tubular ischemia since a shunt exists, called 'Ludwig's vessel'.

From this, one might conclude that the glomerulus is the *sine qua non* of kidney function, but there are certain fishes whose kidneys have no glomeruli. Similarly, in advanced Bright's disease one can demonstrate nephrons consisting of healthy tubules and no glomeruli. These tubules must necessarily do the secreting for the absent glomeruli, but since they cannot secrete and absorb at the same time, the latter function is given up, and the result is an unconcentrated urine. Proof positive of Bright's disease is a low, fixed specific gravity for hours or days. Casts, cells, albumin, and so forth, are not pathognomonic but merely incidental. Pathologically, in advanced Bright's disease the most striking finding in sections examined microscopically is atrophy of the tubules.

Bright's disease is best classified as of two types. One is a true glomerulonephritis, the other, given various names, results in the same picture but arrives at it through

a narrowing of the arterioles. Glomerulonephritis is a non-suppurative inflammation, there are no foci of supuration, and the lesion is so disseminated as to suggest the action of a diffusible toxin, nearly always of streptococcal origin, from the nose, throat or nasopharynx. However, two great groups of poisons can cause the lesion: crystalloids—chemicals—pass the glomerular filter so easily as not to harm it, but on concentration in the tubules the poison becomes strong enough to damage the tubular epithelium, colloids, such as bacterial toxins, are of much larger molecular size and are therefore concentrated in the glomerular filter and produce damage there. As a result of this, the power of the glomerulus to hold back colloids is lost and thus the toxins are allowed to pass on and produce secondary damage to the tubules.

In glomerulonephritis there is exudation but not supuration. The glomerular tuft becomes far more cellular in appearance than normal, and this turns out, by differential staining, to be an endothelial proliferation. It is the first indication of the onset of ischemia, the loop narrows and eventually becomes occluded by hyaline thrombus formation. With the cutting off of blood supply, the filter is damaged and exudation of blood occurs into the glomerular space.

In hospital practice the sequence of events is not clearly seen because the patient's lifetime disease is often treated at various institutions. There are three stages: acute, subacute and chronic. In the acute stage the diffusible toxin in the circulation acts on all the glomeruli. As a rule the patient rarely dies at this stage but goes on to the next stage. Obviously, some of the glomeruli must recover, if the patient does, and the kidney sinks down and down only as recurring attacks take toll of the remaining ones. The patient who dies in the subacute stage has a large, white kidney, which is classically associated with the edematous, anemic patient. The kidney cortex is swollen, and there are doubly refractile lipid bodies in the epithelial cells. If the patient recovers from this stage, however, he goes on to the chronic stage, in which, post mortem, one sees loss of glomeruli, aglomerular tubules and a contracted kidney. Some healthy nephrons remain, which have carried the patient along, and these account for the gross picture of a nodular, scarred kidney. Microscopically, the striking thing is a disappearance of the normal number of renal tubules.

The other main type of Bright's disease is variously termed the arteriosclerotic, nephrosclerotic or hypertensive kidney, the essential lesion being thickening of the afferent arteriole and narrowing of its lumen so as to produce ischemia. Thus the same end result is obtained but by a different approach. This is the kidney of hypertension. Which is first, the hypertension or the arteriolar narrowing, is an academic question, Dr. Boyd believes that hypertension is primary.

Dr. Boyd made further comment on some of the principal symptoms of nephritis: (1) Albuminuria is the result of damage to the renal filter causing increase in its permeability. Tissue sections show this by the presence of coagulum in the capsular space. (2) Edema in the subacute stages is due to the failure of the osmotic pressure relations maintained by plasma colloids, which are lost in the urine. It is logical, therefore, that the first symptom be albuminuria, the second, edema. (3) Casts in the urine signify the large amount of albuminous material concentrated in the tubules so as to form molds. They incorporate whatever debris there is. (4) Inflammatory cells are present, of course, because this is an inflammation. Damaged epithelial cells are cast off. (5) With great damage and blocking, waste substances (nonprotein nitrogen)

# PRELIMINARY REPORT OF THE BOARD OF REGISTRATION IN MEDICINE ON ADMISSIONS TO MARCH, 1939, EXAMINATIONS

One hundred and ninety three candidates were examined. They can be arranged in three groups according to the school from which they graduated as follows: approved schools, non approved schools, osteopathic schools. Each group may be further subdivided into those taking the examination for the first time, those taking it for the second or third time, those taking it for the fourth or more time. Candidates who fail three times within one year must make out a new application which places them in the last group. Table 1 gives the figures in summary form.

schools is chronological according to the date on which the first graduate of each school filed application for this examination.

## COMMENT

There were in this examination no repeaters among the graduates of approved schools in the United States and Canada.

Of a total of 193 candidates examined, 120 were repeaters.

Of a total of 193 candidates examined, 112 were from non approved schools, reported as not eligible for admission to examination in any other state, and 19 osteopathic candidates for whom there are variations in the requirements of other states.

Of 52 graduates of approved schools taking the examination for the first time, 16 or about one third were from European universities (chiefly Continental).

## BOOK REVIEWS

*Shock and Related Capillary Phenomena* Virgil H. Moon 442 pp London, New York and Toronto Oxford University Press, 1938 \$3.50

This stimulating monograph represents the contribution of a pathologist to the solution of the problem of the etiology and mechanism of shock. The rather strange but apparently undeniable fact is pointed out that the vast

are inefficiently eliminated. Bright himself suspected this, and confirmed the suspicion by having a chemist determine the blood urea. (6) The rise in blood pressure, together with its mechanism, is a story in itself

Dr Boyd presented a chart showing the relation of symptoms to lesions. The glomerulus, through damage to the basement membrane, is responsible for albuminuria, low plasma proteins and edema, through its capillary endothelium, it gives rise to hematuria, hypertension and renal insufficiency. Damages to the tubules results in a loss of concentrating power and, hence, a urine of low specific gravity.

In conclusion, Dr Boyd suggested that a few beacons do stand out in the sea of perplexing problems concerning glomerulonephritis, these are damage to the renal filter, damage to the absorbing mechanism and ischemia.

MOSES J. STONE, M.D., announces the removal of his office to 520 Beacon Street, Boston.

### PHYSICIAN-IN-CHIEF, PRO TEMPORE, OLD HOME WEEK

During the week commencing Monday, April 24, a Physician in Chief, Pro Tempore, Old Home Week will be held at the Peter Bent Brigham Hospital. Those participating, each of whom has at some time served as physician-in-chief, pro tempore, at the hospital, include Dr. Lewellys F. Barker, Baltimore, professor of medicine, emeritus, Johns Hopkins University; Dr. Francis G. Blake, New Haven, Sterling Professor of Medicine, Yale University; Dr. Alvah H. Gordon, Montreal, associate professor of medicine, McGill University; Dr. Duncan Graham, Toronto, professor of medicine, University of Toronto; Dr. James B. Herrick, Chicago, professor of medicine, emeritus, Rush Medical College; Dr. Warfield T. Longcope, Baltimore, professor of medicine, Johns Hopkins University; Dr. O. H. Perry Pepper, Philadelphia, professor of medicine, University of Pennsylvania; Dr. David Riesman, Philadelphia, professor of clinical medicine, emeritus, University of Pennsylvania; and Dr. Rollin T. Woodyatt, Chicago, clinical professor of medicine, University of Chicago. The program is as follows:

#### WARD ROUNDS 10-12

Monday, April 24 Drs. Pepper (leader), Barker, Gordon, Riesman, Woodyatt.  
Tuesday, April 25 Drs. Riesman (leader), Barker, Blake, Gordon, Graham, Longcope, Pepper and Woodyatt.  
Wednesday, April 26 Drs. Longcope (leader), Barker, Blake, Gordon, Graham, Riesman and Woodyatt.  
Thursday, April 27 Drs. Herrick (leader), Gordon, Blake, Graham, Riesman and Woodyatt.  
Friday, April 28 Drs. Woodyatt (leader), Gordon and Riesman.  
Saturday, April 29 Staff Rounds. Drs. Gordon (leader), Riesman, Woodyatt and Christman and the medical staff of the Peter Bent Brigham Hospital.

#### AMPHITHEATER CLINICS 3:15-4:45

Monday, April 24 Drs. Barker and Riesman.  
Tuesday, April 25 Drs. Longcope and Pepper.  
Wednesday, April 26 Drs. Herrick and Gordon.  
Thursday, April 27 Drs. Graham and Woodyatt.  
Friday, April 28 Dr. Christman.

The afternoon amphitheater clinics are open to all physicians and students who may care to attend.

## HOSPITAL RESEARCH COUNCIL

The next meeting of the Hospital Research Council will be held in the Ether Dome of the Massachusetts General Hospital, on Tuesday, April 25, at 5:00 p.m.

#### PROGRAM

Vitamin C Lack After Major Surgery Dr. C. M. Jones.  
Prothrombin Determination. Dr. J. D. Stewart.  
Student Health Problems in Colleges Dr. A. V. Bock.  
Activity in the Cerebral Cortex During Anesthesia. Dr. H. K. Beecher.

HENRY K. BEECHER, M.D., *Secretary*

## MEDICAL CLINIC AT THE PETER BENT BRIGHAM HOSPITAL

At 3:30 p.m. on Thursday, April 27, in the amphitheater of the Peter Bent Brigham Hospital, Dr. James B. Herrick will give a medical clinic. Practitioners and medical students are cordially invited to attend.

## SIR WILLIAM OSLER HONOR SOCIETY

Dr. Abraham Myerson, professor of clinical psychiatry at Harvard Medical School, will deliver a lecture, illustrated by slides, on "Human Autonomic Pharmacology" at a meeting of the Sir William Osler Honor Society of the Middlesex University School of Medicine, to be held in the auditorium at 415 Newbury Street, Boston, at 8:00 p.m. on April 26. The medical profession is cordially invited to attend.

## JOINT MEETING OF THE SUFFOLK DISTRICT MEDICAL SOCIETY AND THE BOSTON MEDICAL LIBRARY

A joint meeting of the Suffolk District Medical Society and the Boston Medical Library will be held on Wednesday evening, April 26, at 8:15 p.m., at the Boston Medical Library, 8 Fenway, Boston.

#### PROGRAM

Official reports of the Society for 1938.  
Election of officers.  
Science and the Art of Deception. Dr. Francis G. Benedict.

Ladies are cordially invited to attend this meeting.

JAMES M. FAULKNER, M.D., *Secretary*  
Boston Medical Library

JOHN P. MONKS, M.D., *Secretary*  
Suffolk District Medical Society

## SUFFOLK CENSORS MEETING

The censors of the Suffolk District Medical Society will meet for the examination of candidates at the Boston Medical Library, 8 Fenway, Boston, on Thursday, May 4, at 4:00 p.m.

Candidates should make personal application to the secretary and present their medical diplomas at least one week before the examination.

JOHN P. MONKS, M.D., *Secretary*

## MIDDLESEX SOUTH DISTRICT MEDICAL SOCIETY

The annual meeting of the Middlesex South District Medical Society will be held at the Hotel Continental,

Cambridge, on Wednesday, May 3 The business meeting will begin at 11 30 a. m. At noon the annual oration will be delivered by Dr Roy D Halloran on Opportunities of the Psychiatric Hospital in the Mental Health Problem. Members in good standing are invited to the luncheon at 12 45 p. m.

FREO R. JOUETT, M.D., *President*,  
ALEXANDER A. LEVI, M.D., *Secretary*

## NEW ENGLAND SOCIETY OF PSYCHIATRY

The annual meeting of the New England Society of Psychiatry will be held at Kline Memorial Hall, Metropolitan State Hospital, Waltham, on Tuesday, April 25, at 12 o'clock noon. Inspection of the hospital will be followed by a luncheon and business meeting. Dr John W. Thompson and Dr William Corwin will speak on 'Some Observations on Patients Diagnosed as Having Schizophrenia.'

## NEW ENGLAND SOCIETY OF PHYSICAL MEDICINE

The regular meeting of the New England Society of Physical Medicine will be held at the Hotel Kenmore, Boston, on Wednesday evening, April 26, at 7 30 p. m. Dinner will be served at 6 00 p. m.

### PROGRAM

Back Strain Dr. Claude L. Payzant.  
Treatment of Flat Feet Dr. Howard Moore.  
Nerve Trauma Dr. Gordon M. Morrison.  
Therapeutic Exercises in Bursitis of the Shoulder Lucy G. Marshall.  
General discussion.

All members of the medical profession are cordially invited to attend.

WILLIAM D. MCFEE, M.D., *Secretary*

## SOCIETY MEETINGS AND CONFERENCES

### CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY, APRIL 24

#### TUESDAY APRIL 25

\*9 10 a. m. Here and There in Endocrinology Dr. Fuller Albright  
Joseph H. Pratt Diagnostic Hospital  
10 a. m. 12 30 p. m. Tumor clinic Boston Dispensary  
5 p. m. Hospital Research Council Ether Dome, Massachusetts General Hospital  
8 15 p. m. Harvard Medical Society Amphitheater Peter Bent Brigham Hospital (Shattuck Street entrance)

#### WEDNESDAY APRIL 26

9 10 a. m. Hospital case presentation Dr. S. J. Thannhauser  
Joseph H. Pratt Diagnostic Hospital  
12 m. Clinicopathological conference Children's Hospital amphitheater  
7 30 p. m. New England Society of Physical Medicine. Hotel Kenmore Boston  
8 p. m. Sir William Osler Honor Society Middlesex University School of Medicine auditorium 415 Newbury Street Boston  
8 15 p. m. Joint meeting of the Suffolk District Medical Society and the Boston Medical Library Boston Medical Library

#### THURSDAY APRIL 27

8:00-9:30 a. m. Exchange visit Surgical and Orthopedic Staffs of the Peter Bent Brigham and Children's hospitals held this week at the Children's Hospital Orthopedic  
9 10 a. m. Alcohol Chemical tests for alcoholism Dr. Sydney Selesnick. Joseph H. Pratt Diagnostic Hospital  
3 30 p. m. Medical clinic at the Peter Bent Brigham Hospital

#### FRIDAY APRIL 28

9 10 a. m. Heredity and Environment in Relation to Intelligence, Personality and Mental Disease Dr. Abraham Myerson. Joseph H. Pratt Diagnostic Hospital

\*10 a. m. 12 30 p. m. Tumor clinic Boston Dispensary  
12 m. Clinical meeting of the Children's Medical Service Massachusetts General Hospital Ether Dome.  
4 p. m. New England Heart Association House of the Good Samaritan. 6-30 p. m. annual dinner Harvard Club 8 15 p. m. Boston Medical Library

#### SATURDAY APRIL 29

\*9 10 a. m. Hospital case presentation Dr. S. J. Thannhauser  
Joseph H. Pratt Diagnostic Hospital  
\*10 a. m. 12 m. Staff rounds of the Peter Bent Brigham Hospital

\*Open to the medical profession

## BOOK REVIEWS

*Shock and Related Capillary Phenomena* Virgil H. Moon 442 pp London, New York and Toronto Oxford University Press, 1938 \$3.50

This stimulating monograph represents the contribution of a pathologist to the solution of the problem of the etiology and mechanism of shock. The rather strange but apparently undeniable fact is pointed out that the vast

literature on this problem has emanated almost solely from surgeons and physiologists, without the corroborative evidence available in morphologic pathology, which, it is believed, furnishes convincing proof that shock is due to diminished blood volume and flow dependent on the leakage of plasma into the tissues as a result of increased permeability of the capillary endothelium and on an enormous increase in the capacity of the capillary bed, especially in visceral areas, with consequent stagnation and increased concentration and viscosity of the blood. The chief theories variously ascribing the universally admitted circulatory failure of shock to a weakened myocardium, to exhaustion of a vasomotor nerve center, to a failing venopressor mechanism, to decreased alkali reserve and acapnia and to hypothetical poisonous substances liberated from injured tissues are critically reviewed and evaluated, and their apparently untenable features pointed out. The structure and function of capillaries,—normal and pathologic,—as revealed in recent studies, are described, and the fact emphasized that they are endothelial tubes capable of contraction and dilatation, possibly under vasomotor control but certainly under the influence of substances freed from tissue cells suffering from anoxia. This is the key to the vicious circle of shock: tissue anoxia, dilatation and increased permeability of capillaries, stagnation and concentration of blood, increased tissue anoxia. It is pointed out that the circulatory failure characterizing a wide variety of conditions—burns, anaphylactic shock, poisoning by food, bee sting, snake venom, peptones or various mineral agents, metabolic intoxications, acute infections, acute abdominal emergencies and peritonitis—is due to the same alteration of capillary function. Congestion of the viscera is regularly recorded in the necropsy records of all these conditions and is usually interpreted as “passive congestion due to heart failure,” whereas the condition is actually acute capillovenous congestion and congestive circulatory failure, which are not to be ascribed to myocardial weakness except in cases of demonstrable cardiac defect or degeneration.

Dr Moon's monograph is not lacking in practical applications of his theory of shock. He points out that hemoconcentration, which is fairly easily demonstrable by simple methods, occurs before any marked fall of blood pressure, which is maintained by the efficiency of the myocardium and the vasoconstrictor center, this is the earliest detectable manifestation of shock and the most accurate index of its severity. He discusses the logic of various therapeutic methods and emphasizes the primary need to restore blood volume and capillary tonus and to correct anoxia. He has succeeded admirably in integrating the mass of factual information about shock—derived from more than 400 titles in the appended bibliography. Doubtless it will be a long time before the last word is written about shock, but Dr Moon's discriminating review of the literature and his application of the evidence afforded by pathology to the solution of the problem constitute an important contribution.

*Diagnostic Standards Tuberculosis of the lungs and related lymph nodes* 32 pp Tentative edition New York National Tuberculosis Association, 1938

This pamphlet, which is the eleventh in a series published by the National Tuberculosis Association, is a tentative one, and hence comments are requested. So long as the diagnosis and treatment of pulmonary tuberculosis undergo changes, so long will our conceptions and standards have to be revised to conform with the best opinions of the day.

It is noteworthy that the terms “childhood type” and “adult type” have been replaced by “primary tuberculosis” and “reinfection tuberculosis” respectively. Although the latter terms hardly describe the true underlying lesions, as no infection is strictly primary and one cannot draw the line between primary infection and reinfection, nevertheless they give a better concept of the pathologic changes than did the earlier terms.

Another section worth mentioning is the paragraph defining the minimum standard for a “negative sputum.” This is no longer a haphazard term, but requires that at least three adequate specimens per month shall have been found to be negative, both by direct smear and by concentration. For patients to be designated as apparently “cured,” the sputum must remain negative to repeated cultures and animal inoculations.

The reviewer wonders why nothing was said about the erythrocytic sedimentation rate and differential leukocyte studies. It appears to be universally accepted that a case cannot be designated as apparently cured unless the sedimentation rate is within normal limits. It is hoped that the above laboratory studies will be included in the next edition.

*Control of Conception* Robert L. Dickinson Second edition 390 pp Baltimore Williams & Wilkins Co., 1938 \$3.50

In his book the author has gone into the whole subject of the control of conception in a most systematic, painstaking manner. The effectiveness of the various types of prevention is thoroughly discussed, and explained in great detail. The entire book is carefully illustrated by his own drawings. For those physicians who want a complete, authoritative work on the subject of contraception, this book will prove very satisfactory.

The laity has so many times confused the control of conception with abortion that it seems to the reviewer inadvisable for Dr Dickinson to have included the indications and technic of abortion in this otherwise excellent book.

*A Manual of Reparative Plastic Surgery* J. Eastman Sheehan 311 pp New York and London Paul B Hoeber, Inc., 1938 \$5.50

Since the World War there has been a growing interest in reparative plastic surgery. As a result, in addition to papers appearing in surgical journals, many books have been published on the subject. This interest is undoubtedly due to an increase of traumatic injuries from automobile and other civilian accidents.

Dr Sheehan's book is printed in good type. It is profusely illustrated with diagrams and photographs which are very helpful. The author has divided the book into two parts. The first is directed to general consideration of principles of plastic repair, while the second describes various plastic operations.

A more critical survey indicates that, while certain subjects, such as plastic operations on the eyelids and the nose, are well covered, other sections are quite incomplete. This is particularly true concerning mandibular defects and reconstructive problems.

The point is rapidly being reached at which no single book on plastic surgery will be anything more than an introduction to the subject. The field as a whole has become unusually wide, and a book of the sort being reviewed, aside from providing a panorama of high lights, has its chief value in presenting the author's own particular clinical contributions and methods of procedure. In this last respect this volume should prove of value.

## BLOOD DYSCRASIAS\*

With Special Reference to Splenectomy

J H J UPHAM, M.D.†

COLUMBUS, OHIO

IN discussing the subject of blood dyscrasias, with special reference to splenectomy, it is my intention to review the work of Drs Doan, Wiseman and Curtis, in the Spleen Clinic of the College of Medicine of Ohio State University, and to add some data in support of their published arguments for the performance of splenectomy in selected clinical conditions at times when prevailing surgical opinion has been quite definitely against operative interference. I shall restate the scientific basis for their position.

The spleen is one of those enigmatic organs of the body which, while apparently yielding freely its secrets of structure, both gross and microscopic, has, as it were, been holding back some hidden qualities having powerful influences on the maintenance of health, and under certain circumstances, even becoming capable of producing serious disturbances.

Probably the main reason for our tardiness in learning more of the splenic factor in certain human blood dyscrasias is the absence of finding such dyscrasias in animals, and the failure as yet to produce them experimentally.

While we, therefore, owe much of our knowledge of the anatomy and physiology of the spleen to animal studies, it is perforce normal anatomy and normal physiology. However, by careful clinical observations, by studies of the blood using the latest technics, by examination of materials obtained at biopsy, during major surgery and from the autopsy, very definite and suggestive data have been accumulated.

I need not discuss the anatomy or dilate upon the generally accepted physiology of this organ.

Since Barcroft's work, the spleen has been regarded as a physiologic reservoir of red blood cells. It contracts during periods of physical activity to discharge an increased number of red cells to carry additional oxygen to the tissues. It functions as the "graveyard" for blood cells, and probably helps to conserve the iron of the destroyed red cells, and it may be that in the breaking up of these latter there is set free some chemical stimulant to fresh red-cell production.

The attention of Doan<sup>1</sup> and his associates has been particularly directed in the last few years to the destructive activity of the spleen for various blood elements in certain of the primary blood dyscrasias.

It has been the experience in medicine that whenever any physiologic function is recognized for any organ, a disease entity due to a corresponding pathologic dysfunction may be anticipated, and sooner or later will be encountered. Thus, in congenital hemolytic jaundice there is recognized a simple dominant, familial tendency for the normal physiologic erythroclastic function of the spleen to become overemphasized to the point of definite pathologic manifestations.

First observed by Murchison in 1885, established as a clinical entity by Hayem thirteen years later, and its familial occurrence recorded by Minkowski at the turn of the century, hemolytic jaundice remains, nevertheless, a frequently unrecognized pathologic state, and this despite signs always and symptoms frequently which should make the diagnosis relatively simple.

With Lord Dawson of Penn<sup>2</sup> and an increasing group of clinical observers it is the belief of the Ohio State University investigators<sup>3</sup> that true hemolytic icterus is always the manifestation of an inherited constitutional defect, characterized, when clinically active, by recurring "crises of deglobu-

\*Presented at the annual meeting of the New Hampshire Medical Society, Manchester, May 16, 1938.

†Professor of Medicine, Ohio State University College of Medicine; attend physician, University Hospital, Columbus, Ohio.

lization," marked microcytic normochromic or hyperchromic anemia, increased erythrocyte fragility, unusually high reticulocytosis, acholuric icterus and splenomegaly

Evidences of the disease may be present at birth or may first appear in any decade, however, the inherited tendency may be carried and transmitted without the development of clinical manifestations. Furthermore, the severity and frequency of clinical disease may vary widely from family to family, thus making it essential to have the requisite laboratory studies in a sufficiently representative sampling of blood relatives before an exclusion of the hereditary element in an apparently sporadic or "acquired" case is justified. In all but 1 of the 15 families studied in Columbus the individual first seen with clinical symptoms knew nothing of the character of his "jaundice" or "anemia" and was entirely unaware, as were the other members of the family, of the presence of any hereditary disease, though it existed in more or less obvious degree in representatives of each generation available for examination.

The importance of recognizing this constitutional defect, when it exists, lies in the fact that a fatal relapse or exacerbation of the disease may occur spontaneously, or be precipitated by infection or trauma, in any decade of life, and that, with the institution of adequate therapy (splenectomy) either as a prophylactic or curative measure, the clinical results are highly satisfactory and permanent.

It was the study of the more chronic phases of this disease and the analysis of the changes induced by splenectomy, under these admittedly favorable circumstances, which formed the basis for the first excursion of our research group<sup>4</sup> into the realm of human splenic pathologic physiology. Two principal objectives motivated these observations, first, the determination of the natural history of the disease, which necessitated long periods of observation with serial laboratory studies in the same individual prior to any therapeutic intervention, and second, an analysis of the immediate as well as the more remote changes in the cellular and chemical constituents of the blood following the removal of the spleen.

These data have a direct bearing on the question of the relative roles of spleen and bone marrow in the causation of this disease syndrome, and thereby form the essential basis for the establishment of the principle of splenectomy as a rational therapeutic measure, which data, if judged sufficient for the quiescent phases of the disease, should apply as well in directing therapy in the more acute phases.

In the first study<sup>4</sup> of clinical cases of chronic con-

genital hemolytic jaundice in our clinic, daily estimations of the various cell levels were made for periods of three months or longer to establish thoroughly the range of fluctuation existing before operative intervention was undertaken. Then, on the day of operation, blood studies were made at fifteen-minute to half-hour intervals throughout the day, with the astonishing discovery that instead of the erythrocyte increase, as described in the literature, coming in from one to three months following the removal of the spleen a major increase, frequently of 1,000,000 or more red blood cells per cubic millimeter occurred immediately, before the patient left the operating table, irrespective of the preoperative level of the total red cells.

This phenomenon was observed not occasionally or sporadically but regularly, whenever sufficient hematologic studies were made. The lower the red-cell level, and the more active the hemolytic process, the more dramatic the response. Blood volume studies proved this erythremia to be not simply a relative cell increase, dependent on some loss in plasma volume, but established as the more important element in the equation an immediate large significant increase in the actual circulating erythrocytic cell volume. Hemoglobin, leukocytes and thrombocytes likewise rose promptly, coincident with dramatic clinical improvement. A progressive decrease in the icteric index and the reticulocytes, which always follows removal of the spleen in hemolytic jaundice, and a readjustment in the iron level of the plasma reflected the elimination or subsidence of the hemolytic process. Moreover, an increase in the blood cholesterol to normal, the gradual return of the red cells to a more nearly normal diameter and volume, and the resumption of a more nearly normal range of erythrocytic resistance seemed to be evidence of a better product, delivered under less urgent and stressful circumstances by a bone marrow released from an abnormal and inimical splenic influence. In short, the data obtained suggested that the disgorgement of the sequestered blood cells from the splenic reservoir incident to operation and the sudden elimination of the destructive activity of the splenic phagocytes render more effective the unusually active erythropoiesis and erythrocytic delivery that characterize the bone marrow in hemolytic anemia.

Up to the present time, our investigators<sup>1</sup> have studied more or less thoroughly 85 blood relatives in 15 families, finding evidences of the trait in 40, and have seen the removal of the spleen successfully accomplished in 17 clinically active cases. Complete data have been obtained concerning all patients who have been operated on. In this group, removal of the spleen was accomplished in 5

patients during a quiescent interlude of the disease as a prophylactic procedure, in 5 patients, operative intervention was decided on during a subacute exacerbation of the hemolytic process, and in 7 critically ill patients the spleen was removed as an emergency procedure with the total red-cell count rapidly approaching or actually under 1,000,000 cells per cubic millimeter in a fulminant, acute, hemoclastic crisis

#### RATIONALE OF SPLENECTOMY IN ACUTE HEMOCLASTIC CRISES

The gradual accumulation of such facts as have been cited formed the background for a growing conviction that, given proper medical judgment and adequate surgical management, the patient in acute erythroclastic crisis should respond even more dramatically and promptly to the surgical removal of the spleen than those seen in the subacute and chronic phases

During the past three years, on seven separate occasions, our staff has been faced with the problem of critically severe, progressive, acute erythroclastic crises in patients with an age range from four to fifty-six years. In several cases, intensive liver therapy and repeated blood transfusions had failed to encourage a remission. The anemia with its attendant manifestations became so severe as to threaten imminent death, yet no remediable cause could be found other than the persistent exacerbation of the underlying congenital hemolytic process

One might conclude from the literature that such critical crises are exceedingly rare, inasmuch as deaths are seldom reported and spontaneous remissions are known usually to follow a hemolytic episode. Such has not been the experience in our clinic. In no instance has splenectomy been undertaken in the stage of acute crisis except after the failure of every medical means and as an emergency lifesaving measure

The confusion of this condition in its more acute phases with certain other anemic states may account for the rarity of its mention in the past and the universal surgical dictum against splenectomy. The important diagnostic points have already been listed, together with the warning that any one or more of the cardinal features, including clinical jaundice, may be absent in the individual patient. Nevertheless, the identification of this disease is all that is necessary to bring it under control in practically 100 per cent of cases, if the pathologic physiology of the spleen is adequately understood, and its relation to the hemolytotoxic equilibrium recognized. All 7 of the patients in acute crisis who were subject to splenectomy at a time when the total red cells were at

or near the 1,000,000 mark showed a spectacular clinical response on the operating table, all survived, and each returned promptly to a normal hemolytotoxic balance. Accurate diagnosis, adequate medical management once the diagnosis was established, and careful surgical technic were the essentials of success. Neither the cause of the crisis, the severity of the anemia, nor the obviously critical clinical condition of the patient has been sufficient to cause us to withhold operative intervention

The seriousness of the surgical risk in hemolytic icterus is not to be measured in terms of the usual criteria, because of the autotransfusion which occurs coincident with the operative manipulation of the spleen itself, the immediacy of the reversal in the hemolytic mechanism involved, and the essential integrity of the marrow. Were the bone marrow chiefly responsible for the clinical manifestations of hemolytic icterus, particularly in the crises, an operative procedure would only further embarrass this organ. Instead, a hyperplastic marrow producing new red cells at a rate sufficient to maintain reticulocytes at 100 per cent in the circulating blood, but still unable to establish a positive erythrocyte balance, at once becomes adequate, and there is evidence (rapid decrease in reticulocytes) of a lessened functional demand immediately following splenectomy

#### THE SPLEEN AND WHITE-CELL EQUILIBRIUM

Krumbhaar<sup>5</sup> has noted the prompt thrombocytosis, granulocytosis and monocytosis and the tardy lymphocytosis which follow the removal of the normal mammalian spleen. In hemolytic icterus with splenomegaly our investigators have called attention to the frequency with which a moderate thrombocytopenia and leukopenia have been encountered and the characteristic increase in these elements, as well as in the red blood cells, which follows splenectomy. Experimental studies<sup>6</sup> have demonstrated a physiologic sequestration function of the spleen for white blood cells and blood platelets which make this mechanism a potentially important factor to be considered when these elements are found to be deficient in patients

One of the most constant and characteristic differential diagnostic points in Banti's syndrome is the profound leukopenia which occurs. There are at present three methods of treating Banti's disease: the medical with blood transfusions as necessary following hemorrhage and with liver extract and a high-carbohydrate dietary regime in the interims, the surgical, with splenectomy in the early cases where possible, and ligation of the splenic artery in those late cases where, because of adhesions and dilated veins, the spleen cannot

lization," marked microcytic normochromic or hyperchromic anemia, increased erythrocyte fragility, unusually high reticulocytosis, acholuric icterus and splenomegaly

Evidences of the disease may be present at birth or may first appear in any decade, however, the inherited tendency may be carried and transmitted without the development of clinical manifestations. Furthermore, the severity and frequency of clinical disease may vary widely from family to family, thus making it essential to have the requisite laboratory studies in a sufficiently representative sampling of blood relatives before an exclusion of the hereditary element in an apparently sporadic or "acquired" case is justified. In all but 1 of the 15 families studied in Columbus the individual first seen with clinical symptoms knew nothing of the character of his "jaundice" or "anemia" and was entirely unaware, as were the other members of the family, of the presence of any hereditary disease, though it existed in more or less obvious degree in representatives of each generation available for examination.

The importance of recognizing this constitutional defect, when it exists, lies in the fact that a fatal relapse or exacerbation of the disease may occur spontaneously, or be precipitated by infection or trauma, in any decade of life, and that, with the institution of adequate therapy (splenectomy) either as a prophylactic or curative measure, the clinical results are highly satisfactory and permanent.

It was the study of the more chronic phases of this disease and the analysis of the changes induced by splenectomy, under these admittedly favorable circumstances, which formed the basis for the first excursion of our research group<sup>4</sup> into the realm of human splenic pathologic physiology. Two principal objectives motivated these observations, first, the determination of the natural history of the disease, which necessitated long periods of observation with serial laboratory studies in the same individual prior to any therapeutic intervention, and second, an analysis of the immediate as well as the more remote changes in the cellular and chemical constituents of the blood following the removal of the spleen.

These data have a direct bearing on the question of the relative roles of spleen and bone marrow in the causation of this disease syndrome, and thereby form the essential basis for the establishment of the principle of splenectomy as a rational therapeutic measure, which data, if judged sufficient for the quiescent phases of the disease, should apply as well in directing therapy in the more acute phases.

In the first study<sup>4</sup> of clinical cases of chronic con-

genital hemolytic jaundice in our clinic, daily estimations of the various cell levels were made for periods of three months or longer to establish thoroughly the range of fluctuation existing before operative intervention was undertaken. Then, on the day of operation, blood studies were made at fifteen-minute to half-hour intervals throughout the day, with the astonishing discovery that instead of the erythrocyte increase, as described in the literature, coming in from one to three months following the removal of the spleen a major increase, frequently of 1,000,000 or more red blood cells per cubic millimeter occurred immediately, before the patient left the operating table, irrespective of the preoperative level of the total red cells.

This phenomenon was observed not occasionally or sporadically but regularly, whenever sufficient hematologic studies were made. The lower the red-cell level, and the more active the hemolytic process, the more dramatic the response. Blood volume studies proved this erythremia to be not simply a relative cell increase, dependent on some loss in plasma volume, but established as the more important element in the equation an immediate large significant increase in the actual circulating erythrocytic cell volume. Hemoglobin, leukocytes and thrombocytes likewise rose promptly, coincident with dramatic clinical improvement. A progressive decrease in the icteric index and the reticulocytes, which always follows removal of the spleen in hemolytic jaundice, and a readjustment in the iron level of the plasma reflected the elimination or subsidence of the hemolytic process. Moreover, an increase in the blood cholesterol to normal, the gradual return of the red cells to a more nearly normal diameter and volume, and the resumption of a more nearly normal range of erythrocytic resistance seemed to be evidence of a better product, delivered under less urgent and stressful circumstances by a bone marrow released from an abnormal and inimical splenic influence. In short, the data obtained suggested that the disgorgement of the sequestered blood cells from the splenic reservoir incident to operation and the sudden elimination of the destructive activity of the splenic phagocytes render more effective the unusually active erythropoiesis and erythrocytic delivery that characterize the bone marrow in hemolytic anemia.

Up to the present time, our investigators<sup>1</sup> have studied more or less thoroughly 85 blood relatives in 15 families, finding evidences of the trait in 40, and have seen the removal of the spleen successfully accomplished in 17 clinically active cases. Complete data have been obtained concerning all patients who have been operated on. In this group, removal of the spleen was accomplished in 5

splenectomy in the acute cases may be explained on the basis of two extenuating circumstances the difficulty of accurate differential diagnosis in terms of underlying etiology, which has resulted in the inclusion of other than true thrombocytolytic or splenic inhibitory thrombopenic cases in the statistical surveys of the past, and the materially greater operative risks which formerly attended splenectomy per se and which have been decidedly lessened through an increased efficiency in both the medical preparation and surgical handling of these patients

In an analysis of the literature, Marsh<sup>11</sup> was impressed with the fact that blood transfusion was used in none of the 10 acute cases operated on prior to 1925 except the 1 in which recovery was reported, whereas in the 4 successful cases recorded during the succeeding five years blood transfusion had been an immediate preoperative procedure in each. He concludes that the platelet count does not seem to be a factor in the surgical prognosis, but that transfusion and the red-cell and hemoglobin levels are exceedingly important. Our experience<sup>1</sup> would bear out the importance of preoperative transfusion to ensure adequate hemostasis, but where the spleen is involved, because of the intimate relation it bears to the formation, storage and destruction of blood elements, the actual preoperative level of the red cells is not so important. The normal cellular levels are more certainly and promptly attained by splenectomy through the adjusted hemolytopoietic equilibrium than they are by repeated blood transfusions.

The theory of the hyperpermeability of the vascular endothelium as the fundamental pathologic lesion in hemorrhagic purpura need only be mentioned. Bedson<sup>12</sup> has shown that both platelet deficiency and endothelial damage are at times essential to the experimental production of purpuric manifestations and that sometimes one and sometimes the other may present the chief conditioning factor in the syndrome. Koster<sup>13</sup> explains the thrombopenia as the result of increased phagocytosis of platelets plus a dysfunction in thrombopoiesis. Duke<sup>14</sup> has suggested endothelial permeability as the primary cause, with the consequent increased demand for platelet plugs responsible for the development of the thrombopenia. Infectious foci may liberate toxic substances which result, through some of the above mechanisms, in purpuric manifestations. Many patients with functionally and quantitatively adequate thrombocytes exhibit a hemorrhagic diathesis, usually mild and exceedingly chronic, and vitamin C, an antiscorbutic, intercellular-substance vitamin, sometimes, but not always, corrects this tendency. An allergic basis has been established in some patients, with improvement after elimination diets or following

adequate desensitization therapy. There remain, however, in the opinion and experience of our investigators, after every other causative factor has been eliminated, a group of essential thrombocytopenic purpuras with the sternal bone marrow showing normal megakaryocytes, both in number and in quality, in which it has been impossible to obtain permanent benefit without removal of the spleen. In their experience, deep x-ray therapy has not been found to be a successful substitute in these cases.

There are obviously many factors that influence blood coagulation and extravasation which are not now known, and a more rational approach must await further information. One case will indicate the sequence of events when splenectomy is successful in the treatment of purpura. A young lady with purpura, more or less recent and acute in onset, showed an almost complete absence of platelets and no thrombocyte response to the adrenal test. There was, however, marked evidence of bone-marrow activity, exemplified in a leukocytosis of 30,000 and a reticulocytosis of 57 per cent. The spleen was normal in size and nonpalpable, and after removal, showed no microscopic evidence of endothelial or clasmotocytic hyperplasia. Within twenty-four hours of the last critical relapse to 600,000 erythrocytes, and after two emergency blood transfusions totaling 1100 cc., removal of the spleen was successfully accomplished. The platelets reappeared immediately in the circulation on the day of operation and convalescence was prompt and uneventful. All medical measures, including repeated blood transfusions had failed during the sixteen days of hospital observation, the condition on two occasions having become critical due to excessive blood loss. The behavior of the platelets suggests that, following splenectomy, the removal of the phagocytic clasmatocytes with this organ immediately released to the circulation those units which the bone marrow had been producing and that the secondary rise later may have been due to the increased megakaryocytic activity following elimination of some splenic inhibitory effect. This patient has remained well with high thrombocyte levels at all times during the past three years. One year after splenectomy, a normal baby was delivered at term after an uneventful pregnancy, but the platelets in the infant were definitely low, 150,000 to 200,000 per cubic millimeter. The study is being continued.

The thrombocytosis, described by Krumbhaar, Evans and others, which follows splenectomy has received striking and complete confirmation in our series of patients. In the majority of cases the blood platelets rose to levels well above 1,000,000 per cubic millimeter, and only once was there a failure of the thrombocytes to show a

be removed with safety. Each method has its own particular advocates and our workers have had personal experience with all three. Only if the spleen is successfully removed is there an elimination of the leukopenia, and this change is dramatic and permanent when it occurs. With the ligation of the splenic artery there is a gradual diminution in the size of the spleen and the white-cell count may increase to 2000 or 2500 per cubic millimeter, but the tendency to recurrent esophageal hemorrhages and to progressive hepatic cirrhosis is not appreciably diminished.

Individuals who refuse operation or in whom neither splenic-artery ligation nor splenectomy can be successfully accomplished receive some symptomatic relief from the medical regime mentioned and suffer only occasional attacks of acute hepatic distress. Because of the complete correction of the leukopenia and because there has seemed in our small series of patients to have been a less rapid progression of the hepatic insufficiency, as measured by available tests, after removal of the spleen, it is our present belief that the attempt should be made to diagnose Banti's syndrome early and to remove the spleen promptly, if possible. Long-time follow-up studies in this group of patients and a more complete knowledge of the etiology of this disease must precede any final authoritative conclusions.

#### THE SPLEEN AND THROMBOCYTOPENIA

A single etiology for thrombocytopenic purpura hemorrhagica is not known, the pathology is ill-defined and varied, and the differential diagnosis is frequently difficult to establish. After long years of study by many investigators such continues to be the present status of this problem. The reason is quite apparent. The mechanism involved in the maintenance of the fluidity of the blood is so complex, and the vulnerable points at which some small deflection may result in hemorrhage are so numerous, that each patient presenting with a syndrome which includes a bleeding tendency must be subjected to the minutest scrutiny before a successful rationale of treatment may be outlined. While we are quite familiar in our own clinic, and as recorded in the medical literature, with the multiplicity of symptomatic purpuric states, with the frequency of spontaneous remissions in the idiopathic cases, and with the efficacy at times of properly administered and repeated blood transfusions in inducing remissions, we are concerned at this time only with those cases which show a definite thrombopenia associated with some splenic abnormality, and more particularly with the very acute fulminating case that presents an immediate clinical emergency.

The following objective criteria have been quite well agreed on as a starting point and as the *sine qua non* for the placing of any given hemorrhagic syndrome under the general heading of true purpura: a low or absent platelet count, a prolonged bleeding time, a normal clotting time, but a failure of the clot to retract, spontaneous or induced petechiae (positive tourniquet test), a leukocytosis, and perhaps reticulocytosis (which rule out a general marrow hypoplasia), and an absence of abnormalities in red or white cells indicative of pernicious anemia, leukemia or other foreign cellular metaplasia in the marrow inimical to megakaryocytic activity.

Denys, in 1887, first called attention to the relation which exists between decreased blood platelets and hemorrhagic disease. It was not, however, until November, 1916, that Kaznelson,<sup>7</sup> of Prague did the first splenectomy for "thrombocytolytic purpura," basing his action, as the name implies, on the hypothesis of the destructive activity of this organ for these elements.

Frank,<sup>8</sup> on the other hand, while recognizing the value of removal of the spleen for what he termed "essential thrombopenia," based his advocacy of this procedure on the assumption that the reduction in platelets was due to an inhibitory action of the spleen on the bone marrow. This division of opinion has persisted to the present time among clinical investigators, with the majority favoring Kaznelson's interpretation. It would seem to us that all are correct. Both inhibitory and lytic functions have been equally well established for the spleen.

The beneficial effects of splenectomy may arise through either mechanism. The dangers attending splenectomy in the acute hemorrhagic diatheses have been repeatedly emphasized. Whipple,<sup>9</sup> in 1926, reviewed 81 cases of splenectomy for hemorrhagic purpura, there were only 6 deaths among the 73 cases classified as chronic, while 7 of the 8 acute cases died. Two years later, Spence<sup>10</sup> collected 101 cases, with satisfactory clinical results reported in 75. Eight only of the 80 chronic patients died as a result of the operation, while 10 of the 12 acute cases were fatal. The duration of the hemorrhages was not given in 9 cases.

Such statistical studies have resulted quite naturally in a warning against operative interference in the presence of the more acute purpuric manifestations, dependence being placed preferably on repeated transfusions in the attempt to induce a more quiescent phase of the disease. Blood transfusion is, of course, lifesaving and, of necessity, is used as an emergency measure in every case of extensive, acute hemorrhage. However, we believe that the high mortality rate now attributed to

splenectomy in the acute cases may be explained on the basis of two extenuating circumstances the difficulty of accurate differential diagnosis in terms of underlying etiology, which has resulted in the inclusion of other than true thrombocytolytic or splenic inhibitory thrombopenic cases in the statistical surveys of the past, and the materially greater operative risks which formerly attended splenectomy per se and which have been decidedly lessened through an increased efficiency in both the medical preparation and surgical handling of these patients

In an analysis of the literature, Marsh<sup>11</sup> was impressed with the fact that blood transfusion was used in none of the 10 acute cases operated on prior to 1925 except the 1 in which recovery was reported, whereas in the 4 successful cases recorded during the succeeding five years blood transfusion had been an immediate preoperative procedure in each. He concludes that the platelet count does not seem to be a factor in the surgical prognosis, but that transfusion and the red-cell and hemoglobin levels are exceedingly important. Our experience<sup>1</sup> would bear out the importance of preoperative transfusion to ensure adequate hemostasis, but where the spleen is involved, because of the intimate relation it bears to the formation, storage and destruction of blood elements, the actual preoperative level of the red cells is not so important. The normal cellular levels are more certainly and promptly attained by splenectomy through the adjusted hemolytopoietic equilibrium than they are by repeated blood transfusions.

The theory of the hyperpermeability of the vascular endothelium as the fundamental pathologic lesion in hemorrhagic purpura need only be mentioned. Bedson<sup>12</sup> has shown that both platelet deficiency and endothelial damage are at times essential to the experimental production of purpuric manifestations and that sometimes one and sometimes the other may present the chief conditioning factor in the syndrome. Koster<sup>13</sup> explains the thrombopenia as the result of increased phagocytosis of platelets plus a dysfunction in thrombopoiesis. Duke<sup>14</sup> has suggested endothelial permeability as the primary cause, with the consequent increased demand for platelet plugs responsible for the development of the thrombopenia. Infectious foci may liberate toxic substances which result, through some of the above mechanisms, in purpuric manifestations. Many patients with functionally and quantitatively adequate thrombocytes exhibit a hemorrhagic diathesis, usually mild and exceedingly chronic, and vitamin C, an antiscorbutic, intercellular-substance vitamin, sometimes, but not always, corrects this tendency. An allergic basis has been established in some patients, with improvement after elimination diets or following

adequate desensitization therapy. There remain, however, in the opinion and experience of our investigators, after every other causative factor has been eliminated, a group of essential thrombocytopenic purpuras with the sternal bone marrow showing normal megakaryocytes, both in number and in quality, in which it has been impossible to obtain permanent benefit without removal of the spleen. In their experience, deep x-ray therapy has not been found to be a successful substitute in these cases.

There are obviously many factors that influence blood coagulation and extravasation which are not now known, and a more rational approach must await further information. One case will indicate the sequence of events when splenectomy is successful in the treatment of purpura. A young lady with purpura, more or less recent and acute in onset, showed an almost complete absence of platelets and no thrombocyte response to the adrenalin test. There was, however, marked evidence of bone-marrow activity, exemplified in a leukocytosis of 30,000 and a reticulocytosis of 57 per cent. The spleen was normal in size and nonpalpable, and after removal, showed no microscopic evidence of endothelial or clasmotocytic hyperplasia. Within twenty-four hours of the last critical relapse to 600,000 erythrocytes, and after two emergency blood transfusions totaling 1100 cc, removal of the spleen was successfully accomplished. The platelets reappeared immediately in the circulation on the day of operation and convalescence was prompt and uneventful. All medical measures, including repeated blood transfusions had failed during the sixteen days of hospital observation, the condition on two occasions having become critical due to excessive blood loss. The behavior of the platelets suggests that, following splenectomy, the removal of the phagocytic clasmotocytes with this organ immediately released to the circulation those units which the bone marrow had been producing and that the secondary rise later may have been due to the increased megakaryocytic activity following elimination of some splenic inhibitory effect. This patient has remained well with high thrombocyte levels at all times during the past three years. One year after splenectomy, a normal baby was delivered at term after an uneventful pregnancy, but the platelets in the infant were definitely low, 150,000 to 200,000 per cubic millimeter. The study is being continued.

The thrombocytosis, described by Krumbhaar, Evans and others, which follows splenectomy has received striking and complete confirmation in our series of patients. In the majority of cases the blood platelets rose to levels well above 1,000,000 per cubic millimeter, and only once was there a failure of the thrombocytes to show a

marked sustained elevation over the preoperative control period, and in this patient the purpuric symptoms and signs were eliminated. Moreover, the blood platelets in all patients before splenectomy were definitely reduced below normal (710,000 per cubic millimeter), according to the method used for their estimation in this study. There can be no doubt as to the inhibitory effect of the spleen on thrombocytes, this is a physiologic function which, under certain abnormal circumstances, becomes pathologic and presents in greater or lesser degree a complication demanding careful consideration.

#### CONTRAINDICATIONS TO SPLENECTOMY

In our studies it has seemed that in the leukemias and in polycythemia vera the splenomegaly which occurs is a protective response and that in such cases splenectomy is distinctly contraindicated. In sickle-cell anemia there is some difference of opinion among clinical investigators, but in our clinic, improvement has never been observed following removal of the spleen in this disease, and in 2 cases there occurred the post-operative precipitation of fatal acute hemoclastic crises.

Even where a disease exists which has been proved to be benefited by splenectomy, it is essential to analyze each problem individually and to select the time and the circumstances, where possible, which will give each patient the optimum chance for recovery.

The spleen is an important organic unit in the hemolytopoietic functioning of the mammalian body, and its pathologic physiology must be understood both to avoid unnecessary or even harmful removal and to accomplish its occasional lifesaving excision.

PAPERS FROM THE FAULKNER HOSPITAL

A FIFTEEN-YEAR REVIEW OF OBSTETRICS AT THE FAULKNER HOSPITAL\*

JAMES R TORBERT, M.D.† AND ROBERT M SMITH, M.D.‡

BOSTON

ON August 8, 1917, the present maternity unit of the Faulkner Hospital was opened, and 133 babies were born in the following year. In 1937, with practically the same equipment, there were 534 births. During the early years the major percentage of cases were delivered by Boston obstetricians, but soon the hospital was used more and more by general practitioners of the adjacent district, and these men now do the majority of the obstetrics.

The obstetric service has a wing separate from the rest of the hospital, with a regular capacity of twenty-four beds and an overflow capacity of thirty-one. There are two large nurseries and a room for premature infants. The obstetric staff is headed by the chief of the department and three assistants. The other members are divided into two classes. Class A are men specially trained in obstetrics, while Class B are those who have not had special training and for whom the chief obstetrician and his associates have formulated cer-

tain restrictions in operative obstetrics, consultations being required in difficult cases. These restrictions are set forth in a precedent book, a copy of which is on the obstetric ward. This is a reference book in which is set forth a plan of treatment for all types of obstetric cases.

During the last fifteen years, 6052 babies have been delivered at the Faulkner Hospital. Of these the percentages of normal deliveries were 48.5, 43.1 and 42.9, respectively, in the successive five-year periods. This slight decrease has occurred in spite of our effort to increase the number of normal deliveries, an objective which we consider to be essential in reducing maternal as well as fetal morbidity and mortality. It is our belief that intelligent use of medication increases the possibility of normal delivery and that all patients in labor should have the benefit of some method of analgesia.

As analgesics, the barbiturate derivatives, Sodium Amytal (up to 18 gr.) and Nembutal (up to 10

TABLE 1 Statistical Summary

tain restrictions in operative obstetrics, consultations being required in difficult cases. These restrictions are set forth in a precedent book, a copy of which is on the obstetric ward. This is a reference book in which is set forth a plan of treatment for all types of obstetric cases.

There are three house officers at the Faulkner Hospital, and each has 10 to 15 deliveries during his four month period on the obstetric service. It is the aim to provide sufficient experience and instruction during this period so that a man may start general practice. If he is to specialize in obstetrics it is, of course, necessary for him to have additional training in a maternity hospital.

Because the organization of the obstetric service at the Faulkner Hospital is unique and because we believe that the publication of the results of

gr.), in divided doses, are used. Scopolamine or morphine subcutaneously, chloral hydrate orally, and ether or paraldehyde rectally are frequently combined with the barbiturates.

FORCEPS DELIVERIES

It is believed that the proper use of a low forceps is indispensable in the practice of good obstetrics, but that its use should not be routine. The earlier recognition of posterior positions has removed one of the commonest causes of the difficult forceps deliveries that resulted in extensive perineal lacerations and birth injuries to the babies. Episiotomy is advised in all forceps deliveries in primiparas, and traction rods are recommended only to bring a low mid-head onto the floor of the perineum. The use of high forceps is mentioned only to condemn the maneuver as one that is practically obsolete, while internal podalic version still has an occasional place in operative obstetrics.

From the Faulkner Hospital, Boston.  
†Chief obstetrician, Faulkner Hospital.  
‡House officer, Faulkner Hospital.

## BREECH DELIVERIES

In the ten years from 1924 to 1934 there were 102 breech deliveries with 12 infant deaths, mortality of 12 per cent. This compares favorably with the average rates of from 6 to 32 per cent mentioned in textbooks<sup>1</sup>. The infant mortality in primiparas is considerably higher than that in multiparas, in the latter the mortality should be negligible. The use of medication during labor has materially helped these cases, allowing full dilatation of the os and descent of the breech into the outlet. The chief danger in manual extraction is damage to the nerve plexuses of the arms and spinal cord from irregular and too strenuous traction. In many cases the patient will deliver normally. In others, intelligent suprapubic pressure simplifies the delivery. In primiparous cases it is advisable to use episiotomy, with forceps on the aftercoming head. These steps appreciably reduce the incidence of damage to the fetal vertebrae and cord.

## CESAREAN SECTIONS

We regard our incidence of cesarean section as too high and look with disfavor on the increasing percentage. The rates in the three successive five-year periods are 0.3, 3.4 and 8.0 per cent respectively. The average for the fifteen-year period is 4.3 per cent, or 1 in every 23 cases. In forty-five hospitals in Massachusetts the incidence in 1937 varied from 1 in 4 cases to 0 in 209 cases, with an average of 1 in 34 cases<sup>2</sup>. At the Faulkner Hospital the types of operation used were classical,

We submit the indications for cesarean section (Table 2) as stated on the record charts with the

belief that some are open to criticism. In this hospital only 3 patients have had normal pelvic deliveries following previous cesarean section. We are certain that careful study of these cases would have resulted in an increased number of pelvic deliveries. Diabetic patients are being submitted to cesarean section routinely by one of our staff in an effort to prevent late fetal death in utero, to date there have been 11 cases, with no maternal deaths and but 1 fetal death. In all 263 sections there have been 3 maternal deaths, a mortality rate of 1.1 per cent. These cases will be subsequently discussed.

## MATERNAL DEATHS

Of all statistics, those having to do with maternal deaths rank as the most important in obstetrics, and we are pleased to find on our records only 14 deaths in 6052 deliveries during the past fifteen years, a mortality rate of 2.3 per 1000. Cases of abortion are not included in this list. These figures are far below state and national averages and compare favorably with figures of other hospitals, as is shown in Table 3. It should be pointed out that the Faulkner Hospital serves a small community and keeps in relatively close contact with the local physicians, hence the incidence of neglected patients is lower than that of hospitals covering large districts, this naturally exerts a favorable effect on the number of maternal deaths.

TABLE 3 *Maternal Deaths*

HOSPITAL OR REGION	YEAR OR YEARS	NO. OF DELIVERIES	MATERNAL DEATHS PER 1000 DELIVERIES
Faulkner Hospital	1924-39	6052	2.3
Boston Lying in <sup>3</sup>	1935	2728	3.6

Massachusetts <sup>5</sup>	1923-38	1 135 715	5.5
United States <sup>6</sup>	1923-38		6.0

The 14 fatal cases can be summarized as follows:

*Case 1* The patient entered with a temperature of 105°F and died 5 days later of bronchopneumonia.

*Case 2* Lobar pneumonia developed after delivery, and death occurred in 4 days.

*Case 3* Normal delivery was followed by a normal pulse and temperature for 8 days. Then there were 6 days with symptoms of a mild phlebitis, and sudden death from pulmonary embolism on the 15th day.

*Case 4* Premature separation of the placenta occurred. After pelvic delivery the patient went into shock and died while being transfused. Incompatibility of blood was thought to be the cause of death.

*Case 5* The patient died of bilateral bronchopneumonia with peritonitis.

*Case 6* Normal delivery was followed by surgical shock. The patient was transfused but died 12 hours after delivery. Autopsy showed no cause of death.

*Case 7* After normal delivery and 13 days of uneventful convalescence, the patient suddenly died of pulmonary embolism on getting up for the first time.

*Case 8* The patient had severe cardiac disease and died 12 hours after delivery.

*Case 9* Low-forceps delivery was followed by hemorrhage, shock and death. No rupture of the uterus or cervical laceration could be found.

*Case 10* The patient had fulminating eclampsia, death occurred 13 hours post partum.

*Case 11* A repeat cesarean section was performed, with elective appendectomy. Puerperal infection developed and led to death in 14 days.

*Case 12* Pregnancy was complicated by toxemia and toxic cardiac dilatation. The patient underwent cesarean section and died of pulmonary congestion 15 minutes after completion of the operation.

*Case 13* Cesarean section was performed for disproportion. Peritonitis and septicemia developed, ending with death 13 days post partum.

*Case 14* The patient developed agranulocytic angina and died 6 days post partum.

Three patients died from postpartum hemorrhage and shock during the first two periods covered by this paper. Since then, with the improved knowledge of the mechanism of shock and the technic of blood transfusion, these accidents have been avoided. Appendectomy at the time of a cesarean section, as in Case 11, is a questionable

procedure. All elective surgical procedures at such a time should be avoided.

#### INFANT DEATHS

By an infant death is meant the death of any infant who, after birth, had evidence of heart or

lung action. It was difficult to compile these statistics for the first ten-year period of this study, due to incomplete histories of pregnancy and delivery, but the records for the last five-year period were fairly complete, due primarily to the revised labor forms which had to be filled out by the attending physician before he left the hospital.

There were 80 infant deaths during the fifteen years, 1923-1938, a rate of 13 per 1000 births, which compares favorably with the Massachusetts figures for 1923-1938 of from 43 to 91 and United States figures for the same period of from 54 to 73.<sup>5</sup>

Prematurity ranks first in cause of both prenatal and postnatal infant deaths (Table 4). In defining prematurity we take into consideration both the weight and the date of expected delivery. An infant under 5 pounds in weight or born during the first six months of pregnancy falls in this group, and in case of death, prematurity may frequently be listed as the sole cause. It is considered improbable that infants over 5 pounds in weight or beyond the seventh month of gestation die of immature development, and other causes should be found.

#### STILLBIRTHS

A stillborn baby was considered to be one that was dead before or on delivery. There were 135 stillbirths in 6052 deliveries. As will be seen from Table 5, the majority of cases were delivered by

TABLE 5 *Methods of Delivery in Cases with Stillbirths*

methods other than that of normal delivery. In addition to the technic of delivery, the prenatal care of the mother had a strong bearing on the incidence of stillbirths. Many of the cases had maternal complications such as toxemia of pregnancy, placenta previa, premature separation of the placenta, diabetes, and so forth, and we wish to emphasize the importance of immediate hospitalization of such cases and the need for the aid of an expert consultant.

#### SUMMARY

An outline of the organization of the obstetric service of the Faulkner Hospital is presented, together with a summary of the results obtained in this department during the past fifteen years.

This resume demonstrates that, while the mortality rates are satisfactorily low, there are some

## BREECH DELIVERIES

In the ten years from 1924 to 1934 there were 102 breech deliveries with 12 infant deaths, mortality of 12 per cent. This compares favorably with the average rates of from 6 to 32 per cent mentioned in textbooks<sup>1</sup>. The infant mortality in primiparas is considerably higher than that in multiparas, in the latter the mortality should be negligible. The use of medication during labor has materially helped these cases, allowing full dilatation of the os and descent of the breech into the outlet. The chief danger in manual extraction is damage to the nerve plexuses of the arms and spinal cord from irregular and too strenuous traction. In many cases the patient will deliver normally. In others, intelligent suprapubic pressure simplifies the delivery. In primiparous cases it is advisable to use episiotomy, with forceps on the aftercoming head. These steps appreciably reduce the incidence of damage to the fetal vertebrae and cord.

## CESAREAN SECTIONS

We regard our incidence of cesarean section as too high and look with disfavor on the increasing percentage. The rates in the three successive five-year periods are 0.3, 3.4 and 8.0 per cent respectively. The average for the fifteen-year period is 4.3 per cent, or 1 in every 23 cases. In forty-five hospitals in Massachusetts the incidence in 1937 varied from 1 in 4 cases to 0 in 209 cases, with an average of 1 in 34 cases<sup>2</sup>. At the Faulkner Hospital the types of operation used were classical,

We submit the indications for cesarean section (Table 2) as stated on the record charts with the

belief that some are open to criticism. In this hospital only 3 patients have had normal pelvic deliveries following previous cesarean section. We are certain that careful study of these cases would have resulted in an increased number of pelvic deliveries. Diabetic patients are being submitted to cesarean section routinely by one of our staff in an effort to prevent late fetal death in utero, to date there have been 11 cases, with no maternal deaths and but 1 fetal death. In all 263 sections there have been 3 maternal deaths, a mortality rate of 1.1 per cent. These cases will be subsequently discussed.

## MATERNAL DEATHS

Of all statistics, those having to do with maternal deaths rank as the most important in obstetrics, and we are pleased to find on our records only 14 deaths in 6052 deliveries during the past fifteen years, a mortality rate of 2.3 per 1000. Cases of abortion are not included in this list. These figures are far below state and national averages and compare favorably with figures of other hospitals, as is shown in Table 3. It should be pointed out that the Faulkner Hospital serves a small community and keeps in relatively close contact with the local physicians, hence the incidence of neglected patients is lower than that of hospitals covering large districts, this naturally exerts a favorable effect on the number of maternal deaths.

TABLE 3 *Maternal Deaths*

HOSPITAL OR REGION	YEAR OR YEARS	NO OF DELIVERIES	MATERNAL DEATHS PER 1000 DELIVERIES
Faulkner Hospital	1924-39	6052	2.3
Boston Lying in <sup>3</sup>	1935	2728	3.6
Chicago Lying In <sup>4</sup>	1935-36	2394	2.1
Massachusetts <sup>5</sup>	1923-38	1 135 715	5.5
United States <sup>6</sup>	1923-38		6.0

The 14 fatal cases can be summarized as follows:

**Case 1** The patient entered with a temperature of 105°F and died 5 days later of bronchopneumonia.

**Case 2** Lobar pneumonia developed after delivery, and death occurred in 4 days.

**Case 3** Normal delivery was followed by a normal pulse and temperature for 8 days. Then there were 6 days with symptoms of a mild phlebitis, and sudden death from pulmonary embolism on the 15th day.

**Case 4** Premature separation of the placenta occurred. After pelvic delivery the patient went into shock and died while being transfused. Incompatibility of blood was thought to be the cause of death.

**Case 5** The patient died of bilateral bronchopneumonia with peritonitis.

**Case 6** Normal delivery was followed by surgical shock. The patient was transfused but died 12 hours after delivery. Autopsy showed no cause of death.

and he added 2 more. Since then there have been sporadic reports of a handful of cases by Black,<sup>4</sup> <sup>5</sup> Stearns,<sup>6</sup> McGuire and McGuire<sup>7</sup> and others. The total number can be said to come to less than 70. In 1937 Phaneuf<sup>8</sup> stated that he had encountered 38 cases of large hernia of the cul-de-sac of Douglas, but examination of the 5 cases described by him in this and a previous report<sup>9</sup> shows that most of these were not true posterior vaginal hernias but rather what Miles defined as elytrocele.

#### REPORT OF A CASE

A 50-year-old housewife first admitted to the Faulkner Hospital in January, 1930, had suffered backache, bearing-down pain and prolapse of the uterus since the birth of her only child 22 years previously. She had undergone two operations for suspension, the last one in 1920. Both suspensions gave way within 6 months after returning to work. Catamenia had ceased 4 months previous to admission, without further menopausal symptoms.

The past history was not remarkable except for two operations for hyperthyroidism, in 1909 and in 1920.

Physical examination revealed a large, healthy woman with negative general findings except healed thyroid and median suprapubic scars. The perineum and cervix were badly lacerated and there was a marked prolapse of the uterus, the cervix extending to the vulva.

At operation, the cervix was amputated and the perineum repaired. The abdomen was opened, and the uterus was found to be retrocessed and to contain one small fibroid on the posterior surface. This fibroid was removed and the uterus firmly affixed to the anterior abdominal wall after denuding the fundus. (There was no evidence at this time of any break in the posterior cul-de-sac.) The wound was closed without drainage and the patient made an excellent convalescence.

In 1933 a check up revealed no evidence of return of the prolapse or any relaxation of the perineum.

The patient re-entered the hospital in May, 1937, complaining of pain in the back and right side and a sense of pulling down which she had noticed for 2 years. In the few months before admission she had felt some structure protruding from the vagina.

General physical findings were normal. Pelvic examination revealed a small, atrophic uterus attached well up in the anterior position. The perineum was normal anteriorly. Rectal examination showed what was interpreted as a prolapse of the rectum through the upper part of the posterior vaginal wall. The preoperative diagnosis was rectocele.

At operation, the perineum was denuded, exposing the protruding mass. With a finger in the rectum careful dissection showed that this was not a rectocele but a hernial sac with a narrow neck, whose origin lay just below the cervix. The sac contained small bowel, apparently ileum. This was reduced, the sac tied off at the neck and removed. The uterosacral ligaments were then sutured together in front of the stump. Excess mucous membrane was removed and the wound closed after bringing the peritoneal bed together a little more completely.

The patient felt immediately relieved of bearing-down pain, but right flank pain persisted during convalescence, gradually diminishing as strength was regained. On examination 18 months later the posterior vaginal wall was found to be in good condition with no evidence of recur-

rence of the hernia. A cystocele had developed, however, entirely independent of any effect of previous operations, and necessitated a simple anterior colporrhaphy.

This case illustrates many of the features of the typical posterior vaginal hernia. The symptoms are a bearing-down sensation and the feeling of a mass in the vagina. In cases with incarceration or strangulation of the intestine in the hernial sac, symptoms of obstruction are also present. The correct preoperative diagnosis could have been made here if the upper part of the vaginal floor had been examined more carefully both by vagina and rectum with this condition in mind. Because the previous rectocele repair had remained in good condition, there was not the marked bulging into the perineum which is often seen. A gurgling in the intestine in the hernial sac and collapse of the sac by reduction of its contents into the abdominal cavity are diagnostic signs which differentiate posterior vaginal hernia and rectocele or vaginal cyst. Differentiation from uterine prolapse should be difficult only when the two conditions are found together. This situation, however, is not infrequent.

In the present case the preceding prolapse of the uterus, necessitating three operations for suspension, the rectocele and the later cystocele exemplify the predisposing factor of weakness of the pelvic tissues. Parenthetically we might postulate that bringing the retrocessed uterus forward and affixing it to the anterior abdominal wall aided the formation of the hernia by allowing the intestine to press directly down on the bottom of the cul-de-sac of Douglas. As has been stated, no defect in the cul-de-sac was noted at the time of the abdominal operation.

The type of repair described here is the method devised by Ward<sup>10</sup>. Phaneuf<sup>8</sup> uses this for uncomplicated hernia, but when adhesions are present he advises the Moschcowitz intra-abdominal operation,<sup>11</sup> which was originated for the cure of prolapse of the rectum. This obliterates the cul-de-sac from above by a series of purse-string sutures. Such a method would seem to be the logical and necessary procedure in cases so complicated as to need abdominal operation.

#### SUMMARY

Posterior vaginal hernia is a rare condition but probably occurs more often than is recognized.

It may frequently be the cause of unsuccessful repairs of rectocele.

The true posterior vaginal hernia is a definite peritoneal sac with a neck and must be differentiated from elytrocele, in which there is a prolapse of the uterus accompanied by a bulging of ab-

aspects of the work that are open to improvement. Furthermore, it points out exactly how these changes are to be made.

## POSTERIOR VAGINAL HERNIA

FRANCIS F CARY, MD,\* AND EDWARD L YOUNG, M.D.†

BOSTON

THIS paper is presented in order to call attention to a rather rare gynecologic condition simulating rectocele and uterine prolapse, which is frequently undiagnosed preoperatively and is occasionally unrecognized at operation for repair of the pelvic floor. It is often the cause of recurrence of what is apparently a simple rectocele.

Miles<sup>1</sup> has classified all protrusions of peritoneum into the pelvic tissues as pelvic hernias, and has subdivided them into the pudendal, perineal and vaginal types. In this paper the first two will not be discussed. Vaginal hernias are either anterior or posterior depending on whether they protrude between the bladder and vagina or the vagina and rectum. Posterior vaginal hernia has also been called in the literature hernia of the cul-de-sac of Douglas, enterocele and high rectocele, but these names are also used in describing conditions other than true vaginal hernia. A true posterior vaginal hernia is a definite peritoneal sac pushing down from the pouch of Douglas in the midline and dissecting between the rectum and vagina. The neck of the sac is located between the uterosacral ligaments just behind the top of the vagina, and through this, abdominal contents pass to form a mass which may bulge out through the vulva when the patient strains down.

Rectocele and uterine prolapse frequently accompany this condition but should be differentiated from it. Particularly is this true when there is a massive prolapse of the uterus and vaginal floor caused by an abnormally deep cul-de-sac. Reports of cases of vaginal hernia in the literature are confusing on this point. Miles<sup>1</sup> has clarified the issue as follows:

Some authors have classified both cystocele and rectocele as vaginal herniae, while by far the greater number of cases reported, on close analysis, turn out to be cases of prolapsus or descensus of the uterus accompanied by a bulging of abdominal contents into a distended cul-de-sac. In [this condition] there is no true vaginal hernial sac and no ring or

aperture through which the viscera herniate. The uterus descends because of stretched and attenuated cardinal and uterosacral ligaments, the cul-de-sac is enlarged and there is really a descent of the floor of the pelvis. This condition is properly termed clytocele or vaginal enterocele.

Jones<sup>2</sup> defined three types of deep cul-de sac and described the relation of each to the strength of the pelvic fascia. The first he called a congenital type in which the peritoneum dips into the pelvis, is smooth and closely lines the organs, flattening the rectum posteriorly and pushing forward the back of the uterus and cervix. The fascia in this group is of poor quality. The second type is also large and deep but the peritoneum lies in redundant folds over the pelvic viscera, which are not displaced by it. This is the acquired type, and the pelvic fascia is of fair strength. In the third type, which is rare, the fascia is generally good but there is a small opening between the vagina and rectum reaching from the posterior cul-de-sac, in normal position, down to the levators and usually causing a vaginal protrusion. It suggests a protrusion through a small defect in the fascia. The first two types are responsible for massive prolapse of the rectum or uterus, whereas the third group represents the basis for the true posterior vaginal hernia.

There is general agreement that three main factors lead to the development of a vaginal hernia: predisposition of weakness of the pelvic floor such as alluded to above and also accidents of parturition, intra-abdominal pressure of pregnancy, ascites or tumors, and sudden trauma such as childbirth, straining and lifting of weights. These are local applications of principles underlying all hernias.

Garengot reported a case of vaginal hernia two hundred years ago, and Sir Astley Cooper described the condition in his monograph on hernia in 1804, but actual numerical reports are few. In the literature up to 1932 Bueermann<sup>3</sup> found 76 cases sufficiently well defined to be called vaginal hernias. Of these, 56 were of the posterior type,

and he added 2 more. Since then there have been sporadic reports of a handful of cases by Black,<sup>4</sup> Stearns,<sup>6</sup> McGuire and McGuire<sup>7</sup> and others. The total number can be said to come to less than 70. In 1937 Phaneuf<sup>8</sup> stated that he had encountered 38 cases of large hernia of the cul-de-sac of Douglas, but examination of the 5 cases described by him in this and a previous report<sup>9</sup> shows that most of these were not true posterior vaginal hernias but rather what Miles defined as elytrocele.

#### REPORT OF A CASE

A 50-year-old housewife first admitted to the Faulkner Hospital in January, 1930, had suffered backache, bearing-down pain and prolapse of the uterus since the birth of her only child 22 years previously. She had undergone two operations for suspension, the last one in 1920. Both suspensions gave way within 6 months after returning to work. Catamenia had ceased 4 months previous to admission, without further menopausal symptoms.

The past history was not remarkable except for two operations for hyperthyroidism, in 1909 and in 1920.

Physical examination revealed a large, healthy woman with negative general findings except healed thyroid and median suprapubic scars. The perineum and cervix were badly lacerated and there was a marked prolapse of the uterus, the cervix extending to the vulva.

At operation, the cervix was amputated and the perineum repaired. The abdomen was opened, and the uterus was found to be retrocessed and to contain one small fibroid on the posterior surface. This fibroid was removed and the uterus firmly affixed to the anterior abdominal wall after denuding the fundus. (There was no evidence at this time of any break in the posterior cul-de-sac.) The wound was closed without drainage and the patient made an excellent convalescence.

In 1933 a check up revealed no evidence of return of the prolapse or any relaxation of the perineum.

The patient re-entered the hospital in May, 1937, complaining of pain in the back and right side and a sense of pulling down which she had noticed for 2 years. In the few months before admission she had felt some structure protruding from the vagina.

General physical findings were normal. Pelvic examination revealed a small, atrophic uterus attached well up in the anterior position. The perineum was normal anteriorly. Rectal examination showed what was interpreted as a prolapse of the rectum through the upper part of the posterior vaginal wall. The preoperative diagnosis was rectocele.

At operation, the perineum was denuded, exposing the protruding mass. With a finger in the rectum careful dissection showed that this was not a rectocele but a hernial sac with a narrow neck, whose origin lay just below the cervix. The sac contained small bowel, apparently ileum. This was reduced, the sac tied off at the neck and removed. The uterosacral ligaments were then sutured together in front of the stump. Excess mucous membrane was removed and the wound closed after bringing the peritoneal bed together a little more completely.

The patient felt immediately relieved of bearing-down pain, but right flank pain persisted during convalescence, gradually diminishing as strength was regained. On examination 18 months later the posterior vaginal wall was found to be in good condition with no evidence of recur-

rence of the hernia. A cystocele had developed, however, entirely independent of any effect of previous operations, and necessitated a simple anterior colporrhaphy.

This case illustrates many of the features of the typical posterior vaginal hernia. The symptoms are a bearing-down sensation and the feeling of a mass in the vagina. In cases with incarceration or strangulation of the intestine in the hernial sac, symptoms of obstruction are also present. The correct preoperative diagnosis could have been made here if the upper part of the vaginal floor had been examined more carefully both by vagina and rectum with this condition in mind. Because the previous rectocele repair had remained in good condition, there was not the marked bulging into the perineum which is often seen. A gurgling in the intestine in the hernial sac and collapse of the sac by reduction of its contents into the abdominal cavity are diagnostic signs which differentiate posterior vaginal hernia and rectocele or vaginal cyst. Differentiation from uterine prolapse should be difficult only when the two conditions are found together. This situation, however, is not infrequent.

In the present case the preceding prolapse of the uterus, necessitating three operations for suspension, the rectocele and the later cystocele exemplify the predisposing factor of weakness of the pelvic tissues. Parenthetically we might postulate that bringing the retrocessed uterus forward and affixing it to the anterior abdominal wall aided the formation of the hernia by allowing the intestine to press directly down on the bottom of the cul-de-sac of Douglas. As has been stated, no defect in the cul-de-sac was noted at the time of the abdominal operation.

The type of repair described here is the method devised by Ward.<sup>10</sup> Phaneuf<sup>8</sup> uses this for uncomplicated hernia, but when adhesions are present he advises the Moschowitz intra-abdominal operation,<sup>11</sup> which was originated for the cure of prolapse of the rectum. This obliterates the cul-de-sac from above by a series of purse-string sutures. Such a method would seem to be the logical and necessary procedure in cases so complicated as to need abdominal operation.

#### SUMMARY

Posterior vaginal hernia is a rare condition but probably occurs more often than is recognized.

It may frequently be the cause of unsuccessful repairs of rectocele.

The true posterior vaginal hernia is a definite peritoneal sac with a neck and must be differentiated from elytrocele, in which there is a prolapse of the uterus accompanied by a bulging of ab-

dominal contents into a distended cul-de-sac of Douglas

Only 70 cases of true posterior vaginal hernia are to be found in the literature

An additional case is reported which exemplifies many of the typical aspects of symptomatology, etiology, differential diagnosis and treatment of this condition

330 Dartmouth Street.

## CASE RECORDS OF THE FAULKNER HOSPITAL

### Antemortem and Postmortem Records as Used in Monthly Clinicopathological Conferences

Directed by J BEACH HAZARD, M.D

#### CASE 6389

##### PRESENTATION OF CASE

*First Admission* A sixty-four-year-old, American housewife was admitted complaining of nausea and vomiting

Three years preceding entry she began to have attacks of upper abdominal distress Vomiting frequently occurred after eating the first two or three mouthfuls of any meal, but after this she could usually return and finish eating without further symptoms At times she was free from these attacks for several months Before entry, an x-ray examination of the upper gastrointestinal tract showed abnormal activity of the esophagus, but no delay in the passage of barium, no lesion was demonstrated The stomach and duodenum were normal A Graham test was negative Flat abdominal films were negative, except for a prominent splenic shadow The spine showed evidence of hypertrophic arthritis Two weeks before entry there had been an acute onset of abdominal distress after eating a rich meal For several days following this she noticed marked weakness, and examination at the end of this time revealed generalized abdominal distention with increased peristalsis but no tenderness During this day two loose bowel movements occurred, which were accompanied by generalized abdominal cramps About a week preceding admission, definite upper abdominal tenderness was noted, and the blood white-cell count was 10,000 Her nausea continued and on one occasion she stated that she had vomited material of coffee-ground character

The basal metabolic rate was determined two years before entry and was found to be -13 per

cent, and she had been given thyroid extract but had voluntarily omitted it some months before admission Her general health had otherwise been good There had been no operations She had had the usual diseases of childhood but no diphtheria or scarlet fever The menopause had occurred about two years preceding admission Her weight had been constant

The family history revealed that her mother died at the age of forty-eight of cancer Her father died of hypertension Three siblings were living and well One aunt died of cancer

Physical examination revealed an obese individual with a dry skin, which was thickened and firm in texture The pupils were equal and reacted regularly The tongue was clean Her throat appeared somewhat injected There was no general enlargement of the lymph nodes Examination of the lungs was negative The heart was slightly enlarged, and there was a soft systolic murmur, the sounds were regular The abdomen was distended and hyperresonant, and presented marked peristalsis, there was definite spasm and tenderness and a questionable mass in the right upper quadrant The liver and spleen were not palpable The extremities were negative.

The temperature was 98.4°F, the pulse rate 84, and the respirations 20 The blood pressure was 178 systolic, 88 diastolic

The urine was negative except for a specific gravity of 1.038 The blood white-cell count was 12,700 with 77 per cent polymorphonuclears The red-cell count was 5,100,000 with a hemoglobin of 100 per cent (Sahl) The blood smear appeared normal A stool specimen was brownish green, with a 1+ benzidine test

An x-ray examination made one week after admission showed a normal esophagus and stomach

There was some undue irritability of the duodenum and sigmoid colon. The Graham test was again negative.

During her stay in the hospital the patient's temperature showed an afternoon rise to 99 or 100°F. The tenderness in the right upper quadrant was present intermittently, and at the end of the first week she had some tenderness to the left of the epigastrium on deep pressure. There was soreness across the back, which at times was severe, and also a variable amount of abdominal distress, particularly after the evening meal. Vomiting occurred once or twice daily, and at one time amounted to 800 cc. The vomitus contained no gross blood. Sodium bicarbonate had been administered in 10-gr doses with little relief, and  $\frac{1}{4}$  gr of morphine was given almost daily.

The white-cell count remained between 10,000 and 12,000. Ten successive stool examinations showed the specimens to be yellowish-brown, with only two showing a positive benzidine test.

Abdominal tenderness at the time of discharge, two weeks after admission, had almost entirely disappeared.

*Second Admission* (two years later) The patient was readmitted because of vomiting.

She had continued to vomit the first two or three mouthfuls of almost every meal and then to eat normally. About two weeks before entry she began to have epigastric distress, coming on about two hours after meals and usually relieved by soda. There was also low precordial pain, which radiated to the left shoulder and down the left arm and was brought on by exertion. The original attack of pain followed a heavy meal and necessitated her sitting down for some time. She was placed on a fairly strict Sippy regime, with immediate relief for forty-eight hours, followed by a recurrence of symptoms.

Physical examination showed a pale woman in some distress, lying quietly in bed. The heart sounds were regular and of good quality, with a systolic murmur at the apex and an accentuated A<sub>2</sub>. The abdomen was distended and tympanitic, with slight tenderness in right and left upper quadrants, but no mass or spasm. Ophthalmoscopic examination showed moderate sclerotic changes of the retinal vessels, but no exudate or hemorrhage. Physical examination was otherwise negative.

The temperature was 99.2°F., the pulse rate 72, and the respirations 24. The blood pressure was 120 systolic, 80 diastolic.

Urinalysis showed a slight trace of albumin and a very rare erythrocyte. The blood white-cell count

was 11,550 with 78 per cent polymorphonuclears, and the red-cell count 5,000,000 with a hemoglobin of 101 per cent (Sahli). A nonprotein nitrogen was 39 mg per 100 cc., and a blood sugar 129 mg. A blood Hinton test was negative.

A gastrointestinal series disclosed a dilated stomach, which was almost completely obstructed. Six hours after the meal only a small amount of barium was seen scattered throughout the small bowel. The obstruction was beyond the sphincter, which was well differentiated. During the examination just enough barium entered the duodenum to identify the base of the cap. The rest of the gastrointestinal tract showed no abnormality.

During her stay she vomited on several occasions, two of the specimens examined showing a 1+ benzidine test. She had been admitted chiefly for x-ray studies and was discharged seventy-two hours after admission.

*Final Admission* (fifteen months later) The patient was readmitted because of vomiting.

Since the previous admission she had been at home on a strict Sippy diet. She continued to vomit the first portion of many meals and occasionally after meals, but there was little distress. At times there was precordial pain with radiation down the left arm, usually relieved by nitroglycerin. She had gained weight. X-rays taken about one year previous to admission showed a constricted area of irregular contour in the esophagus opposite the ninth and tenth dorsal vertebral bodies and measuring 4 cm in length. The first portion of the duodenum showed spasm, but the stomach emptied at a normal rate. Three months before entry she was put to bed because symptoms of abdominal distress became more severe and were accompanied by pain in the left upper quadrant. For about a month preceding entry severe retching and vomiting occurred, sometimes with the production of blood-streaked material. X-ray films taken two months preceding admission showed the esophagus to measure 3 cm in width above the constricted zone. The mucosal pattern appeared to continue through the defect. The stomach was small and hypertonic, and the duodenal cap showed constant deformity but no crater. Pain in the left upper quadrant continued, and a palpable mass was noted in that vicinity. She was admitted because of the increased intensity of symptoms.

The patient's color appeared good, and the skin was dry. The left border of the heart was percussed at the nipple line, there was a blowing systolic murmur, but no diastolic murmur, and A<sub>2</sub> was slightly greater than P<sub>2</sub>. The abdomen was soft and symmetrical. There were points of

tenderness under the left costal margin and in the right lower quadrant. In the latter region there was a small indefinite mass, which could be moved. The spleen was thought to be palpable, but the liver edge was not felt.

The temperature was 98°F, the pulse rate 67, and the respirations 14. The blood pressure was 120 systolic, 68 diastolic.

Urinalysis showed a slightest possible trace of albumin and sugar, and the sediment contained frequent erythrocytes. Acetone was present, but no diacetic acid. The blood white-cell count was 5000 with 60 per cent polymorphonuclears, and the red-cell count 3,600,000 with a hemoglobin of 75 per cent (Sahli). The smear appeared normal. A blood sugar was 153 mg per 100 cc. A stool on the second day after entry was light brown and gave a 3+ benzidine test.

After admission the patient was kept quietly in bed and given intravenous glucose once or twice daily. Water in sips by mouth was attempted, but promptly caused vomiting. The vomitus at one examination showed a free hydrochloric acid of 40 units. Seven specimens showed from 2+ to 4+ benzidine tests. The mass in the right lower quadrant moved up to the right upper quadrant, and then disappeared. Substernal pain was sometimes relieved by nitroglycerin, but morphine was required in frequent doses. Each time she was seen by her husband or any member of her family or by her physician, nausea and vomiting were precipitated. On the twelfth day after entry a bedside film of the chest and upper abdomen, taken following the ingestion of a small amount of barium, showed most of the barium in the stomach with a small amount scattered through the lower half of the esophagus. Two centimeters above the diaphragm there was an area of narrowing of the esophagus, extending upward about 4 cm. There was no dilatation of the esophagus above. A film twenty-four hours later showed the stomach empty, and the barium scattered through the proximal colon. During the last week of stay the patient vomited dark coffee-ground material, a small nasal tube was passed into the stomach, and about 2000 cc of bloody material removed. On the seventeenth day after entry her pulse became imperceptible, and she died quietly.

#### DIFFERENTIAL DIAGNOSIS

DR WILLIAM B BREED. This patient's history extends through a period of about five years and three months, during which time she came into this hospital three times. Her symptoms were referable to the gastrointestinal tract, varied greatly from time to time, and were periodic. My first

thought is that there must have been some diffuse process which affected the esophagus, the stomach, the duodenum and perhaps other portions of the gastrointestinal tract. Her symptoms at the beginning suggest cardiospasm and possibly a diaphragmatic hernia, which later is ruled out. Then there are symptoms of pylorospasm with complete obstruction. There follows a period during which the stomach acted well, food passing readily through it. Recorded in the history and also in the physical examination is a very interesting series of observations, namely "fleeting" masses in the abdomen, first in the right lower quadrant, then in the left lower quadrant, and again in the right upper quadrant. No localized process would produce such a picture. Before defending one diagnosis I should like to ask the roentgenologist whether he can say definitely that this woman did not have esophageal varices at any time.

DR MAGNUS I SMEDAL. I never saw them.

DR BREED. In the description such a finding was not suggested. If she did have esophageal varices it might lead us toward a diagnosis of cirrhosis of the liver, or thrombosis of the splenic vein with esophageal varices. Your report makes me reasonably confident in ruling out these diagnoses.

The one diagnosis I wish to place before you for consideration is a radiosensitive tumor of the lymphoma group. This, it is true, does not explain the symptoms referable to her heart, which I believe were due to arteriosclerotic heart disease with coronary disease.

You will note that every time she came into the hospital and had x-ray studies she was better and went home for a period of months. I have heard of cases that are so sensitive to x-ray that the process will subside and allow normal function to go on, even after only diagnostic exposure. Now, is it true that she had had no x-ray treatment? Do you know how many times she was x-rayed?

DR F WILLIAM MARLOW, JR. She was x-rayed at least five times but had had no x-ray therapy.

DR BREED. She had this diffuse process in her gastrointestinal tract. I have tried to explain it on various other grounds. I do not think she had carcinoma. She lived for five and a half years and did not lose weight. From time to time her symptoms subsided without any particular form of treatment other than diet and rest. During the two years she was at home between the first and second admissions and the fifteen months between the second and third, she improved directly after she left the hospital. Of course there is no question but there was a psychogenic element here, but she did not die of psychoneurosis! Furthermore, psychoneurosis does not produce

lumps in the abdomen from time to time I should like to go over the films with Dr Smedal

DR. SMEDAL Here are representative films of several examinations

Four years before the final entry Dr Sidney L Morrison said he could find only an irritable duodenum, the rest of the gastrointestinal tract being negative We have no films from the first examination five and a half years before admission at which some irritability of the esophagus was reported Two years later she had this dilated stomach, with marked peristalsis and practically complete obstruction just at the duodenal cap The barium in the colon is the residue from a barium enema done the day before After six hours, there was almost no barium in the small bowel A film one year before final entry showed a narrowing in the lower third of the esophagus, which was persistent at all times The final film taken one year later with a portable machine after the patient had had a small amount of barium showed no obstruction at the lower end of the esophagus

DR. BREED The obstruction at the pylorus disappeared completely?

DR. SMEDAL Yes

DR. BREED Of course she could have had a duodenal ulcer which improved on a Sippy diet at home, but this transient obstruction of the pylorus I cannot understand It certainly is hard to explain on a psychogenic basis I think cancer in any portion of the gastrointestinal tract, in the pancreas or in any other place seems a remote possibility She may have had an ulcer of her duodenum, but I cannot see how an ulcer there would explain the esophageal lesion or the appearance and disappearance of masses in her abdomen I wonder if it would not be possible to find out a little more about the nature of these masses I was in doubt as to just what they were Were they hard masses? Were they movable? Were they tender?

DR. MARLOW We thought the masses were fecal

DR. BREED I cannot explain the esophageal symptoms or the x-ray picture of the esophagus on the basis of an ulcer unless she had an ulcer in her esophagus as well as in her duodenum Could you say that the defect is an ulcer of the esophagus, Dr Smedal?

DR. SMEDAL X-ray films during her hospital stay showed no esophageal lesion Dr Morrison demonstrated an esophageal lesion at an office visit several months later

DR. SIDNEY L MORRISON At the time I examined her the stricture was constant I thought there was some irritability of the esophagus It

did not look irregular enough to say that it was cancer, and yet I did not dare to say it was not cancer on a single examination At one time I wondered if there was not an extra-esophageal lesion, but I was unable to demonstrate it I said it could be a stricture or it could be cancer, and requested another examination I examined her for a long time because I could not satisfy myself that the lesion was a malignant neoplasm

DR. MARLOW Here is Dr Morrison's report at the time "There is a constricted area in the lower third of the esophagus which is rather rigid, that is, it would not dilate either with thick or thin barium There was quite a bit of cardiospasm"

DR. BREED After this examination, with considerable exposure to x-ray, did she improve?

DR. MARLOW Yes She got well enough to go abroad and to stay there from early summer up until the following Thanksgiving, when, just before going to visit some friends, she had a recurrence of symptoms that persisted practically until the time she died An x-ray film was taken two months before she died, and at that time the esophagus was dilated, measuring 3 cm in width in its middle third There was marked irregular narrowing in the lower third about 8 cm above the cardia

DR. BREED Let us take up the question of whether or not this is cancer of the esophagus Three years before her first admission the story was one referable to the esophagus, and I should think it almost inconceivable that cancer in the lower third of the esophagus could be of as long a duration as that, with periods of remission I cannot explain this on any basis other than that the lesion was some diffuse, non-epithelial tumor which may have been very sensitive to x-rays, probably a lymphoma

DR. MARLOW During the five years before her death she never had a blood count less than 5,500,000 or a hemoglobin less than 80 per cent (Sahli), and all differential counts were normal

DR. BREED That only strengthens the impression that she did not have cancer

DR. EDWARD L YOUNG I saw her two or three times in consultation with Dr Marlow The first time I thought she had gall-bladder disease and a psychoneurosis, the second time my diagnosis was duodenal ulcer with a neurosis, and the third time I believed the whole picture was psychoneurotic Since she died, the last diagnosis is undoubtedly wrong The early part of her illness might have been caused by ulcer, and the last part by cancer That would explain the symptoms as I see them

A PHYSICIAN I should like to ask Dr Breed if the fact of her vomiting after the first two or

three mouthfuls and then going back and eating a whole meal is not characteristic of hysterical vomiting, and I should also like to ask if it is possible that she might have died through starvation of psychogenic origin

DR BREED I agree that the first part of the story is very suggestive of cardiospasm of psychogenic origin. As to her death, she did bleed a good deal and they removed 2000 cc of bloody material at the end, furthermore, she had occult blood from time to time in her stools. It is true that lymphomas of the intestine do not usually bleed profusely.

DR MARLOW Dr Breed suggested a diagnosis that we did not think of during five years. She did not lose weight until a short time before she came into the hospital and that was explained because she had taken practically nothing by mouth for from three to six weeks. She would get a little relief for several days on a very strict Sippy diet, and as soon as the slightest attempt was made to increase it, she promptly obstructed and began to vomit. We went through about the same mental distress that Dr Breed has.

She died of hemorrhage, her pulse becoming gradually weaker and then suddenly stopping. I support my finding of a palpable spleen by the fact that two other people examined her and came to this same conclusion. It was also reported to be enlarged by x-ray.

I think part of the reason for the difficulty in diagnosis was the fact that she was a difficult woman from whom to obtain a history and one could not really tell whether her pain was anginal or due to a simple ulcer. Finally, after persistent questioning, a history of two definite types of pain was extracted.

#### CLINICAL DIAGNOSES

Cancer or ulcer of the esophagus  
Duodenal ulcer  
Coronary disease

#### DR BREED'S DIAGNOSES

Diffuse non-epithelial tumor of the esophagus, probably lymphoma  
Coronary disease  
Arteriosclerosis

#### PATHOLOGICAL DIAGNOSES

Chronic peptic ulcer of esophagus, with hemorrhage  
Chronic duodenal ulcers  
Healed and healing infarct of myocardium, secondary to arteriosclerotic occlusion of circumflex branch of left coronary artery and more recent arteriosclerotic and thrombotic occlusion of right coronary artery

#### PATHOLOGICAL DISCUSSION

DR J BEACH HAZARD May I first apologize for inserting such a detailed picture of the fleeting abdominal masses. My only excuse is they were described in detail in the record. They were not present at autopsy, and the assumption of their being scybala is probably correct. The defect in the esophagus was a peptic ulcer, 5 by 3 cm, it had extended to the periesophageal fat tissue but had not caused a mediastinitis. The ulceration was located just above the cardia and almost encircled the esophagus. In the ulcer bed there was a zone of extensive hemorrhage. Fresh blood was present in the esophagus, and there was 500 cc of coffee-ground fluid in the stomach. There were three duodenal ulcers adjacent to the pylorus, and 3 cm distal to these was a deep ulcer which extended through the duodenal wall, though it had not perforated into the peritoneal cavity.

To explain the pain down the arm, old and recent infarctions in the posterior wall of the myocardium were found. There was also an old occlusion of the left circumflex coronary artery, and a more recent occlusion of the right coronary artery.

Esophageal ulcers are relatively rare, and when they do occur, are often associated with gastric or duodenal ulcers. The pain is usually referred to the lower substernal region, and the lesion is often mistakenly judged to be duodenal in location.

#### CASE 6390

##### PRESENTATION OF CASE

A seventy-eight-year-old retired business man was admitted with the chief complaints of abdominal pain and diarrhea.

About nine weeks preceding entry he developed pain in the epigastrium, which was described as "pressure or gas pain" and lasted twenty-four hours. There was no vomiting. For a short time following this he felt fairly well except for occasional attacks of "gas pains." A second attack of epigastric pain occurred about eight weeks before admission and was accompanied by nausea, vomiting and a feeling of feverishness. It was followed by diarrhea. He went to bed for four weeks and felt sufficiently weak to have a nurse in attendance. During the month preceding admission he experienced occasional epigastric pain with, at times, some diarrhea. No blood was noted in the stools. The pain was said to occur occasionally about half an hour after eating but was not regular. An x-ray examination was made four weeks before entry. The gall bladder contained one gallstone (about 2.5 cm in diameter) and showed no ex-

cretion of dye The liver was of normal size A barium meal showed a negative stomach with normal emptying time There was also a slight irregularity of the duodenum, which was interpreted as probably due to adhesions There was no obstruction in the small intestine The colon showed normal motility The cecum was rather low in position, and some of the films gave evidence of pressure on the cecum Ten days later a re-examination of the large intestine with barium enema and fluoroscope showed a filling defect in the cecum on the medial aspect, which apparently extended posteriorly It was interpreted by one observer as being a mass pressing on the cecum There was no evidence of obstruction by the mass either in the ileum or the colon

The patient had always been in good health There had been no operations or injuries His family history was noncontributory

Physical examination revealed a well-developed and nourished man in generally fair condition There was no generalized enlargement of the lymph nodes Examination of the chest and lungs was negative A mass approximately 15 by 15 cm was present in the right lower quadrant of the abdomen This was slightly tender along its lower border The surface seemed smooth, with a somewhat irregular area on its inferior aspect It was partially movable Rectal examination showed a somewhat enlarged prostate.

The temperature was 97.8°F, the pulse rate 80, and the respirations 20 The blood pressure was 144 systolic, 96 diastolic

A urine specimen was of acid reaction, had a specific gravity of 1.014 and contained a slightest possible trace of albumin, no sugar, no casts, no red blood cells, 2 to 3 white blood cells per high-power field, and occasional epithelial cells The blood white-cell count was 9250 with 66 per cent polymorphonuclears, the red-cell count 4,600,000 with a hemoglobin of 83 per cent (Sahli) A smear showed slight anisocytosis and apparently normal platelets A stool specimen gave a negative benzidine test The blood nonprotein nitrogen was 38 mg per 100 cc, the blood sugar 93 mg., and the blood Hinton test negative

After admission the patient was comfortable without medication The temperature ranged from 97 to 99.5°F, and on the third day an abdominal operation was performed Examination of the abdomen under anesthesia showed the mass in the right lower quadrant to be quite movable

#### DIFFERENTIAL DIAGNOSIS

DR EDWARD L. YOUNG We have here a clean-cut picture of an elderly man who was apparently well until nine weeks before admission, and then

developed several attacks of epigastric pain and some diarrhea and came in with a mass in the right lower quadrant The latter was something definite and so must be labeled What data are there to aid us? The description of the pain will fit almost anything that is involving the mesentery of the small intestine in the right lower quadrant I believe the fact the pain was epigastric means that the mass involved the peritoneum or mesentery in the neighborhood of the small bowel and that it was not an intrinsic cecal lesion Diarrhea merely indicates irritation in the bowel We see it occasionally in inflammations and at times with neoplasms Nevertheless, I believe that if there was an intrinsic neoplasm of this size associated with diarrhea the stool should have contained either gross or occult blood The x-ray studies also aid us in ruling out a neoplasm within the cecum I do not believe a cancer of the cecum could be so large as this mass apparently was without there being gross or microscopic blood in the stools, an anemia or conclusive x-ray evidence of the lesion It seems to me we must make a diagnosis other than that of neoplasm

If it is not that, and of course at the age of seventy-eight a neoplasm is the thing one thinks of first, what can it be? Has the gallstone anything to do with it? I doubt it very much, unless the gall bladder with its contained stone is fixed in the right lower quadrant and produces the palpable mass I once explored a mass in the right lower quadrant which I decided must be an appendiceal abscess because there was epigastric pain shifting to the right lower quadrant, but I found a gangrenous gall bladder containing a stone However, this mass in the right lower quadrant is rather large for that of a gall bladder

Is it possible we have some other rare condition? We must remember that, at the age of seventy-eight, appendicitis is always apt to be atypical It is in children and old people that the diagnosis of acute appendicitis is most often missed The symptoms and signs are so atypical that rupture may occur while the patient is being watched There is not the commensurate tenderness or spasm one is accustomed to find I believe it is possible that this man might have had an appendiceal abscess The fact the mass was movable does not rule out this diagnosis

What else could it be? One thinks of the various weird things he has seen and wonders if this is another Of course, there is the gangrenous appendix epiploica, and also diverticulum of the cecum with abscess formation Even foreign body in the omentum must be considered I remember taking out a mass only a couple of years ago which turned out to be a toothpick which the

patient had swallowed several months previously. It came out of the wall of the cecum, and I took it out of a large mass in the omentum. That, however, is not likely here.

Could it be intussusception? He had had barium by mouth as well as by rectum, and I believe there would have been evidence of this lesion in the x-ray. Regional ileitis is uncommon at this age. How about a retroperitoneal lipoma? They occur not infrequently, arising in the mesentery or retroperitoneal fat tissue, generally in the former, and may grow to a large size. It should not be as freely movable as this is said to have been because it is usually somewhat fixed to the posterior abdominal wall. Could it be urticaria of the cecum, with marked thickening of the bowel wall? It has been described, though I have never seen it. Is there anything to suggest sepsis? I have already said that at his age he would have had atypical symptoms, so that the temperature of only 99.5°F and the lack of leukocytosis do not eliminate infection. Tuberculosis I have not mentioned. Of course it occurs as a mass, but generally not at the age of seventy-eight and not coming on as acutely as this did. The same is true of mesenteric adenitis.

It seems to me the facts that he had had epigastric pain, that these symptoms came on in attacks, that he was apparently free of trouble until a very short time before admission, that he had no anemia and that the x-ray films suggest something outside the bowel all point to either an appendiceal abscess or some rare disease, such as retroperitoneal lymphosarcoma, which occasionally produces a picture such as this. I do not believe the mass could be connected with the urinary tract.

I am going to say appendiceal abscess first, and some unusual type of tumor second. When I operated I should have been ready to shift either way, depending on what was uncovered in the right lower quadrant of the abdomen.

DR CHANNING FROTHINGHAM: Would you not expect an appendiceal abscess of that size to be fairly well fixed?

DR YOUNG: Yes, but I have seen one that was very movable.

DR SIDNEY L. MORRISON: On looking at these x-ray films, I believe the mass is situated posteriorly and medially in the wall of the cecum. The surface seems too smooth for a carcinoma.

DR YOUNG: I have seen a freely movable mass that was due to chronic intussusception, but I should have suspected that the barium by mouth

would have shown evidence of such a lesion. Is that a fair assumption?

DR MORRISON: I should say so.

DR YOUNG: Another thing that would help rule out intussusception is the absence of occult blood in the stool.

A PHYSICIAN: Would you consider thrombosis of the mesenteric vessels?

DR YOUNG: I do not believe that there would be such a large mass, nor would the patient go nine weeks without presenting a more serious situation, even with intermittent thrombosis.

A PHYSICIAN: Is not an omental cyst to be considered?

DR YOUNG: It is too low for an omental cyst, considering the size of the mass. That is one reason why I rule out torsion of the omentum. I have never seen a cyst of the mesentery of the bowel in that location.

DR MORRISON: If it is in the wall of the cecum, it could not be an omental cyst.

#### CLINICAL DIAGNOSES

Lymphoblastoma?

Carcinoma of cecum?

Old appendiceal abscess?

#### DR EDWARD L. YOUNG'S DIAGNOSES

Appendiceal abscess?

Retroperitoneal lymphosarcoma?

#### PATHOLOGICAL DIAGNOSIS

Hodgkin's disease of the cecum, sarcoma type

#### PATHOLOGICAL DISCUSSION

DR J. BEACH HAZARD: At operation a segment of intestine was removed which included 15 cm of terminal ileum and 30 cm of the cecum and colon. The tumor was located in the cecum, encircling the ileocecal valve and replacing the cecal wall posteriorly and medially over an area approximately 10 by 8 cm. On section the tissue was of white "fish-flesh" appearance and formed a mass up to 7 cm in thickness. On the mucosal aspect it was evident as large, rounded, relatively smooth-surfaced projections. Histologically it was of cellular structure with a predominance of medium-sized round cells and with occasional cells of the Sternberg type. The regional lymph nodes were partly replaced by tumor. The diagnosis of Hodgkin's sarcoma was made.

The patient died one year after operation, but no autopsy was obtained.

## REPORT ON MEDICAL PROGRESS

### PSYCHIATRY

A WARREN STEARNS, MD \*

BOSTON

IN a general way, progress in the field of psychiatry during the year 1938 consisted in further development of work which had already begun in previous years. By far the most important development is the so-called shock treatment for dementia praecox and other psychoses. Readers have frequently been informed of the tremendous damage done by mental disease—one bed for mental disease for each bed for all other diseases in America. Of those cases accumulating in state hospitals roughly 75 per cent have been diagnosed dementia praecox, latterly called for reasons not too obvious, schizophrenia.

Until recently these cases presented a very hopeless picture. Occupational therapy, physiotherapy and other empirical procedures were largely palliative, and no specific attack was made on the diseased process itself. Organicists and psychogenesists vied with each other in elaborating the minutiae brought forth by their endeavors, but no one really claimed to understand the cause, nature or cure of this dread malady.

Then came the insulin-shock treatment, empirical to be sure, but opening up leads and hopes heretofore unknown. Following this, came the use of various other convulsants, especially Metrazol. All of this has had a tremendously invigorating effect on the whole field of psychiatry. Whereas one often sent patients to state hospitals solely for care, it has now become possible to think in terms of treatment. During the past year there have been a number of excellent publications, some of them dealing with large numbers of carefully treated cases. Compared with the roughly 20 per cent of remissions in untreated cases of dementia praecox, with insulin the incidence of such remissions of cases of less than one year's duration has varied from 50 to 85 per cent.<sup>1</sup> Conservative psychiatrists have hesitated to speak of cures, but there is a note of optimism in most of these reports. Similar results have been obtained with the use of Metrazol. Each has its advocates and it is not yet possible to decide between rival claims.<sup>2, 3</sup>

This work is not only of importance in the very practical matter of relief of patients, but its implications concerning the nature of mental disease are of fundamental importance. It has enlivened

state-hospital medicine in a very hopeful way. Incidentally, recent reports of the use of Metrazol in involutional depressions appear even more promising, some persons reporting 100 per cent of cures, after a relatively short period of treatment. As the year closes, this work is being extended in scope and area.<sup>4</sup>

Of less practical importance, but theoretically illuminating, is the work which has been done in the study of "brain waves." The passage of electrical currents through the brain results in certain conventional findings. These vary under certain conditions and especially in various mental diseases. The work promises to increase our understanding of impaired mental function, and certain investigators appear to be able to localize organic lesions by this method. It would seem at this time safe to assume that it will be an important aid in localizing brain tumors.<sup>5, 6</sup>

There has been further work in the application of experimental pharmacology to the field of psychiatry. Contemporary with certain physiological and chemical concepts concerning the autonomic nervous system, studies have been made of the effect of certain drugs in stimulating and inhibiting the complicated apparatus having to do with the emotional life of individuals, both sick and well.<sup>7, 8</sup> The drug, amphetamine (Benzedrine) sulfate, has been found useful in treating certain psychic states. While psychological studies have continued, the above appears to indicate a trend in the development of psychiatry toward the chemical and physiological rather than the psychological. It seems to bring the field of psychiatry a little closer to that of general medicine.

There has been a continued effort to stimulate the teaching of psychiatry in medical schools. Many data have been collected and published tending to show the relative importance of mental states in the field of medicine and their neglect by medical educators. As a result of these efforts there are many evidences of more time's being given in medical schools to psychiatry and related subjects.<sup>9, 10</sup>

Sociological disciplines have been invoked to an increasing extent as an aid to the understanding of certain psychiatric problems. The field of child guidance has been especially illuminated. A few years ago when dealing with problem children a good deal of attention was given to psychological

patient had swallowed several months previously. It came out of the wall of the cecum, and I took it out of a large mass in the omentum. That, however, is not likely here.

Could it be intussusception? He had had barium by mouth as well as by rectum, and I believe there would have been evidence of this lesion in the x-ray. Regional ileitis is uncommon at this age. How about a retroperitoneal lipoma? They occur not infrequently, arising in the mesentery or retroperitoneal fat tissue, generally in the former, and may grow to a large size. It should not be as freely movable as this is said to have been because it is usually somewhat fixed to the posterior abdominal wall. Could it be urticaria of the cecum, with marked thickening of the bowel wall? It has been described, though I have never seen it. Is there anything to suggest sepsis? I have already said that at his age he would have had atypical symptoms, so that the temperature of only 99.5°F and the lack of leukocytosis do not eliminate infection. Tuberculosis I have not mentioned. Of course it occurs as a mass, but generally not at the age of seventy-eight and not coming on as acutely as this did. The same is true of mesenteric adenitis.

It seems to me the facts that he had had epigastric pain, that these symptoms came on in attacks, that he was apparently free of trouble until a very short time before admission, that he had no anemia and that the x-ray films suggest something outside the bowel all point to either an appendiceal abscess or some rare disease, such as retroperitoneal lymphosarcoma, which occasionally produces a picture such as this. I do not believe the mass could be connected with the urinary tract.

I am going to say appendiceal abscess first, and some unusual type of tumor second. When I operated I should have been ready to shift either way, depending on what was uncovered in the right lower quadrant of the abdomen.

DR CHANNING FROTHINGHAM: Would you not expect an appendiceal abscess of that size to be fairly well fixed?

DR YOUNG: Yes, but I have seen one that was very movable.

DR SIDNEY L. MORRISON: On looking at these x-ray films, I believe the mass is situated posteriorly and medially in the wall of the cecum. The surface seems too smooth for a carcinoma.

DR YOUNG: I have seen a freely movable mass that was due to chronic intussusception, but I should have suspected that the barium by mouth

would have shown evidence of such a lesion. Is that a fair assumption?

DR MORRISON: I should say so.

DR YOUNG: Another thing that would help rule out intussusception is the absence of occult blood in the stool.

A PHYSICIAN: Would you consider thrombosis of the mesenteric vessels?

DR YOUNG: I do not believe that there would be such a large mass, nor would the patient go nine weeks without presenting a more serious situation, even with intermittent thrombosis.

A PHYSICIAN: Is not an omental cyst to be considered?

DR YOUNG: It is too low for an omental cyst, considering the size of the mass. That is one reason why I rule out torsion of the omentum. I have never seen a cyst of the mesentery of the bowel in that location.

DR MORRISON: If it is in the wall of the cecum, it could not be an omental cyst.

#### CLINICAL DIAGNOSES

Lymphoblastoma?

Carcinoma of cecum?

Old appendiceal abscess?

#### DR EDWARD L. YOUNG'S DIAGNOSES

Appendiceal abscess?

Retroperitoneal lymphosarcoma?

#### PATHOLOGICAL DIAGNOSIS

Hodgkin's disease of the cecum, sarcoma type

#### PATHOLOGICAL DISCUSSION

DR J. BEACH HAZARD: At operation a segment of intestine was removed which included 15 cm of terminal ileum and 30 cm of the cecum and colon. The tumor was located in the cecum, encircling the ileocecal valve and replacing the cecal wall posteriorly and medially over an area approximately 10 by 8 cm. On section the tissue was of white "fish-flesh" appearance and formed a mass up to 7 cm in thickness. On the mucosal aspect it was evident as large, rounded, relatively smooth-surfaced projections. Histologically it was of cellular structure with a predominance of medium-sized round cells and with occasional cells of the Sternberg type. The regional lymph nodes were partly replaced by tumor. The diagnosis of Hodgkin's sarcoma was made.

The patient died one year after operation, but no autopsy was obtained.

### CASE 25171

#### PRESENTATION OF CASE

A forty-three-year-old, white, married bank officer was admitted complaining of frequency of six months' duration.

For several years he had had to micturate about every two hours during the day. He had been impotent for nine months. His frequency had gradually increased during the previous six months, occurring some days as often as every twenty minutes. There was no difficulty in starting the flow, but the stream lacked force and he was unable to empty the bladder. After completion of urination dribbling occurred for several minutes. He had nocturia once each night. Occasionally there was uncomfortable burning on micturition, but there had been no hematuria or pyuria. There was no history of venereal disease. He had an aching sensation in the sacroiliac region, not aggravated by motion and never radiating, it was the same night and day, causing no incapacity, only discomfort. A year before admission he began having attacks of non-radiating pain about 2.5 cm to the right of the umbilicus. The pain persisted several hours, without anorexia, nausea or change in bowel habits. He had had several such episodes, two occurring during the week prior to entry. The pain was not affected by motion, food or alkalis. He had occasional episodes of gross bleeding by rectum, not always associated with tenesmus, although he knew that he had had hemorrhoids for several years. On several mornings he noted blood stains on his undergarments, presumably coming from the anus. He had had no tarry or mucoid stools and no change in bowel habits. His past and family histories were non-contributory.

Physical examination showed a well-developed, thin man in no distress. The fundi showed blurring of the disk margins. The teeth showed marked caries. The right posterior cervical lymph nodes were slightly enlarged, firm and matted. Examination of the chest was negative. The blood pressure was 115 systolic, 80 diastolic. The right kidney was palpable and tender. On deep palpation a firm, tender mass was encountered in both lower quadrants near the midline, apparently arising out of the pelvis. During urination the stream was weak but could be stopped on command. It

stopped three times, however, of its own accord during the one act of micturition observed. Rectal examination revealed a large pelvic tumor, firm but not hard enough to be bony. It seemed to originate on the left pelvic brim and extended across the posterior wall of the bladder. A proctoscope passed well above the tumor, examination showed a normal mucosa, but a collapsed lumen due to extrinsic pressure. A stool examination was negative. Cystoscopic examination was negative.

The temperature was 98.6°F, the pulse 90, and the respirations 18.

The urine examination showed only an occasional white cell and a small number of bacteria. A urine culture gave no growth. The red-cell count of the blood was 3,870,000 with 75 per cent hemoglobin, and the white-cell count 17,600. A lumbar puncture showed normal dynamics. There were no cells in the spinal fluid, but the protein was 45 mg per 100 cc. A spinal-fluid Wassermann test was negative. Two Frei tests were negative.

X-ray films showed transverse rather cylindrical areas of calcification at the superior margin of the urinary bladder, in the region of the seminal vesicles. Above these areas there was a round, smooth mass about 6 cm in diameter. There was no abnormality of the sacrum or lumbar spine. A barium enema showed the rectum displaced to the right and forward by the soft-tissue mass. The pressure defect in the rectum was smooth, with no evidence of involvement of the bowel.

On the ninth hospital day an operation was performed.

#### DIFFERENTIAL DIAGNOSIS

DR REGINALD H. SMITHWICK: A great deal of this history has to do with urinary tract symptoms. So far as I can see, the symptoms referable to the gastrointestinal tract are probably not of diagnostic significance. It is quite possible that the urinary symptoms have nothing to do with the diagnosis, but it might be interesting to try to follow them through to see if it is possible to come to a conclusion as to the nature and location of this tumor from that point of view. Before proceeding too far in that direction it might be well to see what the x-ray films show. Perhaps they are perfectly characteristic of the type of tumor this patient had.

DR AUBREY O. HAMPTON: They are not characteristic of anything I know about. I cannot add to the record, but I can point out the lesion. The mass is not so obvious on the film as you would expect it to be from the physical examination. I cannot see how it could arise from the brim of the pelvis, but since I cannot visualize the mass plainly, I must not argue too much about that.

mechanisms and much insight was gained as to child life. To this has recently been added the vast amount of material obtained by sociological investigations. It has been demonstrated that children growing up in certain neighborhoods or in certain types of homes are subjected to stresses not experienced by those in more favorable circumstances. The statistical method has been widely used, many new things have been learned, and many old errors have been corrected.<sup>11 12</sup> From many medical clinics have come studies indicating the relation between adverse social situations and the development of the neuroses.<sup>13</sup> Comparative studies of medical and social histories seem to show causal relation between situations and morbid emotional responses.<sup>14 15</sup> In one study, schizophrenia has been shown to be common in areas where other evidences of social maladjustment were most frequent, and the possibility of this disease's being precipitated or even caused by adverse social conditions is postulated.<sup>16 17</sup>

There have been two attitudes toward psychiatry in the past, one group has regarded it as a branch of medicine and has considered it solely from this light, while other groups have considered it as a way of life and have sought to leaven whole fields of human activity with certain points of view. The latter workers have continued to make progress in the fields of religion, education and law. Though some resistance has been made, in general it can be said that psychiatry has been well received by leaders in these various departments of human endeavor. We find an extension in the application of psychiatric principles to the field of

criminology.<sup>18</sup> Certainly the schoolteacher's attitude toward his work and especially his insight as to the mental life of his wards have been favorably influenced by psychiatry.<sup>19</sup> And finally, religious workers in dealing with the emotional life of individuals and their problems have learned much from the efforts of psychiatrists and psychologists.

Above these areas there was a round, smooth mass about 6 cm in diameter. There was no abnormality of the sacrum or lumbar spine. A barium enema showed the rectum displaced to the right and forward by the soft-tissue mass. The pressure defect in the rectum was smooth, with no evidence of involvement of the bowel.

On the ninth hospital day an operation was performed.

## DIFFERENTIAL DIAGNOSIS

DR. REGINALD H. SMITHWICK. A great deal of this history has to do with urinary tract symptoms. So far as I can see, the symptoms referable to the gastrointestinal tract are probably not of diagnostic significance. It is quite possible that the urinary symptoms have nothing to do with the diagnosis, but it might be interesting to try to follow them through to see if it is possible to come to a conclusion as to the nature and location of this tumor from that point of view. Before proceeding too far in that direction it might be well to see what the x-ray films show. Perhaps they are perfectly characteristic of the type of tumor this patient had.

DR. AUBREY O. HAMPTON. They are not characteristic of anything I know about. I cannot add to the record, but I can point out the lesion. The mass is not so obvious on the film as you would expect it to be from the physical examination. I cannot see how it could arise from the brim of the pelvis, but since I cannot visualize the mass plainly, I must not argue too much about that.

point To me it looks as though it were free of the pelvic brim and in the middle, but at the time of the barium-enema examination, the defect is larger than the visible soft-tissue shadow so we must see only part of it This calcification interests me more than does anything else I do not remember ever having seen a blood vessel in such a horizontal position in the pelvis, and yet it looks like a blood vessel that is completely calcified I have tried to place it in the seminal vesicles, but it is not the shape of a seminal vesicle From what we can see of the mass I should say it was more kidney-shaped than round

DR SMITHWICK Do you think it is in the midline?

DR HAMPTON It does not deform the bladder so much as it does the rectum

DR SMITHWICK Apparently this is not a very large tumor

DR HAMPTON It is situated in the hollow of the sacrum We might say that it is more or less in the midline There is a peculiar area of calcification near it

DR SMITHWICK Unless this patient has some totally dissociated lesion, presumably of the central nervous system, to give him all his urinary symptoms, it is difficult to explain them on the basis of a tumor of this size, although the location of the tumor is such that it conceivably might interfere with the nerve supply to the bladder We see many tumors in the pelvis, of course, of various sizes, and they rarely cause any such urinary symptoms as these unless they are so large that they produce some mechanical difficulty in emptying the bladder Nothing is said about reflex or sensory disturbances of the extremities, and his lumbar-puncture findings I should say are within normal limits So I think it is fair to rule out a central-nervous-system lesion which might contribute to this picture

How significant this question of impotence is, I have no idea We know that the genitourinary organs have a very complicated nerve supply, coming from three sources—sympathetic, parasympathetic and somatic We know that the parasympathetic nerves have to do with the initiation of intercourse, and that the sympathetic ones have to do with the termination of intercourse We also know that the sympathetic nerves are concerned in the filling of the bladder, and the parasympathetic ones in the emptying of the bladder He seems to have had trouble with the emptying of his bladder, and yet there is no intrinsic tumor of the genitourinary tract to explain the situation As the parasympathetic nerve supply to the bladder comes from just about where this tumor lies in the region of third and fourth sacral segments, it is conceivable that by pressure on the proper

segments a tumor of this size might cause these symptoms However, a more likely possibility is that the tumor is of neurogenic origin, such as a neurofibroma or neuroblastoma, such a tumor might adequately explain this history

His abdominal pain does not seem to be characteristic of anything, perhaps it is some sort of referred pain We know he had hemorrhoids, and I suppose a tumor which displaces the rectum forward and anteriorly might increase venous stasis sufficiently to explain the bleeding, furthermore, the bleeding seems sufficient to explain the anemia There is no evidence of infection other than the elevated white count The findings certainly do not suggest an inflammatory process or abscess of pyogenic origin or a retroperitoneal tuberculous lesion The fact that the tumor is about in the midline raises the possibility of its being a midline mixed tumor with calcification or a dermoid cyst, but it seems to me that if the history is significant and one tries to explain this unusual urinary picture and relate it to a tumor of moderate size, which the patient obviously had, perhaps the best possibility is that this patient had a retroperitoneal tumor of neurogenic origin

DR AUGUSTUS ROSE I was asked to see this patient in order to determine if his difficulties were due to disease of the nervous system There was no evidence of any neurologic change except as noted in the record The impotence was very definite, and I believed that it was associated with his poorly functioning bladder I observed the emptying of his bladder, and it was definite that he had a weak stream but could stop and start it on command The frequency was present in the daytime and seemed to be due to a subjective feeling of a full bladder There was no urgency I reasoned, more or less as Dr Smithwick has done, that it was a disturbance in the peripheral nerve supply, probably parasympathetic

#### PREOPERATIVE DIAGNOSES

Dermoid cyst in pelvis?  
Lymphoma?

#### DR. SMITHWICK'S DIAGNOSIS

Retroperitoneal tumor of neurogenic origin

#### ANATOMICAL DIAGNOSIS

Ganglioneuroma of sacral plexus

#### PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY The preoperative diagnosis was a dermoid cyst I imagine they were influenced by the calcification seen in the x-ray films He was explored by Dr James E Fish, who found a large, very firm and dense tumor nearly filling the posterior and left half of the

pelvis It was very difficult to find any line of cleavage, but it was finally possible to dissect it anteriorly off the bladder and rectum but not posteriorly off the pelvic wall Ramifications of the tumor were seen to extend into the sacral foramina, and it was necessary to cut across these, thus leaving tumor behind Perhaps two thirds of the tumor was resected By that time it was quite evident that it was a neurogenic tumor The sections show a very characteristic ganglioneuroma made up of twisting bundles of nerve fibers and ganglion cells

## CASE 25172

### PRESENTATION OF CASE

A fifty-nine-year-old single nurse was admitted complaining of substernal distress of fourteen years' duration

At the age of forty-five years she contracted an undiagnosed illness characterized by fever and prostration, following this she began to notice substernal distress with exercise, at first with great exertion but later with relatively little effort During the previous few years she had had attacks which awakened her at night There were occasional attacks during the day while lying on a couch During an attack she had a sensation of tightness and squeezing beneath the sternum and according to an observer became pale and cold and had to stand to obtain relief The pain sometimes radiated around the left side of the chest to the back, but not down the arms At times there was a sensation of numbness in both arms Heat was used for relief, she had never taken nitroglycerin Between attacks there was slight palpitation and dyspnea on exertion, but there had been no edema or cough Three years before admission she was seen at another clinic where she was told that she had achlorhydria, an irritable colon and a "nervous" heart Several months of treatment with belladonna and hydrochloric acid gave no relief

Physical examination showed a well-developed, fairly well-nourished woman in no distress The fundi showed moderate arteriosclerosis and arteriovenous nicking The lungs were negative The heart did not seem to be enlarged At the cardiac apex there was a loud blowing systolic murmur, and over the sternum and aortic area a blowing systolic murmur  $A_2$  was accentuated The blood pressure was 150 systolic, 80 diastolic The remainder of the physical examination was negative

The temperature was  $98.6^{\circ}\text{F.}$ , the pulse 80, and the respirations 20

The urine examination was negative A phenolsulfonephthalein kidney-function test was normal The blood showed a red-cell count of 3,670,000

with 70 per cent hemoglobin, and a white-cell count of 7500 with 64 per cent polymorphonuclears The serum nonprotein nitrogen was 19 mg per 100 cc, the fasting cholesterol 149 mg A blood Hinton test was negative The basal metabolism rate was -15 per cent An electrocardiogram showed low  $T_1$  and  $T_2$ , inverted  $T_3$  and diphasic  $T_4$   $S-T_1$  and  $S-T_2$  were sagging,  $Q_3$  prominent X-ray films of the chest were negative

On the day of entry, while the history was being taken, the patient began to complain of tightness in the chest Within four minutes the blood pressure rose to 195 systolic, 136 diastolic Three minutes later 1/100 gr of nitroglycerin was given, this relieved the pain in about five minutes, but the blood pressure remained at 190 systolic, 120 diastolic, at the end of twelve minutes The pain returned (blood pressure 190 systolic, 126 diastolic), subsided in six minutes (blood pressure 180 systolic, 100 diastolic) and returned again in ten minutes (blood pressure 192 systolic, 128 diastolic) She stated that her systolic blood pressure at rest was 120, but that any excitement raised it

Two days later, while at rest, the blood pressure ranged between 140 systolic, 98 diastolic, and 170 systolic, 122 diastolic A blood pressure cuff was placed on the left arm and inflated Within five minutes the blood pressure had risen to 190 systolic, 130 diastolic, and the patient complained of pain in the left arm

On the sixth hospital day, while at rest, the blood pressure was 150 systolic, 120 diastolic The patient was given a cigarette to smoke and within three minutes the blood pressure was 185 systolic, 130 diastolic, and the patient complained of slight substernal pain The cigarette was taken away and one nitroglycerin tablet given The blood pressure, however, remained elevated and the pain continued, becoming progressively worse Two minutes after the first tablet another nitroglycerin tablet was given, but the pain continued Five minutes after the initiation of pain a third nitroglycerin tablet was given, and within one minute the pain decreased and within four minutes had disappeared Throughout this entire period the blood pressure ranged between 180 systolic, 140 diastolic, and 190 systolic, 130 diastolic At the time the pain disappeared the blood pressure was 180 systolic, 116 diastolic

On the nineteenth hospital day an electrocardiogram showed no changes since the previous record Nitroglycerin gave her much relief, but she continued having attacks, more at night than during the day On the afternoon of the sixtieth hospital day she developed a very severe substernal pain, which was not relieved by nitroglycerin and sodium luminal Her abdomen became somewhat distended She developed an ashen color The

pulse was good, and the blood pressure 160 systolic, 120 diastolic. There were no changes in the heart tones. One day later the white-blood cell count was 17,100. She felt much better and had obtained relief from nitroglycerin. An electrocardiogram showed normal rhythm, a rate of 80, T<sub>1</sub> diphasic and T<sub>4</sub> inverted. One day after this her blood pressure was 100 systolic, 85 diastolic. The heart sounds were of poor quality. There were a few crepitant rales at the lung bases. At 5 a. m. the next day, stertorous breathing suddenly began, and she was unable to respond, though entirely conscious. The right face, arm and leg showed flaccid paralysis. Examination of the heart showed no change. On the sixty-seventh hospital day a right hemiplegia was still present, and the patient lapsed into deep coma. She died two days later.

#### DIFFERENTIAL DIAGNOSIS

DR WILFRID COMEAU. The history as given here is almost a textbook picture of a woman who over a period of fourteen years has developed progressively increasing coronary insufficiency and finally angina pectoris decubitus. If we had more information it would be interesting to speculate as to whether the undiagnosed illness was a coronary thrombosis. It is just as likely, however, that this illness was not related to her heart but that it caused her to focus her attention on herself and she became aware of symptoms which she had not noted previously. I stated that the history was *almost* a textbook picture because there is one atypical feature, namely that the pain radiated to the back. It is very rare in angina pectoris due to coronary disease for pain to be referred to the back. In such cases one usually thinks of aortitis and, of course, in an acute episode, of a dissecting aneurysm. However, in spite of the slightly atypical nature of the pain, I do not see how one can escape from the conclusion that she was having progressive coronary insufficiency. In view of certain features of her illness which are mentioned later, there are certain points to be noted in her history: (1) during the attacks she became pale and felt cold, definite evidence of vasoconstriction, (2) there were no symptoms of hypertensive crises, and (3) no symptoms were present to suggest cardiac failure. I do not attach a great deal of significance to the palpitation and dyspnea.

I shall admit that I am a bit disturbed about the auscultatory findings. At best it is difficult, even when you are listening, to interpret murmurs such as are described here, particularly when the heart is normal in size. I should appreciate more detailed information in regard to the quality of the murmur. Instead of being two murmurs, was this one murmur which was widely transmitted

and loudest in one area? One would like to know whether a thrill was present, and in addition, since the individual was a nurse, it is quite possible that she might have known how long she had had this murmur. In any case, with the information presented here certain things definitely come to mind that might possibly explain the auscultatory findings. Aortic dilatation and tortuosity, of course, is one and is not uncommonly the cause of an aortic systolic murmur in old individuals. Ventricular dilatation can cause such murmurs as these, although again the lack of cardiac enlargement is against such an assumption. The foremost which comes to mind is aortic stenosis. That might explain the loud blowing systolic murmur heard all over the precordium and under the sternum. I do not believe I am carrying the differential diagnosis too far in suggesting a septal defect because, after all, people with septal defects do live to an old age, and on occasions such a diagnosis is missed because of the age of the patient. Then too, on rare occasions to be sure, people with coronary heart disease and coronary thrombosis do perforate their septums and survive. It might be well to look at the x-ray films and eliminate some of the possibilities which I have mentioned.

DR RICHARD SCHATZKI. The x-ray film is negative so far as the heart is concerned, it is of normal size and shape. The patient has evidence of a primary tuberculous process or Ghon's tubercle on the left side with corresponding hilar calcification and evidence of old scarring at the apices. The aorta is tortuous and elongated but not definitely dilated.

DR COMEAU. In view of the x-ray picture and the fact that the size of the heart is normal, I am satisfied to explain the murmurs on the basis of a tortuous aorta. The basal metabolic rate is at the lower limits of normal, but I do not attach much significance to this or to the other laboratory findings. The electrocardiograms show only slight changes, but nevertheless changes which are consistent with coronary heart disease. The charts show that excitement, the pain of the blood pressure cuff and tobacco caused a marked rise in both the diastolic and the systolic blood pressures, averaging about 25 mm. of mercury for the former, with a high point of 35 mm., and 40 mm. for the latter, with a high point of 50 mm. Of course the point to decide is whether these changes in blood pressure were due to organic disease. There is no indication in the history and physical examination to suggest prolonged arterial hypertension. One could suggest an adrenal chromaffin tumor, but the lack of hypertensive crises and the length and nature of her illness do not allow such a diagnosis to be entertained. The rise of

blood pressure which accompanied her angina is not unusual, and it probably occurs quite commonly. Similarly, a rise of blood pressure during coronary thrombosis, although it is classically described as falling, is not uncommon during the period of pain. When the pain is relieved or if shock develops, then the blood pressure falls. All these data on the blood pressure, I believe, merely indicate an abnormal response of the autonomic nervous system to excitement, pain and tobacco. It is true that these three factors in a normal individual may cause slight rises in diastolic and systolic pressures. In this case, if I am correct, it means she had a very unusual response to such stimuli. Certainly I have never seen a diastolic rise of 35 mm from such factors as we have mentioned. In chronic hypertension there are reports that emotion has occasionally caused an elevation of the diastolic blood pressure as high as 25 mm., but there is no evidence that this patient's blood pressure was elevated constantly to any marked extent.

It seems that the expected sequence of events occurred in this case, namely a very severe attack of substernal pain, which I interpret as an attack of coronary thrombosis. The changes in the electrocardiogram, even slight as they are, are strong confirmation that such has occurred. The fact that the blood pressure did not fall is probably due to the point which I brought up previously, since it fell later, after she had recovered from pain. Three days later she developed cerebral symptoms which I interpret as due to a cerebral embolus from a mural thrombus in the left ventricle, perhaps this is a little early for such to occur, but it is not incompatible. In summary then, my conclusion is that this individual had marked coronary heart disease with severe angina pectoris for a number of years. She had at least one coronary occlusion, which occurred a few days before her death, with the formation of a mural thrombus in the left ventricle, which, in turn, resulted in a cerebral embolus.

DR ASHTON GRAYBIEL: The only other point I might mention is that an electrocardiogram taken after slight exercise, such as walking down the hall, showed marked inversion of the T waves in Leads 1 and 2. This is the first time I have seen such marked changes in the T waves as a result of exercise.

A PHYSICIAN: Did anyone contemplate surgery for relieving this condition?

DR GRAYBIEL: Yes, surgical procedures were considered and that is the reason some of the tests were done. When she came in she had a moderately severe secondary anemia. Dr Howard B. Sprague saw her with me at that time and we thought that it would be advisable to observe first

the extent of improvement following remission of the anemia.

#### CLINICAL DIAGNOSES

Angina pectoris decubitus  
Coronary thrombosis  
Cerebral thrombosis

#### DR COMEAU'S DIAGNOSES

Coronary heart disease, with angina pectoris decubitus  
Coronary thrombosis, with mural thrombus  
Cerebral embolus

#### ANATOMICAL DIAGNOSES

Arteriosclerosis, coronary and aortic  
Coronary thrombosis, old and recent  
Myocardial infarction, recent  
Hydrothorax, bilateral  
Pulmonary atelectasis  
Healed pulmonary tuberculosis  
Chronic cholecystitis  
Cholelithiasis

#### PATHOLOGICAL DISCUSSION

DR TRACY B. MALLORY: The postmortem showed very severe coronary changes. The right coronary artery was completely blocked with an old calcified mass that had evidently been present for years. The left coronary and each of its two main branches were markedly narrowed by old sclerotic plaques, and there was a quite fresh thrombus in the left descending branch. Corresponding to that was a small area of fresh infarction at the apex, about 2.5 cm in diameter. We did not find evidence of any old infarction. There was no ventricular thrombosis overlying the infarct, and although we did not have permission to examine the head, I am tempted to believe the cerebral lesion was a local thrombosis rather than embolism, because shortly after the cardiac infarction occurred the blood pressure dropped and for a considerable period the pulse pressure was not over 20 mm., all of which would favor thrombosis.

DR PAUL D. WHITE: Was the aortic valve all right?

DR MALLORY: It was completely negative and offered no explanation for the murmurs. There was one other observation made, however, which I believe is significant. The aorta did not appear markedly sclerotic in the sense that there were not many atheromatous plaques, but when one attempted to stretch a segment of the aorta it proved to be almost completely inelastic.

DR WHITE: Was the left ventricle dilated?

DR MALLORY: No, and the heart as a whole was small.

DR COMEAU: How much did it weigh?

DR MALLORY: Two hundred and fifty grams.

pulse was good, and the blood pressure 160 systolic, 120 diastolic. There were no changes in the heart tones. One day later the white-blood cell count was 17,100. She felt much better and had obtained relief from nitroglycerin. An electrocardiogram showed normal rhythm, a rate of 80, T<sub>1</sub> diphasic and T<sub>4</sub> inverted. One day after this her blood pressure was 100 systolic, 85 diastolic. The heart sounds were of poor quality. There were a few crepitant rales at the lung bases. At 5 a. m. the next day, stertorous breathing suddenly began, and she was unable to respond, though entirely conscious. The right face, arm and leg showed flaccid paralysis. Examination of the heart showed no change. On the sixty-seventh hospital day a right hemiplegia was still present, and the patient lapsed into deep coma. She died two days later.

#### DIFFERENTIAL DIAGNOSIS

DR. WILFRID COMEAU The history as given here is almost a textbook picture of a woman who over a period of fourteen years has developed progressively increasing coronary insufficiency and finally angina pectoris decubitus. If we had more information it would be interesting to speculate as to whether the undiagnosed illness was a coronary thrombosis. It is just as likely, however, that this illness was not related to her heart but that it caused her to focus her attention on herself and she became aware of symptoms which she had not noted previously. I stated that the history was *almost* a textbook picture because there is one atypical feature, namely that the pain radiated to the back. It is very rare in angina pectoris due to coronary disease for pain to be referred to the back. In such cases one usually thinks of aortitis and, of course, in an acute episode, of a dissecting aneurysm. However, in spite of the slightly atypical nature of the pain, I do not see how one can escape from the conclusion that she was having progressive coronary insufficiency. In view of certain features of her illness which are mentioned later, there are certain points to be noted in her history: (1) during the attacks she became pale and felt cold, definite evidence of vasoconstriction, (2) there were no symptoms of hypertensive crises, and (3) no symptoms were present to suggest cardiac failure. I do not attach a great deal of significance to the palpitation and dyspnea.

I shall admit that I am a bit disturbed about the auscultatory findings. At best it is difficult, even when you are listening, to interpret murmurs such as are described here, particularly when the heart is normal in size. I should appreciate more detailed information in regard to the quality of the murmur. Instead of being two murmurs, was this one murmur which was widely transmitted

and loudest in one area? One would like to know whether a thrill was present, and in addition, since the individual was a nurse, it is quite possible that she might have known how long she had had this murmur. In any case, with the information presented here certain things definitely come to mind that might possibly explain the auscultatory findings. Aortic dilatation and tortuosity, of course, is one and is not uncommonly the cause of an aortic systolic murmur in old individuals. Ventricular dilatation can cause such murmurs as these, although again the lack of cardiac enlargement is against such an assumption. The foremost which comes to mind is aortic stenosis. That might explain the loud blowing systolic murmur heard all over the precordium and under the sternum. I do not believe I am carrying the differential diagnosis too far in suggesting a septal defect because, after all, people with septal defects do live to an old age, and on occasions such a diagnosis is missed because of the age of the patient. Then too, on rare occasions to be sure, people with coronary heart disease and coronary thrombosis do perforate their septums and survive. It might be well to look at the x-ray films and eliminate some of the possibilities which I have mentioned.

DR. RICHARD SCHATZKI The x-ray film is negative so far as the heart is concerned, it is of normal size and shape. The patient has evidence of a primary tuberculous process or Ghon's tubercle on the left side with corresponding hilar calcification and evidence of old scarring at the apices. The aorta is tortuous and elongated but not definitely dilated.

DR. COMEAU In view of the x-ray picture and the fact that the size of the heart is normal, I am satisfied to explain the murmurs on the basis of a tortuous aorta. The basal metabolic rate is at the lower limits of normal, but I do not attach much significance to this or to the other laboratory findings. ## PNEUMONIA PROPHYLAXIS

FROM the point of view of both mortality and disability, pneumonia is now recognized as the most important acute infectious disease. It is for that reason that, following the pandemic of influenza in 1918, the Metropolitan Life Insurance Company became interested in furthering research in the control of this disease. Ostensibly set up for the purpose of promoting studies of influenza, the Influenza Commission of the Metropolitan Life Insurance Company, headed by Dr. Milton J. Rosenau, soon saw the wisdom of extending its support to pneumonia investigation. The most important studies carried out under grants from this commission were those conducted at the Harvard Medical School by Dr. Lloyd D. Felton, who succeeded in making the specific serum ther-

apy of pneumonia feasible, safe and effective. The results of his laborious studies in this field have been applied with various modifications to the concentration and purification of antipneumococcus horse and rabbit serums of various types and these, in turn, have become effective weapons in controlling the death rate from the pneumococcal pneumonias.

In addition to the great importance of this disease in the general population, it is now becoming increasingly apparent that, under the proper conditions, the pneumococcal pneumonias may take on epidemic proportions. This epidemic character was first recognized in the United States Army camps during the World War. Greater impetus has been given to the epidemiological studies on pneumonia by the widespread use of pneumococcus typing facilities, particularly following the classification of the pneumococci which did away with the former miscellaneous Group 4 and substituted in its place specific Types 4 to 32. Epidemics have been recognized in families, in children's homes, in hotels for transients, in state institutions for mental disease, in institutions for disabled veterans, in CCC camps, and in small communities. The very great prevalence of pneumonia in certain localities, notably Pittsburgh and the mining regions of British South Africa, is almost in the nature of recurrent epidemics.

The use of vaccines for the prevention of pneumonia had its first extensive trials under Lord Lister in the South African mining camps and also had some trials in our army camps during the World War. Whole bacterial vaccines were used. The immunological evidence at that time and, indeed, since then, has indicated the strictly type-specific character of the antibody response to such vaccines. The extensive studies of Lister, with the more recent collaboration of Ordman, have indicated that if the types of pneumococci prevalent in the pneumonia of a given locality are included in a vaccine, the persons inoculated with such vaccines are protected against pneumonia due to these types. But other types of pneumococci soon appear and pneumonia recurs.

Felton's more recent studies have been con-

cerned with the difficult problem of isolating immunizing antigens which are free from untoward reactions and have a wide antigenic activity. These studies, begun at the Harvard Medical School and continued at Johns Hopkins University School of Medicine and now at the National Institute of Health, are gradually bearing fruit. In his most recent report Felton<sup>1</sup> summarizes the chemical and immunological characteristics of fractions of pneumococci which are antigenic for both mice and human beings. He also presents a method of testing for the presence of substances responsible for untoward reactions when injected into human beings, as well as methods of treating the antigens so as to eliminate these untoward reactions.

Felton has succeeded in preparing a Type 1 antigen which was type-specific in white mice but which, when injected in children, produced antibodies against Type 2 in as high a titer as against Type 1. Conversely a specific Type 2 antigen stimulated Type 1 antibodies only rarely in children. In adults, however, both these antigens stimulated heterologous immunity.

An antigen prepared by Felton's method has been used recently in Massachusetts to control an institutional outbreak of Type 1 pneumonia, with apparent success.<sup>2</sup> A much wider study of the prophylactic value of this antigen has been undertaken in the CCC camps under Col. Ekwurzel and Lt. Col. Simmons of the Medical Corps of the United States Army. A careful statistical analysis<sup>3</sup> of their results has been recently presented. To quote

In the New England camps the pneumonia incidence rate was 4.34 cases per 1000 years of life in the inoculated group as compared with 7.28 per 1000 years of life in the control group. The corresponding figures for the West Coast camps are 1.73 and 15.69 per 1000 years of life, respectively. Thus the findings of the 1936-37 experiments are consistent with the impressions gained from the other preliminary experiments. Taking all the experiments together, it appears that this or a similar antigen may prove to be a useful tool for the control of pneumonia incidence.

There is some indication that the antigen may be most effective for adolescents and that it loses its effectiveness with advancing age. It was found in the New England camps that, at ages under twenty, the pneumonia incidence rate in the control group was

27 times that in the inoculated group, at ages twenty to twenty four, the ratio was 1.4, and at ages twenty five to forty nine, the inoculated enrollees actually experienced a higher rate than the control group.

There was no satisfactory evidence found to show that the antigen will lower the incidence of respiratory conditions other than pneumonia. Enrollees in the inoculated group in the New England Civilian Conservation Corps camps lost from duty an average of 4.22 days per 1000 days exposed to risk of infection, while the corresponding figure for the group not inoculated was 4.38 days per 1000 exposed.

These results are encouraging, and the studies are being continued in the CCC camps and in the regular army.

#### MATRIMONIAL MONTHS OF THE NATIONS

THE Metropolitan Life Insurance Company, for reasons not divulged but possibly actuarial, possibly to lend color to one of its recent statistical bulletins, has studied the marriage months of choice of various countries situated in various climes.

Apparently the proverbial June bride is not proverbial everywhere. Even in the United States the month of June with 13 per cent of the marriages leads September, the second choice, by only 2 per cent. Canada closely approximates our figures. Down under, in Australia and New Zealand, the British territories of the southern hemisphere, the corresponding month of December leads with brides and roses, with the fall month of April a close second choice.

In other countries the seasons when holy wedlock occupies the minds of proletariat and gentry alike are determined by a variety of conditions, among them climate, religion, superstition, racial customs, degree of urbanization, economic status and occupation. Peoples that are primarily agricultural apparently prefer the fall when harvests have been gathered, profits, if any, pocketed and leisure

Thursday, May 4, at 4 30 p m, in John Ware Hall, Boston Medical Library, 8 Fenway, Boston Subject—Medical Complications in Pregnancy Instructor M V Kappius. Reginald Fitz, *Chairman*

#### THE CHILD AND HIS ENVIRONMENT\*

Some of you—perhaps many of you—have read A. A. Milne's whimsical little book, *Winnie-the Pooh* and will smile at the recollection of the old grey donkey, Eeyore. Eeyore always had a chip on his shoulder. He was always being slighted, at least in his own mind, and he was always grumbling, despite the fact that the other creatures of the wood really went out of their way to be kind to him. Eeyore's reply to a morning greeting is typical.

Good morning, said Eeyore. 'If it is a good morning, he said 'Which I doubt,' said he 'Not that it matters, he said'

Eeyore, melancholy old donkey that he was, was sadly out of tune with his environment. He was maladjusted, to use a modern but expressive term. Something must have happened to him in some forgotten corner of his childhood that prevented him from getting along with people as he grew older. Some disappointment had come to him, or some fear had been planted in his mind, or some injustice had built up in him a resentment toward his fellow beings. Perhaps he was shy and sensitive and protected himself from further wounding by a gruff exterior. Perhaps he was a round peg in a square hole, or a square peg trying to accommodate itself to a round hole. Whatever the reason, his personality did not click and he did not have fun like other donkeys, and the pigs and tigers and kangaroos and teddy bears in the book that might have been his friends

The environment, according to Webster's dictionary, consists of the surrounding conditions, influences or forces that bear on us. When applied to the individual child, this means the small world in which he lives and moves,

and the people in it with whom he must come in contact—in the home and in the school, at work and at play. A happy adjustment exists when the environment, by its nature or by the changes that we are able to make in it, suits the individual, and when the individual, by nature or by the changes that can be made in him, suits his environment.

We must assume, at the start, that all holes are not round, convenient as it would be to have them so, and that pegs come in many odd and uncomfortable shapes. Sometimes we can shape the hole of environment a little or a good deal, depending on circumstances, more often our task is to try and shape the child peg to fit as comfortably as possible into the world that the centuries formed for him.

During the months of the child's infancy, our opportunity to improve his environment is the greatest. We can furnish suitable food for him, we can give him a place to rest and the opportunity to use it, we can modify his formula to meet his needs, we can give him sunlight, cod liver oil and orange juice, we can see that he is not too cold and not too warm, we can keep uncomfortable friends and relatives from him. We can see to it that he has the advantages of comfortable clothes and bedding, and proper soaps and powders and washcloths and towels. In these ways we can alter and improve both his physical and his mental environments.

As he grows older, as he grows farther away from the close, protective environment that we had hitherto been able to furnish for him, our task becomes harder. He is outgrowing us, and one of our greatest mistakes lies frequently in trying to prevent this outgrowing process. When our child was a baby, each detail of his life needed superintendence for his own good. As he matures, we must take care that we do not tie him to our apron strings, that we do not try to keep him in the hothouse environment that his infancy seemed to require.

Less and less, now, can we adapt the environment to the child. We can still see that he has proper clothing and suitable shoes, that his room is occasionally aired and properly warmed, that he has a comfortable bed and a reasonable diet and the correct vitamins, both in number and amount. We can try and furnish him with the right type of play materials, and proper companions, and eventually, so far as it is in our power to select it, the right school. In these ways we can still fit the environment to the child. Most of all, by our own attitudes and our own composure and self-control, we can furnish a pattern of behavior that may eventually be adopted, for the child is by instinct imitative. Let us give him something worthwhile to imitate, then, not a pattern of behavior of which we are ourselves ashamed, when we stop to think it over.

In these ways we can continue to adapt the environment to the child. We must, however, in increasing measure, recognize the truth that our children will be forced to meet and live in a world that has already hardened into its age-old lines of conduct. It is a world of competition, of selfishness and of greed, yet with its occasional kindly aspects cropping up here and there. This we cannot change, and our duty from the beginning is so to prepare the children of the world that they can adapt themselves to its many-sided influences. This is the permanent environment to which they must adjust their lives in order to live happily and competently.

Adapting the child to the environment is a process that begins with his birth. It might almost be said to begin before his birth, since the care that is given to the mother has its effect also on the physical well-being of

\* Green Lights to Health broadcast given by Dr. Joseph Garland on Wednesday, February 8, and sponsored by the Public Education Committee of the Massachusetts Medical Society and the Massachusetts Department of Public Health.

is presumably ahead, for the giving and taking in marriage

Piscatorial countries such as Norway and Scotland turn marriage-minded in December after the return of the fishing fleets from their cruises of the previous spring and summer. Religion and creed are important factors in determining the seasonal incidence of weddings, for in periods of religious fasting and penitence few marriages are solemnized. Periods of religious festivity, on the other hand, are particularly suitable for wedding seasons. Thus, during the Lenten season in Catholic countries, and during the Passover period among the Jews, few marriages are celebrated. In Greek Orthodox countries, such as Bulgaria and Roumania, February, the month before Lent, is the popular marriage month, in Roman Catholic countries the preference is to postpone the wedding ceremony until after the Lenten season. Among both Roman and Greek Catholics the Christmas holiday season is considered a propitious time for joining in wedlock. Among the Swiss and the Germans, May, the spring festival month, is favored for embarking upon the sea of matrimony.

The world over, north and south and east and west, March seems to be the least popular month for marriage, closely followed in its unpopularity by January and August. Apparently the extremes in temperature are not propitious.

### POSTPARTUM HEMORRHAGE REVIEW

The first case of postpartum hemorrhage was presented in the January 26 issue of the *Journal*. From then through April 20, cases illustrative of this condition have been reported, 13 in all. In subsequent numbers, bleeding during the puer-

perium will be taken up, but before publishing these cases it seems worthwhile to review the cases of postpartum hemorrhage.

We have found no cases of postpartum hemorrhage associated with hydramnios or with twins *per se*. There have been no cases reported in which hemorrhage was of sufficient importance to be classified as a complication in connection with vestibular or perineal lacerations. This does not mean that postpartum hemorrhage is never associated with these conditions, but it does suggest that these conditions are negligible as common etiologic factors.

Of the total number of cases reported there was only 1 in which an adherent, partially separated placenta played a large part in the accompanying hemorrhage. Nevertheless we believe that such placentas must still be classified as among the frequent etiologic factors.

Deep cervical lacerations have been shown to be common causes of postpartum hemorrhage, and it must be borne in mind that such lacerations may rarely occur in normal labors. The frequency of postpartum hemorrhage associated with torn cervixes as a result of accouchement *forcé* has been brought out. We hope that the operation has been so condemned that, in the future, postpartum hemorrhage from this source alone will occupy the negligible place that it deserves, the operation, itself the cause of the condition, is never indicated.

The purely atonic uterus, which may follow any labor, is still the commonest cause of postpartum hemorrhage. The cases reported illustrate the possibility of this condition associated with labors that are abnormal in no degree.

How best should they be treated? To be prepared adequately to meet this emergency, all patients should be hospitalized. In no other way can severe postpartum hemorrhage be treated perfectly. There is still some difference of opinion as to the need of carefully watching the fundus after the birth of the baby, it seems, however, that in no other way can one be sure that the uterus is not relaxing and filling with blood.

The routine use of some form of posterior pituitary extract as soon as the baby is born may initiate normal uterine rhythm. The intelligent expression of the placenta when it has separated, but not until it has separated, will oftentimes prevent the accumulation of blood in the uterus after placental separation. The routine intramuscular use of ergot after the birth of the baby will further stimulate normal uterine contractions. Complete preparation for transfusion, so that lost blood may be replaced without delay in order to make up lost fluid and to combat shock, is undoubtedly

\*A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

the most important single piece of routine in combating hemorrhage from an atonic uterus

Conservatism in operating, preparation so that transfusion may be accomplished without delay and universal hospitalization represent the ultimate in combating the fatalities due to postpartum hemorrhage

#### THE CHILD AND HIS ENVIRONMENT\*

Some of you—perhaps many of you—have read A. A. Milne's whimsical little book, *Winnie-the-Pooh* and will smile at the recollection of the old grey donkey, Eeyore. Eeyore always had a chip on his shoulder. He was always being slighted, at least in his own mind, and he was always grumbling, despite the fact that the other creatures of the wood really went out of their way to be kind to him. Eeyore's reply to a morning greeting is typical. 'Good morning,' said Eeyore. If it is a good morning, he said. 'Which I doubt,' said he. 'Not that it matters,' he said.

Eeyore, melancholy old donkey that he was, was sadly out of tune with his environment. He was maladjusted, to use a modern but expressive term. Something must have happened to him in some forgotten corner of his childhood that prevented him from getting along with people as he grew older. Some disappointment had come to him, or some fear had been planted in his mind, or some injustice had built up in him a resentment toward his fellow beings. Perhaps he was shy and sensitive and protected himself from further wounding by a gruff exterior. Perhaps he was a round peg in a square hole, or a square peg trying to accommodate itself to a round hole. Whatever the reason, his personality did not click and he did not have fun like other donkeys, and the pigs and ugars and kangaroos and teddy bears in the book that might have been his friends.

The environment, according to Webster's dictionary, consists of the surrounding conditions, influences or forces that bear on us. When applied to the individual child, this means the small world in which he lives and moves,

and the people in it with whom he must come in contact—in the home and in the school, at work and at play. A happy adjustment exists when the environment, by its nature or by the changes that we are able to make in it, suits the individual, and when the individual, by nature or by the changes that can be made in him, suits his environment.

We must assume, at the start, that all holes are not round, convenient as it would be to have them so, and that pegs come in many odd and uncomfortable shapes. Sometimes we can shape the hole of environment a little or a good deal, depending on circumstances, more often our task is to try and shape the child peg to fit as comfortably as possible into the world that the centuries formed for him.

During the months of the child's infancy, our opportunity to improve his environment is the greatest. We can furnish suitable food for him, we can give him a place to rest and the opportunity to use it, we can modify his formula to meet his needs, we can give him sunlight, cod liver oil and orange juice, we can see that he is not too cold and not too warm, we can keep uncomfortable friends and relatives from him. We can see to it that he has the advantages of comfortable clothes and bedding, and proper soaps and powders and washcloths and towels. In these ways we can alter and improve both his physical and his mental environments.

As he grows older, as he grows farther away from the close, protective environment that we had hitherto been able to furnish for him, our task becomes harder. He is outgrowing us, and one of our greatest mistakes lies frequently in trying to prevent this outgrowing process. When our child was a baby, each detail of his life needed superintendence for his own good. As he matures, we must take care that we do not tie him to our apron strings, that we do not try to keep him in the hothouse environment that his infancy seemed to require.

Less and less, now, can we adapt the environment to the child. We can still see that he has proper clothing and suitable shoes, that his room is occasionally aired and properly warmed, that he has a comfortable bed and a reasonable diet and the correct vitamins, both in number and amount. We can try and furnish him with the right type of play materials, and proper companions, and eventually, so far as it is in our power to select it, the right school. argument. If their companions are planning something that even seems unwise, then let ours do it also, if it is not too bad, for they must not be made too different from their fellows. We must play to them the part that knowledge played in the old interlude, when he said

Everyman, I will go with thee, and be thy guide,  
In thy most need to go by thy side.

## DEATHS

**MURPHY**—EDWARD V. MURPHY, M.D., of Newport, Rhode Island, died March 9. He was in his seventieth year.

Dr. Murphy received his degree from the College of Physicians and Surgeons of Baltimore, in 1899. He was a fellow of the Massachusetts Medical Society and the American Medical Association.

His widow survives him.

**PECK**—ROY H. PECK, M.D., of 15 Temple Street, Springfield, died March 29. He was in his sixtieth year. Born in Burlington, Vermont, he received his early education there. After his graduation from the University of Vermont he attended the Baltimore Medical College and received his degree from the Kentucky School of Medicine in 1903. He took a postgraduate course at Johns Hopkins University and then studied in New York and abroad.

Dr. Peck was a fellow of the Massachusetts Medical Society and the American Medical Society, and was a member of the American Urological Association.

His widow, his mother and a cousin, survive him.

## MISCELLANY

### GOVERNMENTAL AID IN CANCER CONTROL

Patients with advanced cancer who have been treated at the University of California with rays from the cyclotron, the new atom smashing machine, are furnishing much encouragement for scientists in this field, officials of the National Cancer Institute of the United States Public Health Service recently announced.

"Tests have not gone far enough to establish permanent cures," Dr. Ludvig Hektoen, executive director of the National Advisory Health Council pointed out, but the cancerous growths of these patients are receding, and this bit of encouraging evidence of the value of the radio-active particles produced by the cyclotron is leading to further studies and experimentation.

The National Advisory Cancer Council at a recent meeting recommended to the Surgeon General of the Public Health Service that \$23,000 be given to the University of California to help finance special cancer treatment work to be undertaken in connection with a new medical cyclotron. It is expected that the new instrument will be installed at Berkeley, California, next month.

This grant makes a total of nineteen grants aggregating \$159,000 which have been recommended by the council since the National Cancer Institute was created by a Congressional Act of 1937.

Other current activities of the Institute include (1) twenty-two young physicians receiving special training in diagnosis and treatment at approved cancer clinic centers (2) a cancer unit being developed at the United States Marine Hospital in Baltimore to provide additional facilities for an estimated 4000 cases in the next twenty-five years, (3) the granting of fifteen research fellowships for work on projects undertaken by the National Cancer Institute and private research centers (4) five field invest-

gations now under way on the incidence of cancer, its mortality, the epidemiology of the disease with special reference to the deadly lung cancer, the effectiveness of various methods of therapy and the cost of adequate therapy and (5) purchase of 9.5 gm. of radium, delivered to the Bureau of Standards for rigid tests before the supply is distributed to hospitals and clinics throughout the country (only 10 gm. will be retained for the Institute's own work).

During this month staff members of the Institute are co-operating in the nationwide observance of Cancer Control Month, the month of April being set aside each year by congressional resolution and by a presidential proclamation as the time when special attention is given to educational efforts in behalf of the control of cancer, the disease which ranks second in the causes of death in this country and which in recent years has become increasingly serious as a public health problem. *Release (No. 17-6) from the United States Public Health Service dated April 14, 1939.*

### YOUR HEALTH BROADCASTS

The next series of 'Your Health' broadcasts, sponsored by the American Medical Association and the National Broadcasting Company and heard over the Blue Network each Wednesday at 2:00 p. m., is entitled 'Mothers and Children.' It consists of four broadcasts as follows:

#### May 3 Healthier Babies

Daily routine of the healthy baby, medical supervision, feeding

#### May 10 Healthier Mothers.

General advice for the expectant mother, good for girls and boys to know about.

#### May 17 The Doctor's Workshop

The place of the hospital in the health program of individual and community

#### May 24 Toddlers, 1939

The preschool child and the health and personality problems of that age.

### NEW ENGLAND WINNERS IN HEALTH CONSERVATION CONTESTS

The awards for 1938 in the City Health Conservation Contest and the Rural Health Conservation Contest were recently announced by the Chamber of Commerce of the United States and the American Public Health Association. These contests are said to be the most effective means of stimulating adequate health protection and health promotion services yet devised in this country. The awards are made according to the effectiveness with which a community has met its health problems.

In the City Health Conservation Contest the winner in Group II (population 250,000 to 500,000) was Providence, Rhode Island and in Group IV (population 50,000 to 100,000) Newton, Massachusetts. In Group V (population 20,000 to 50,000), Stamford, Connecticut, received an award of merit. Furthermore, Brookline, Massachusetts, and Greenwich, Hartford and New Haven, Connecticut, each received a special award in recognition of the maintenance of previously high standards that were the basis of two or more previous first awards in its respective population group.

In the Rural Health Conservation Contest, awards of merit were given to Barnstable and Berkshire counties, Massachusetts, and in the contest for tuberculosis control Newton, Massachusetts, and Hartford, Connecticut, were tied for first place, with an award of merit going to New Haven, Connecticut.

the child. There is a fortunate tendency today to draw away again from the overstrict training of the baby, that begins almost from the day he is born. We feel now that it is not necessary or even wise, in many cases, to stick too strictly to a regular feeding schedule with a set number of hours between feedings and a set number of feedings a day.

Dr Arnold Gesell, who has contributed so much to the study of infants' behavior in his New Haven clinic, has taught us that the timepiece of a baby's own nervous system and stomach is more valuable to the baby's individual needs than are all the most accurate timepieces in the world. When the baby's stomach begins to contract with hunger pains, he knows that it is time to be fed whether the clock hands stand at eight or ten o'clock, or even if it is at two o'clock in the morning and that particular hour for feeding has been forbidden.

Our tendency has been to start training habits at too early an age, and to pursue them too relentlessly—in insisting on an inflexible adherence to rigid hours of feeding, trying even to insist that an infant must take care of a planned amount of nourishment in a given amount of food, carefully divided into a fixed number of feedings, each of which must be entirely consumed at a stated hour! Bowel training, according to the formula for producing standardized children, must be begun at so many weeks of age and accomplished at so many months, and thereafter there must be no lapses. Bed wetting is forbidden, according to this formula, after the age of two years, and thumbsucking is banned at any age.

Many babies, of course,—perhaps the majority of babies,—will thrive on this regimentation, but Dr Gesell feels that there are other things we can do for them that are more important than a rapid adjustment to a feeding schedule which has been worked out beforehand, a precocious use of the chamber vessel, or an enforced stopping of the sucking reflex. More important, according to this authority, is the development of a sense of security that comes to the infant from being fed when he is hungry, and from being left alone when he is sleepy. Schedule-fixing creates tensions and conflicts that are of considerable importance at this age, and even the best schedule that can be devised for the individual represents a compromise between his make up and the needs of the particular environment into which he is born.

The fundamental principle that I should like to emphasize this afternoon is that each infant—each child—is an individual, reacting differently from others to the same kind of thing, and the greatest help we can give him in the adjustment to his environment—the living world about him—is a sense of physical and mental security.

I have tried to show that, while the infant can carefully and gently be molded to his environment, it is during the years of infancy and early childhood that the most can be done with the environment itself. Of course, our effectiveness with both the child and his surroundings in our attempts to accommodate the one to the other grows steadily less as the years advance. Our protectiveness cannot continue too long, nor is it wise that it should. We have a little longer time to work with the plastic human material than we have with his rapidly expanding world, but even that time is all too short, and we must use it to the best advantage.

We know at best little about the future surroundings in which our child will find himself. Little did our own parents know of the stresses and tensions, the violence and letting loose of the world's passions that were so close at hand when we were born, little did they know of the economic and social changes that were to come and

to which their children would have to adjust themselves. Little do we know of the conditions that our children will have to meet when they leave what protection we have to offer. What we do know—a knowledge that was hardly appreciated a generation ago—is that times are constantly changing and that new and strange conditions are always ahead.

For these changes and for an independent and self-reliant life, the child must be prepared, so far as it is in our power to do so, with thoughtfulness and wisdom and with patience, but with firmness. Dr Gesell summed up this duty of ours when he wrote: "The key to the mental hygiene of childhood lies in building up adequate self-reliance and independence. Even in infancy this principle must be regarded. Not only from the breast must the child be weaned. Slowly but progressively he must attain befitting fortitude and detachment. He cannot always play in his mother's lap, he must in time begin to play on the floor, he cannot always play in the same room with his mother, he must learn to play in an adjoining one—first, for a few minutes, later, for an hour at a time. If the mother must leave the house to hang up the clothes, he must be content to watch her through the window—even though it costs him a struggle. He must even learn to go to bed alone, and later to school alone. Gradually then the shift comes, from adaptation of the environment, even as we train the infant, to intensive training of the child, as the horizon of his environment broadens to such a degree that we cannot do much about it, except occasionally in certain narrow ways."

Here are the things that we must try and do with these children before they finally slip beyond our immediate influence—and if we are successful, our influence will guide them through their lives. We must try by precept and example, and more by the lives we lead ourselves than by any lectures we are capable of giving, to teach to them nervous and emotional stability and calmness of mind under adverse circumstances. If they are masters of themselves, they cannot be mastered in mind or spirit by their surroundings. If they have inner resources, they cannot become prey to the doubts and fears and indecisions that will beset them, nor can they fall heir to the boredom of not knowing what to do when the art and literature of the ages and the mysteries of science and the wonders of nature are constantly beckoning about them.

We must try ourselves, as hard as we possibly can, to be the kind of persons we want our children to be. Without self-control we cannot teach self-control—without peace of mind we cannot show them the value of calmness and fortitude. You cannot shout at a child to make him quiet and have your words effective.

We must cut to a proper level the amount of outside stimulation that our children are to receive, and try to make sure that it is of a suitable type. The shaping of some of these influences in developing the character of our future American men and women presents a direct challenge to the motion picture and radio industries. We must find out and provide the best play materials for developing ingenuity and inner resourcefulness, we must at least expose our children to the best music, and do it seriously, in the hope that that particular contagion will take, we must see that they have available the best books and best magazines, and encourage their use in order that reading for pleasure must not become a lost art, we must allow their personalities to develop, even if this development at times seems unsound to us. If we must argue with our children, let them at times win the

Treatment by bouginage was carried out at various times, but with only temporary improvement. After the first attempt at dilatation the patient complained of substernal pain, but showed a normal temperature, pulse, respiration and blood count. After bougies and esophagoscopes had been passed several times, the Tucker dilator was resorted to. A pressure of 5 pounds was used the first time. The patient did well, gaining 20 pounds during the following two months. During this period an afebrile inflammation of the upper lobe of the left lung appeared, but cleared up by spontaneous absorption. Before discharging the patient, the Tucker dilator was used once more, this time at a pressure of  $8\frac{1}{2}$  pounds. On the same evening the substernal pain reappeared. Within thirty six hours the temperature rose to  $103^{\circ}\text{F}$ , and the white blood-cell count to 10,200, later to 18,000. On the fourth postoperative day the roentgenologist reported a shadow suggestive of a subdiaphragmatic abscess, and an abscess of the lesser omental cavity was evacuated. Two days after this the patient died of peritonitis. Autopsy revealed a perforation on the posterior wall of the stomach, about 5 cm. below the cardiac orifice. Another small area was nearly perforated. A diagnosis was made of spontaneous rupture of the stomach due to a weakening of the stomach wall by a previously existing pathologic condition. The author believes that the latter contributed to the development of the cardiospasm.

**Discussion** Dr Mosher stated that 8 pounds was too much pressure to use and that he had found that strictures do not require such high pressure.

**POSTOPERATIVE TONSILLAR HEMORRHAGE.** Dr John R. Noyes, Brockton, Massachusetts.

After reviewing the various hemostatic procedures of the past and present, the author described a method that has yielded excellent results in 126 cases during the past eighteen years. After cleaning out the tonsillar fossa and locating the bleeding point, 0.5 cc. of a 10 per cent novocain solution, containing 1 minim of adrenalin in each cubic centimeter, is injected around it. If the bleeding point cannot be found it is best to inject various areas. Up to 10 cc. of the solution can safely be used. The author believes that the mechanism of the hemostasis under this treatment is the pressure exerted by the injected fluid plus the vasoconstrictor action of the adrenalin.

**Discussion** Dr George L. Tobey cited a case of bleeding into the tissues of the soft palate. All procedures to stop the hemorrhage had failed. At the time of this discussion he was considering the possibility of having to tie the external carotid artery. Dr August L. Beck stated that he prefers to place his trust in the bipolar diathermy apparatus. Dr Lyman G. Richards lamented the fact that so little is known about the cause of postoperative bleeding from the tonsillar fossa. He had found the determination of the bleeding and clotting times were of no help and stated that primary hemorrhage can be the fault of the operator, secondary bleeding not.

**PRECAUTIONARY MEASURES IN PARANASAL SURGERY UNDER LOCAL ANESTHESIA.** Dr William H. Chaffers, Lewiston, Maine.

The author cited the case of a young physician who was twice treated for an obscure, painful eye condition. Routine examination revealed a sessile tumor on the border and lateral surface of the right inferior turbinate. This proved to be a calcium-encrusted cotton tampon. Finally it was learned that nine years previously the patient had been operated on for a dentigerous cyst of the maxilla and

that cotton tampons had been placed into the nostril of that side. One of these had been overlooked and it remained in the nose, giving rise to coryza like symptoms and slight respiratory obstruction. Some years previously the author, while doing a secondary Caldwell-Luc operation, removed a cotton tampon from the antrum. This tampon probably necessitated the secondary operation by interfering with healing.

The author stressed the importance of thoroughness in history taking regardless of whether the patient be layman or physician. He also said that he considers it advisable to institute tampon counts, just as the general surgeon insists on sponge counts.

**APPLIED BIOCHEMISTRY IN THE ETIOLOGY AND TREATMENT OF CLINICAL CONDITIONS OF THE NASAL ACCESSORY SINUSES.** Dr DeForest C. Jarvis, Barre, Vermont.

The author stated that he believes that in many cases certain foodstuffs can give rise to nose and throat conditions with which every nose and throat specialist is confronted daily: excessive watery or mucopurulent nasal secretion, enlarged turbinates and a pharynx with large lateral bands and lymph follicles. These conditions are, in the author's opinion, due to what he terms 'a block in the body process of cell oxidation.' The offending foodstuffs the author has found to be wheat, graham and buckwheat flour, white and brown sugar, and citric acid as found in citrus fruits. For these rye flour, oatmeal, cornmeal, honey, bananas and apple juice are substituted. For the most efficient utilization of these foodstuffs in the body cells it is necessary to supply oxidizing minerals such as iodine, iron, copper, manganese and arsenic, all in organic form. The mineral content of the blood determines the rate at which the blood sugar is burned. In the author's opinion the American diet is very low in mineral ash. The treatment of such conditions brought about by a 'block in the body process of cell oxidation' is directed, first, to the establishment of a proper diet and, second, to the administration of an oxidizing catalyst in the form of insulin. Of this latter the patient is given 3-unit doses subcutaneously whenever he presents himself for examination. In addition the patient is instructed to take 3 drops of Amend's iodine solution twenty minutes before meals. Under this form of treatment, cases of acute sinusitis usually clear up in three days, subacute cases require ten days, and chronic cases six to twelve months. The author cited 2 typical cases which responded promptly under the treatment described.

**HEARING AIDS BY A WEARER OF ONE.** Miss Elsie L. Staples, Boston.

The speaker discussed the use of hearing aids from the standpoint of the wearer. She strongly advised that hearing aids be resorted to before the deafness had progressed too far. Most persons receive but little help from a hearing aid until the hearing loss amounts to from 30 to 35 per cent, but when that point has been reached no further delay should be tolerated. No otologist should allow his deaf patients to struggle along until they have stopped trying to hear. At this point the speaker related how not one of the otologists whom she had consulted for the possible treatment of her deafness had called her attention to the use of lip reading or a hearing aid. It was her oculist who did that. The somewhat complex psychology of the deaf was discussed in some detail. Thus it makes a great deal of difference whether or not a deaf person hesitates to ask for the repetition of sentences or phrases. Some want to carry on their wonted activities, others resign themselves

## MIDDLESEX UNIVERSITY

Dr Stephen Rushmore, chairman of the Approving Authority on Medical Education, Dr Domizio A. Costa, member of the Board of Registration in Medicine, and Dr William H. Blanchard, surgeon-in-chief of the Captain John Adams Hospital, were the principal speakers at the annual banquet and ball of Middlesex University on April 13 at the Hotel Statler. Dr Rushmore complimented the trustees of Middlesex University on the prompt acceptance of the suggestion of the Approving Authority that the requirements for admission to the junior-college premedical course be raised so as to exclude high school graduates with less than a B average in college preparatory courses. In conclusion he said "It is my wish for your institution and for yourselves that you may strive worthily and justly and that you may receive the just reward of your striving." Dr Costa spoke on the history and functions of the Board of Registration, and Dr Blanchard discussed the position of the physician and of medical schools in the economic world of today.

Guests at the head table included the following physicians: Dr Alonzo Shadman, superintendent of the Forest Hills Hospital, Dr Edward J. Dailey, superintendent of the Central Hospital in Somerville, Dr Martin L. MacDonald, president of the Alumni Association of Middlesex University, and Dr Horatio S. Card, secretary, and Dr Frank L. Whipple, vice president, of the trustees.

## NOTE

The following awards, for study at the Harvard Medical School during the coming academic year, were recently announced: Victor Emmanuel Chapman Memorial Fellowship to Henri Debidour, of Paris, France, Jeffries Wyman Scholarship to Don W. Fawcett 1M, of West Branch, Iowa, Daniel A. Buckley Scholarship to William J. Baker 1M, of Cambridge, Frederick E. Parlin Scholarships to Irving M. London 4C and Irving L. Pavlo 3M, both of Malden, Massachusetts.

## CORRESPONDENCE

## A CHALLENGE

*To the Editor* It is indeed time to correct a misstatement which, for six or seven years, Dr Morris Fishbein has been repeatedly making in his arguments for the status quo of American medicine, including his latest contribution to the *Journal* namely, that the American Medical Association is a democratic organization with its corollaries, that the House of Delegates is representative of its membership and that the policies of the present management meet the approval of the majority of the members of the American Medical Association. The obvious untruth of these declarations of his is manifest from the following facts:

- 1 The voting for councilors by the constituent societies is not done by means of secret ballots.
- 2 The list of councilors presented by the nominating committees contains few names not of members past middle age who have served as officers in their district societies.
- 3 Only a small proportion of the members of the district societies attend even the meeting for the annual election of officers.
- 4 The delegates to the House of Delegates are chosen by the councilors, who at best represent only the oldest of the three age groups of members, some of whom have retired from practice.

- 5 The so-called Hunt Plan for local health councils, heartily endorsed by the Council of the Society, was decisively rejected by his own district society.
- 6 The older men in the Council include the most successful of their medical generation and are therefore satisfied with the present conditions of practice and ready to approve measures to prevent any change.
- 7 Many members of the district societies belonging to societies for specialists with no real interest in the American Medical Association are constrained to become fellows in the American Medical Association in order to retain their good standing in their respective special societies.
- 8 The *Journal of the American Medical Association* fails to provide a forum for the free and open discussion of mooted questions, contrary to the principles underlying any democratic organization.
- 9 There was a revolt against the clique that managed the American Medical Association before the transfer of the headquarters to Chicago and the general housecleaning at that time.

I challenge the present management of the American Medical Association and the House of Delegates to permit the members to vote by postal cards their approval or disapproval of the retention of those leading spokesmen who have brought such disrepute upon organized medicine.

G. W. HAIGH, M.D.

242 Burncoat Street,  
Worcester, Massachusetts

## ERRATUM

*To the Editor* In a paper read by me before the Massachusetts Medical Society in Boston on May 31, 1938, and published in the *New England Journal of Medicine* on September 8, 1938, I inadvertently made a very foolish blunder.

The last sentence of the last complete paragraph in the first column on page 335 ends as follows: "354 patients with some sort of peritoneal involvement, with 20 deaths, a mortality of 5.6 per cent." The number "354" appears earlier in the same paragraph, and was carelessly repeated. The section should read: "271 patients with some sort of peritoneal involvement, with 20 deaths, a mortality of 7.4 per cent."

ARTHUR M. SHIPLEY, M.D.

University Hospital,  
Baltimore

## REPORTS OF MEETINGS

## NEW ENGLAND OTOLOGICAL AND LARYNGOLOGICAL SOCIETY

The following are abstracts of the papers presented at the November 15, 1938, meeting, in Boston, of the New England Otolological and Laryngological Society.

**A CASE OF CARDIOSPASM WITH AUTOPSY REPORT** Dr. Harry Butler, Bangor, Maine.

A twenty-nine year-old woman with a history of cardiospasm was referred to the author. Medical examination and roentgen ray studies had failed to show any cause for regurgitation of food over a period of two years, other than fibrosis of the lower end of the esophagus. The esophageoscopic picture was typical of cardiospasm.

and that there have been four or five such cancers of the small bowel at the hospital during the past several years.

The second case, presented by Dr. James Hawkins, was also from the medical service. A forty-seven-year-old Italian-born waiter was admitted on December 17, 1938, with a chief complaint of nausea and vomiting, together with pain in the epigastrium two fingerbreadths above the umbilicus, of three weeks' duration. The patient was first seen in 1931 in the outpatient department for hemoptysis, a productive cough and chest pain, of two weeks' duration. He had a history of four or five years of similar symptomatology, having had pneumonia in 1922. He had had epigastric discomfort and vomiting since 1918. This vomiting was characterized by being easily brought on and the vomitus often contained food material ingested eighteen to twenty hours before. At that time the patient was referred to the hospital for x-ray study, which showed consolidation of the right lower lobe with abscess formation and calcification. He was treated for three months with arsphenamine, and then with neoarsphenamine, with improvement of his condition. He felt well and had only a moderate cough and no acute episodes until September, 1935, when he returned with pain in the left lower quadrant, constipation and mucus in the stools. This gradually cleared up with conservative treatment. In December, 1937, he had pain two fingerbreadths above the umbilicus, coming on one hour after meals and markedly relieved by treatment with tincture of belladonna and a Sippy diet.

In December, 1938, a recurrence of the pain proved intractable to treatment with a Sippy regime and antispasmodics. An x-ray film taken at that time revealed cardiospasm and irregularity of the duodenal cap. The patient was referred to the hospital, complaining of pain and regurgitation. Physical examination revealed relative dullness over the right base with bronchovesicular breathing and occasional rales over both bases medially. The abdomen was negative except for a palpable cecum and descending colon. He was put on a soft solid diet without improvement. X-ray films of the chest showed no change. Bronchoscopy revealed no obstruction of the bronchi, merely calcified nodes. Esophagoscopy revealed no lesion, and a gastrointestinal series demonstrated a duodenal ulcer, in addition to coarse rugae and some evidence of inflammation of the lower end of the esophagus. Esophageal lavages were instituted, with improvement in the patient's symptoms.

Dr. Emery, in commenting on the case, described it as being unusual in having three common conditions at one time—duodenal ulcer, cardiospasm and lung abscess. It suggested to him three interesting questions: Was the lung abscess secondary to the cardiospasm, as a result of inhalation of food? Did the ulcer exert a detrimental effect on the cardiospasm? What was the significance of the unusual esophageal dilatation, which was more pronounced in the upper half than at the lower end?

Dr. Cutler accounted for the x-ray picture by stating that the once dilated esophagus was contracted as a result of irritability. He suggested a diagnosis of acute esophagitis due to aberrant gastric mucosa, based on references and his personal experience. Dr. Emery pointed out that this had been considered but that no hydrochloric acid had been found in the esophagus. Dr. Chester Jones's comment was that the story of a mucous colitis was a common finding in cardiospasm, and that after years of persistence, cardiospasm does give a picture of esophagitis. Dr. John Homans questioned the veracity of the x-ray because of the queer twist of the esophagus at its lower end.

Dr. Emery introduced Dr. W. Osler Abbott, of the University of Pennsylvania, as the speaker of the evening. The

subject was 'The Role of Intubation in the Study and Treatment of the Small Intestine.' Dr. Abbott briefly described the historical development of intubation, illustrating with lantern slides.

The first intubation of the gastrointestinal tract was performed and described in 1813 by a Philadelphian, Dr. Philip Physick, who went to the rescue of two children who had swallowed laudanum, one forty minutes after the other. He catheterized their stomachs and was able to save the first, but the second child died. In 1909, Dr. Grodigen observed a fowl swallow a length of string, and shortly thereafter was able to see both ends of the string. He immediately experimented on a child on his pediatric service and obtained the same results, although it took a number of days to consummate the exit. Others tried similar experiments.

There are three main principles involved: first, an aspiration tube, second, a thin-walled rubber balloon at its tip upon which peristaltic action can exert a force, and, third, a separate accompanying tube, or a septal division of the aspirating tube, to inflate or deflate the balloon at will. Dr. Abbott took a very minor share of the credit in this study to himself, naming several co-workers.

A study was made of the content of the fasting small intestine in a volunteer human subject, and a chart of the reaction and osmotic pressure was shown. The reaction of the duodenal contents is not so alkaline as statements have led one to believe. By samples taken at different distances down the intestine, it was found that the pH gradually approaches that of the blood, and although some readings were higher, the average readings at any stated level never reached pH 7.4. Three hundred milliosmols per liter being taken as the osmotic pressure of the blood, it was found that in the duodenum the contents were hypotonic and rose almost to blood level lower down in the intestine. Practical aspects of this study have a bearing on the problem of how to alter the reaction of intestinal contents as, for instance, in anemia, where it is well known that iron is better absorbed in an alkaline medium. It was recognized that the condition of the bowel contents is dependent on the activity of the bowel as much as on its secretions. When hydrochloric acid was given by mouth, the rate of flow remained unchanged whereas the pH rose. When sodium bicarbonate was given by mouth, even far down the intestine a striking increase in rate of flow was demonstrable, together with a rise in pH. This explains the laxative effect of soda. Higher concentrations of soda solutions had no effect, and water given alone increased the rate of flow slightly and lowered the pH. When glucose was given in a wide variety of concentrations and amounts, it was found that the concentration of glucose recovered by the aspiration tube in the jejunum and ileum was always below 54 gm. per 100 cc., that is, isotonic, except when the subject received a tumbler full of pure syrup. The rate of flow in the intestine was much increased by the ingestion of glucose. Since it had been found that the intestinal osmotic pressure was quite stable in spite of a descending decrease in glucose concentration, determinations of chloride concentrations were carried out, which demonstrated a descending increase to balance the glucose decrease.

The absorption of glucose from the gastrointestinal tract offered itself as the next subject for study. The first observation, based on the figures above, was that the more dilute solutions were better absorbed. In this study, a three lumen tube was used and at least two balloons, thus simulating the experiments with surgically isolated loops of bowel in animals but being much nearer the normal state by isolating lengths of bowel between any two inflated balloons. This method seems to be technically re-

to be more or less cut off from the rest of their fellow beings

The various forms of hearing aids, electric or non-electric, were described and discussed. One fact must be borne in mind: there is no "best" hearing aid. Not only must the type and degree of the deafness be considered, but many other factors come into play to make a hearing aid useful to one patient and useless to another. A properly fitted hearing aid must not only increase the power of the sounds transmitted but must also avoid distortion and adventitious noises. Clarity is just as important as loudness. The need for fighting unethical advertising on the part of manufacturers and dealers is obvious, for the deaf have always been a ready prey for those who promise them relief. The Boston Better Business Bureau has recently taken action to stop such advertising. Although hearing aids can transform the deaf into useful, happy individuals, it must be remembered that they have definite limitations. They do not raise the hearing level to anywhere near the normal points. Lip reading must always be ready to do its share in filling in the gaps left by the hearing aid, especially in the transmission of consonants. Finally the speaker reminded the audience of the services rendered by the Boston Guild for the Hard of Hearing as a clearing house on all phases of deafness.

**Discussion.** The paper was discussed by Drs. Mosher, MacCready, Hill and Tobey. It was said that it was one of the pleasantest on this subject ever given and that it cleared up a great many points as to the uses of hearing aids.

**SURGICAL TECHNIC FOR THE CONSERVATION OF THE HEARING IN CHRONIC MASTOIDITIS** (This paper appeared in full in *The Laryngoscope* for July, 1938.) Dr. J. Morris Smith, New York City (by invitation).

The author stated that he believes that it is impossible to deal with all cases of chronic mastoid infection by the use of one type of operation. The degree of necrosis encountered in the different cases should determine the surgical technic employed. Four types of procedure are recommended.

The complete simple mastoid operation is indicated where the removal of the drum and ossicles is not necessary. It consists essentially of the usual simple mastoidectomy plus a wide exposure of the attic by dissection of the bone at the root of the zygoma. The middle ear is cleaned of polypi or granulations through the external canal. The aftertreatment consists of cleansing irrigations from the mastoid wound, as well as from the canal. This technic, which is especially indicated in young children, will frequently result in a dry ear, with the preservation of valuable hearing.

The second technic differs from the first in that the incus is removed in order to facilitate the removal of granulations from the attic. The author claims that the removal of the incus has remarkably little effect on the hearing.

In cases where the hearing in the other ear has been lost, or in the presence of an extensive bilateral infection where the preservation of the hearing may be vitally important, the third technic is employed. This the author calls the new radical operation. It is devised to care for some of the cases requiring removal of the malleus and the incus without, however, necessitating the complete radical operation. The technic is as in the second type except for the removal of the malleus and the remaining portions of the drum membrane. The external canal and its lining are left intact. The aftertreatment includes irrigations and careful drainage. In the author's opinion

this operation will be successful in many cases in which formerly the complete radical operation would have been used.

The complete radical operation is resorted to in complicated cases or where one of the above procedures has failed to check the progress of the disease. Ossiculectomy is not advised, since it leaves the operator as well as the patient in the dark concerning the extent of the necrosis beyond the attic.

#### HARVARD MEDICAL SOCIETY

A meeting of the Harvard Medical Society was held at the Peter Bent Brigham Hospital, Tuesday evening, January 10, Dr. E. Stanley Emery presiding.

The first case from the medical wards was presented by Dr. J. C. Nunemacher. The patient, a seventy-year-old man, had been admitted two weeks previously with a complaint of increasing diarrhea and edema of the legs. His history went back to 1930, at which time he had mild constipation. In 1931 he developed slight nausea and vomiting, and in 1932 added the symptom of diarrhea. A year later, in December, 1933, abdominal pain and distention set in. The pain occurred first above the umbilicus, then below, and became more severe. During bouts of twelve to fifteen hours duration, the patient vomited once an hour, the vomitus being fecal in character. At that time he was admitted to the surgical service of the hospital. Physical examination revealed marked dehydration, distention of the abdomen and visible peristalsis. An x-ray film revealed small bowel obstruction. At operation 165 cm. of ileum was resected, following a diagnosis of tumor. The pathological report stated that the lesion was a carcinoid, with some malignant degeneration of the cells and with metastases to the mesentery. The patient was discharged after a slow convalescence, and subsequently did well.

In 1936 and 1937, a gastrointestinal series and a barium enema were negative. In 1938, a mass in the right lower quadrant the size of an orange was made out, which by June had increased its diameter to 10 cm. and was accompanied by increasing diarrhea and edema of the legs. The patient was admitted to the medical service at that time. For two and a half months every form of treatment was unavailing, and he had been discharged three weeks previously.

A week later he was again readmitted, feeling very weak. Four injections of mercupurin within a month's time had given him some relief. Physical examination revealed a blood pressure of 140 systolic, 90 diastolic, a systolic apical murmur, shifting abdominal dullness, a mass in the right lower quadrant thought to be an enlarged liver, and a mass in the left upper quadrant which might have been the spleen, since its surface was smooth. He had several telangiectases on the abdomen and purpuric spots on the back. The urine showed albumin, a specific gravity of 1.030, occasional white cells and numerous casts. The blood hemoglobin was 80 per cent, the red-cell count 4,000,000, and the white-cell count 6000. His stools were light yellow, mushy, but showed no occult blood.

Dr. Elliott C. Cutler asked whether the medical service considered the present condition to be due to the tumor or to some accessory factor. Dr. Emery replied that he thought it was a continuation of the same disease that had caused operation. He mentioned the fact that the case was an unusual one in that such tumors were not usually considered malignant and put the question as to why this tumor should produce diarrhea. Dr. Cutler stated that this type of tumor was not so rare as surgeons usually believe.

and that there have been four or five such cancers of the small bowel at the hospital during the past several years.

The second case, presented by Dr. James Hawkins, was also from the medical service. A forty-seven-year-old Italian-born waiter was admitted on December 17, 1938, with a chief complaint of nausea and vomiting, together with pain in the epigastrium two fingerbreadths above the umbilicus, of three weeks duration. The patient was first seen in 1931 in the outpatient department for hemoptysis, a productive cough and chest pain, of two weeks duration. He had a history of four or five years of similar symptomatology, having had pneumonia in 1922. He had had epigastric discomfort and vomiting since 1918. This vomiting was characterized by being easily brought on and the vomitus often contained food material ingested eighteen to twenty hours before. At that time the patient was referred to the hospital for x-ray study which showed consolidation of the right lower lobe with abscess formation and calcification. He was treated for three months with arsphenamine, and then with neoarsphenamine, with improvement of his condition. He felt well and had only a moderate cough and no acute episodes until September, 1935, when he returned with pain in the left lower quadrant, constipation and mucus in the stools. This gradually cleared up with conservative treatment. In December, 1937, he had pain two fingerbreadths above the umbilicus, coming on one hour after meals and markedly relieved by treatment with tincture of belladonna and a Sippy diet.

In December, 1938, a recurrence of the pain proved intractable to treatment with a Sippy regime and antispasmodics. An x-ray film taken at that time revealed cardiospasm and irregularity of the duodenal cap. The patient was referred to the hospital, complaining of pain and regurgitation. Physical examination revealed relative dullness over the right base with bronchovesicular breathing and occasional rales over both bases medially. The abdomen was negative except for a palpable cecum and descending colon. He was put on a soft solid diet without improvement. X-ray films of the chest showed no change. Bronchoscopy revealed no obstruction of the bronchi, merely calcified nodes. Esophagoscopy revealed no lesion, and a gastrointestinal series demonstrated a duodenal ulcer, in addition to coarse rugae and some evidence of inflammation of the lower end of the esophagus. Esophageal lavages were instituted, with improvement in the patient's symptoms.

Dr. Emery, in commenting on the case, described it as being unusual in having three common conditions at one time—duodenal ulcer, cardiospasm and lung abscess. It suggested to him three interesting questions. Was the lung abscess secondary to the cardiospasm, as a result of inhalation of food? Did the ulcer exert a detrimental effect on the cardiospasm? What was the significance of the unusual esophageal dilatation, which was more pronounced in the upper half than at the lower end?

Dr. Cutler accounted for the x-ray picture by stating that the once dilated esophagus was contracted as a result of irritability. He suggested a diagnosis of acute esophagitis due to aberrant gastric mucosa, based on references and his personal experience. Dr. Emery pointed out that this had been considered but that no hydrochloric acid had been found in the esophagus. Dr. Chester Jones's comment was that the story of a mucous colitis was a common finding in cardiospasm, and that after years of persistence, cardiospasm does give a picture of esophagitis. Dr. John Homans questioned the veracity of the x-ray because of the queer twist of the esophagus at its lower end.

Dr. Emery introduced Dr. W. Osler Abbott, of the University of Pennsylvania, as the speaker of the evening. The

subject was 'The Role of Intubation in the Study and Treatment of the Small Intestine.' Dr. Abbott briefly described the historical development of intubation, illustrating with lantern slides.

## ON DOCTORS

## HONY ORCHESTRA

Rehearsals of the newly organ-  
ized Boston Doctors' Symphony  
Orchestra, conducted by Nicolas  
Slonimsky, are held every Thurs-  
day evening at 7 30 at Hampton  
Court Hotel, 1223 Beacon Street,  
Brookline.

Membership is still open All  
physicians, dentists and medical  
and dental students who are inter-  
ested should communicate with  
Dr Julius Loman, Pelham Hall  
Hotel, Brookline (BEA 2430)

## IN T BOTTOMLEY MEDICAL SOCIETY

The next meeting of the John T Bottomley Medical  
Society of the Carney Hospital will be held on Tuesday,  
May 2, at 11 30 a. m. Dr H Boruchoff will speak on  
'Visual Aids of Marked Impairments of Sight.'

WILLIAM J MACDONALD, M D, *Secretary*

## ULKNER HOSPITAL

## CLINICOPATHOLOGICAL CONFERENCE

The monthly clinicopathological conference of the  
Ulknier Hospital will be held on Thursday, May 4, at  
10 p m There will be a discussion of cases by Drs  
E Barton and J R Torbert.  
Physicians and medical students are cordially invited  
attend

## JOSEPH H. PRATT DIAGNOSTIC HOSPITAL

Bennet Street, Boston  
Auditorium, 9-10 a m

## MEDICAL CONFERENCE PROGRAM

Tuesday, May 2—Diagnosis of Certain Hip Conditions  
Dr J D Adams.  
Wednesday, May 3—Hospital Case Presentation. Dr  
R. W Buck.  
Thursday May 4—The Management of Bleeding in Ob-  
stetrical Cases Dr A K. Paine  
Friday May 5—The Management of Chronic Alco-  
holism. Dr Merrill Moore.  
Saturday, May 6—Hospital Case Presentation Dr S J  
Thannhauser  
Sunday, May 9—Gastrointestinal Clinic, Ulcerative Co-  
litis. Dr K. S Andrews and Dr H H. Lerner  
Wednesday, May 10—Hospital Case Presentation Dr  
S J Thannhauser  
Thursday May 11—Macrocytic Anemia and Liver Thera-  
py Dr W P Murphy  
Friday May 12—Medical Aids to Crime Detection Dr  
E A Hill

Saturday, May 13—Hospital Case Presentation Dr S J  
Thannhauser

Tuesday, May 16—Roentgenological Diagnosis and Dif-  
ferential Diagnosis of Bone Tumors Dr Richard  
Schatzki.

Wednesday, May 17—Hospital Case Presentation Dr  
S J Thannhauser

Thursday, May 18—Recent Advances in Electrocar-  
diography Dr H. Magendantz.

Friday, May 19—Some Clinical Aspects of Heart Dis-  
ease. Dr Reginald Fitz.

Saturday, May 20—Hospital Case Presentation Dr S J  
Thannhauser

Tuesday, May 23—Hemoglobin, Iron, Bilirubin Dr  
George Barkan.

Wednesday, May 24—Hospital Case Presentation Dr  
S J Thannhauser

Thursday, May 25—Rheumatism Presentation of cases  
Dr Walter Bauer

Friday, May 26—Recent Advances in the Understanding  
of Gastric Secretion Experimental and clinical ob-  
servations Dr Oliver Cope.

Saturday, May 27—Hospital Case Presentation. Dr S J  
Thannhauser

## MASSACHUSETTS SOCIETY FOR SOCIAL HYGIENE

The annual meeting of the Massachusetts Society for  
Social Hygiene will be held at the Hotel Sheraton, on  
Wednesday afternoon, May 3, at 4 o'clock.

Mr W Linwood Chase, headmaster of the Country Day  
School for Boys in Newton, will speak on 'Sex Educa-  
tion The school's responsibility to the home and the  
child'

Dr George G Smith will present the annual report, and  
Mr George N Northrop, headmaster of the Roxbury  
Latin School, will give a brief report for the Committee  
on Sex Education in the School Program. Tea will be  
served

## CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY, MAY 1

### MONDAY MAY 1

4 p m Physicians and medical students are cordially invited to  
attend a clinic presented by the medical surgical and orthopedic  
services of the Infants and Children's hospitals in the amphitheater of the Children's Hospital

liable. Kymographic tracings through these balloons were taken concomitantly. It was found that, with increasing concentrations of glucose placed in an isolated bowel segment, the amount recovered after a certain period of time increased and that isotonic solutions produced normal bowel activity, which became hyperactive on giving hypotonic glucose. The fact that the rate of glucose absorption, as measured by plotting a curve of different concentrations given, was found to be about 1 gm in fifteen minutes, together with the first observation that reduction in recoverable concentrations is very rapid as one goes down the bowel and that even in the jejunum this reduction is marked, implies that absorption mainly occurs above the latter segment. The rate of admission of contents into the small intestine and the rate of absorption therefrom being fixed, we must assume that the old idea that glucose is not absorbed from the stomach is no longer tenable. However, what was concluded from this study confirms the old theory namely, that absorption occurs by diffusion and also by a special mechanism whereby it occurs more rapidly from dilute solutions than can be explained on a basis of diffusion alone. Practical aspects of this study, in deranged absorption, have been reported by Groen, of Amsterdam.

The use of intubation in studying the action of drugs is apparent. The investigators chose morphine for their subject and checked with fluoroscopy their findings by aspiration and by balloon tracings. The average clinical dose of the drug was injected in the deltoid muscle (a control of plain water being given in certain cases), whereon the tracing from the duodenum showed an intense contraction which lasted twenty to forty minutes, followed by a relaxation which reached its maximum and remained for about one hundred and sixty minutes. Normally the duodenal tracing showed a slightly greater amount of activity than that from the ileum. In this experiment, the ileum showed at the same time only a slight increase in tonus, and the lower ileum traced queer alternate periods of relaxation and contraction. Morphine, then, increases the duodenal resistance and the gastric contents are held back, in about thirty minutes the duodenal resistance decreases, the gastric contents spill over, and the jejunal flow is less steeply downhill toward the lower bowel. On this basis it is possible to explain the death of one of Dr. Physick's patients while the other lived the latter was intubated at least forty minutes after the former!

Intubation is useful in gastroenterostomy. Whereas formerly there was the problem of starvation of the patient as a result of edema of the wound, now the surgeon can place the double lumen tube before completing the sutures, and after the operation is ended the patient can have the stomach contents aspirated, and at the same time be fed by a tube which goes 30 cm into his small intestine.

The most important use of intubation is in the field of intestinal obstruction. Brinton, fifty years ago, claimed there was no such thing as reverse peristalsis (except above the ligament of Treitz), and Dr. Abbott and his associates think that he is right. In addition to finding that the tube with the balloon at its tip was easily carried down by peristaltic action to the point of obstruction, the investigators had an opportunity to observe an obstructed patient who had been given barium by mouth by mistake. The conclusion is that reverse peristaltic waves are in fact, reflected waves. An analogy was made with a piston, its center bored through to form a ring, moving downward in a cylinder. As it moves down next the wall of the cylinder, the contents are displaced upward in a central

stream. So with intestinal contents above an obstruction. By means of intubation tracings it was also found that moderate distention of the bowel increases peristaltic action but that pathologic distention stops it, except in the case of intestinal obstruction due to irritation from outside the bowel, which produces spasm.

Dr. Abbott next reported three of his cases of intestinal obstruction to emphasize the extent of the therapeutic value of intubation in the emptying of the distended gut and the removal of the obstruction. Surgery, as the earliest form of treatment for intestinal obstruction, had a mortality of roughly 40 per cent. The Wangenstein tube reduced this figure to about 25 per cent, but it was ineffective in deflating below the obstruction and did not provide for giving the patient nutriment. The method of intubation has attacked these latter problems.

The first case described had had a five-day history of paralytic ileus with tremendous distention. No benefits were obtained by duodenal suction, and an exploratory laparotomy was likewise unsuccessful. The patient was intubated and deflated and was then fed glucose. He convalesced uneventfully.

The second case was that of a forty-seven-year-old laborer, who came in with perforated ulcer. He had a temperature of 104°F, was distended and had peritonitis and a hemolytic streptococcal septicemia. He was intubated under the fluoroscope. After seven days his bowels moved, but his abdomen became riddled with localizing abscesses. He practically recovered and then came down again with distention, vomiting and signs of obstruction. He was again intubated, deflated and made comfortable. The site of obstruction was then demonstrated by barium passed in by the tube,—a seemingly heretofore procedure which is no longer contraindicated because the heavy barium can be readily aspirated out after the demonstration,—and the abdomen was opened and the binding adhesions divided surgically.

The third case reported had an eight year story of ileitis and included five operations, the details of which were not known. This time the patient had been partially obstructed for a week, and completely so for three days. He had constant fecal vomiting and tetanic convulsions, and his lower extremities were cyanotic as in partial collapse. The patient was intubated and thirty-six hours later, when he was brought down to be fluoroscoped, he was reading the paper. The barium passed in by tube demonstrated a former ileocolostomy, and soon after, a resection of the demonstrated diseased ileitic area was done, the patient at operation being comfortable and in fluid balance. Thus it was shown that not only is intubation of value in deflating distention but also in feeding and in correcting the fluid imbalance, the drainage fluid from the bowel can be measured, allowing a basis for determining replacement therapy.

Dr. Abbott concluded his presentation by discussing results. He said that Dr. Johnson at the Detroit Receiving Hospital had reported a mortality of 93 per cent in cases of obstruction without gangrene so treated. The whole point, of course, is to have the clinical acumen to distinguish between strangulation and non-strangulation. If strangulated hernia can be ruled out, Dr. Abbott believes that most cases may be treated by intubation. As for obstruction in the colon, it can be better treated by cecostomy. Multiple obstruction can be treated to give relief by deflation only down to the first point. Dr. Abbott showed charts illustrating his results. In 47 intubated cases there was technical failure in only 6, and 31 out of 33 serious cases were technically successful.

## BOOK REVIEWS

*Physiopathologie de la Vieillesse et Introduction à l'Étude des Maladies des Vieillards* P Bastar and G-C. Dognotti 235 pp Paris Masson et Cie, 1938 50 Fr fr

This monograph is an attempt to review in a systematic manner the more significant data concerning the morphological and functional changes that occur in old age. The first portion is devoted to an exposition of the significant alterations that can be observed or measured. Each of the major organs is considered in the first chapter. The second chapter deals in a general way with changes in biochemistry, hemodynamics and the special functions (respiration, digestion, urinary excretion and the sensations), and "neurohumoral control." Finally, there is a chapter discussing the significance of the various findings.

The second part deals more directly with diseases of old age. One chapter is devoted to 'senility considered as a disease,' another to diseases common to all ages, a third to arteriosclerosis and diseases peculiar to old age in which the relation is not clear.

The authors main thesis is that most, if not all, the problems of old age resolve themselves, in the last analysis, to a 'loss of capillary reserve' which alters the nutrition and the adaptability of all tissues.

The book is well written in a very simple style. It is well arranged and has a minimum of elaborate data. It is suited to the general reader who is looking for an interesting presentation and interpretation of many of the known peculiarities of old age. For the advanced student and investigator that portion dealing with the measurements of the peripheral circulation will be of particular interest. The authors apparatus for *angiodilatometrie* is described and is very similar to that used recently in this country for the measurement of blood flow in the extremities.

*The March of Medicine Selected addresses and articles on medical topics, 1913-1937* Ray L. Wilbur 280 pp Stanford Stanford University Press, 1938 \$2.75

Doctors and medical students who wish to orient themselves in the general problem of medical education would do well to own this book. As a practicing physician and as president of a great university the author is peculiarly fitted to trace the evolution of medical education in this country from the time when it was virtually a trade to the time when it assumed the definite complexion of a profession in close association with a university.

One finds twenty five years of experience packed within these two hundred and eighty pages. A careful reading of the book shows the author to be not alone the scholar he is but also a prophet of changes which were to come and, in truth, of which we today are a part. There can be nothing but profit for those who will read the addresses entitled "The Future of Medical Education," "Public Health and Human Welfare," "Eugenics," "The Eclipse of Magic," "The Medical Curriculum," "Mental Health as a National Problem," "Keeping the Doctor Up to Date," and "Medicine as a Pacemaker for Civilization." This book should be of absorbing interest to all premedical students, and can be recommended to practicing physicians with enthusiasm and the assurance that they will leave the reading of this book with a mind better prepared for their efforts.

NUMBER 18

## AN ANALYSIS OF THE TREATMENT AND MORTALITY OF THREE HUNDRED AND NINETY CASES OF ACUTE AGRANULOCYTIC ANGINA\*

HENRY JACKSON, JR., M.D.,† AND THOMAS J. G. TICHE, A.B.

BOSTON

**T**HIS paper presents a critical analysis of the efficacy of various forms of treatment in 390 cases of acute agranulocytic angina reported in the literature since 1933. Papers confining themselves to summaries only and not giving actual case histories have not been included, for in such articles the data relative to both diagnosis and treatment are inadequate for proper study.

The evaluation of therapy by a survey of the literature is, of course, open to certain fundamental objections. It must, for instance, be remembered that therapeutic successes are more apt to be reported than are therapeutic failures, but this should be no truer for one type of treatment than for another, so that while the percentage of cures — under any form of treatment — is probably not so great as would appear from such a survey, it is improbable that any one group suffers more from this defect than does any other.

On the other hand, a survey of the existing literature has certain advantages in diseases such as that under consideration. It is impossible in the case of such an uncommon condition to have any one physician collect, in his own right, a series of sufficient magnitude to be of much statistical significance. Furthermore, from a statistical point of view, ten series of 10 cases each in the hands of so many different observers are probably more cogent than 100 cases under one man's control, for the personal element is largely eliminated. In any event, such a survey would seem, at present, the best available method of evaluating the various therapeutic agents so far advocated for this disease.

Leukopenia and neutropenia alone do not con-

stitute the disease acute agranulocytic angina. The efficacy of any therapeutic agent in agranulocytic angina cannot be judged by its effect in other conditions associated with leukopenia and neutropenia, be they ever so marked.

True acute agranulocytic angina, also known as agranulocytosis, malignant granulopenia and acute primary granulocytopenia, may be defined as an acute disease characterized by extreme leukopenia and granulopenia. The red cells and platelets are essentially unaltered. There are very rarely any hemorrhagic manifestations. There are no, or at most extremely few, very immature white cells in the blood at the height of the disease. Neither liver nor spleen is noticeably enlarged, nor is there any lymphadenopathy other than that which may readily be explained by local sepsis. Death may occur within thirty-six hours of the apparent onset. Recovery, if it takes place, usually occurs within two weeks. Relapses occur, though they are uncommon. Rarely the disease is cyclic. While the etiology is still in some doubt, there is general agreement that many cases are caused by amidopyrine, dinitrophenol and similar compounds.<sup>1</sup> The bone marrow shows what appears to be a maturation arrest in the granular white-cell series at the stem-cell or myeloblast stage.<sup>2, 3</sup>

This disease must be sharply differentiated from leukemia with a low white-cell count, aplastic anemia, leukopenia due to overwhelming sepsis and chronic leukopenia due to various causes. This is not the appropriate place to discuss the differential diagnosis.<sup>4, 5</sup>

Of 448 cases reported as agranulocytic angina, 58 must be discarded because a scrutiny of the case reports fails to substantiate that diagnosis and indicates that the proper diagnosis was aplastic anemia, pernicious anemia, overwhelming sepsis, Hodgkin's disease, leukemia or some other funda-

From the Thorndike Memorial Laboratory, Second and Fourth Medical Services (Harvard); Boston City Hospital; the Department of Medicine, Harvard Medical School; and the Collis P. Huntington Memorial Hospital, Boston.

†Assistant professor of medicine, Harvard Medical School; associate physician, Thorndike Memorial Laboratory, Boston City Hospital.

mental disorder associated with chronic leukopenia

Seventy-five of the remaining 390 cases received no treatment aimed specifically at the bone-marrow dyscrasia. Death occurred in 78 per cent of these, a mortality rate essentially the same as that given by other authors.<sup>6,7</sup> It may therefore be concluded, with some degree of assurance, that the mortality when no specific treatment is given is in the vicinity of 75 or 80 per cent.

In order to determine the value of a specific method of therapy, the agent must be given in adequate amounts and sufficient time must be allowed for it to act. If inadequate amounts are administered, or if adequate amounts have been given but the patient succumbs before beneficial action could result, the case must be considered as inadequately treated. The following types of cases must be placed in this class:

(1) Those in which the patients died before the treatment could have had time to influence the bone marrow to renewed activity, as evidenced by the rise of white cells in the peripheral blood. This time interval varies with the particular type of therapy used and will be discussed later.

(2) Those in which the patients recovered or showed unquestionable hematologic response to therapy in a similar time interval.

(3) Those in which the patients died without receiving adequate amounts of a given therapeutic agent, no matter how long they may have been hospitalized.

(4) Those in which the patients recovered under similar circumstances.

It would be expected that the mortality of these inadequately treated cases would be approximately the same as that of a series that had received no specific therapy whatever. This proves to be the case. Of the 130 cases, death occurred in 95, or 73 per cent.

The parenteral use of liver extract was first suggested by Foran, Sheaff and Trimmer.<sup>8</sup> They used a commercial preparation of the "fraction G" of Cohn, and injected the material derived from 100 gm of liver into the vein or muscle every eight hours until a definite rise in the granulocytes or marked clinical improvement occurred. This dose has been accepted as the minimum requirement. Murphy<sup>9</sup> noted that "there was a prompt and often striking response in the number of white blood cells within a few hours of the beginning of treatment." Others have observed this phenomenon, but Witts, Wilcox and Warner<sup>10</sup> point out that there is a definite fall in the leukocyte count in about eighteen hours, and conclude that liver produces a shock-like reaction suggesting peripheral mobilization of preformed cells rather than a stimulation of their production. It has also been claimed that the rise in white-cell

count in pernicious anemia following parenteral liver therapy indicates a stimulating action on the leukocytes, but the relative leukopenia of pernicious anemia is essentially a myelophthisic one, and the slow rise of the white-cell count in this disease under liver therapy is due largely, if not entirely, to the maturation of the immature red cells and the consequent return of the bone marrow architecture to a normal state, thus permitting the unhampered multiplication of leukocytes.

The advocates of liver therapy have set no definite time for the appearance of a favorable response after treatment, but seventy-two hours has been taken as an arbitrary standard, any recovery before this time is regarded as spontaneous, and any death is attributed to inadequate therapy.

Nine cases have been reported in which adequate amounts of liver extract were the only specific therapy used. Eight other cases in which liver extract only was used must be eliminated because of inadequate treatment or because the data presented were insufficient for purposes of analysis. In the 9 adequately treated cases, 7 patients recovered and 2 died, a mortality of 18 per cent.

It would seem from the above figures that liver therapy was definitely successful in the treatment of agranulocytic angina. However, there are 17 other cases reported in the literature in which adequate amounts of liver extract were used together with some other specific method of treatment. If liver were as successful in its effect as the results of the first 9 cases suggest, a similar success would be expected in these 17 cases, since there is no reason to believe that any of the other measures used would interfere with any possible beneficial action of the liver. Yet 14 of the 17 patients died, giving a mortality of 82 per cent. Combining the two series of cases, the mortality of agranulocytic angina treated with liver is found to be 62 per cent.

From these figures, it may be concluded that the 7 recoveries in the 9 cases treated with liver extract alone were due to chance, and that the 62 per cent mortality of the combined series is a more just evaluation of the usefulness of liver extract in agranulocytic angina.

Stimulating doses of x-rays were first introduced as a therapeutic measure in agranulocytic angina by Friedemann and Elkeles,<sup>11</sup> and have been used by many others since that time. There has been much conflict of opinion as to whether large or small doses should be used. Therefore, any therapeutic exposure has been considered to be adequate.

Only 5 cases have been reported in the literature since 1933 that were treated by x-ray alone. Of

these, 4, or 80 per cent, were fatal. The number of cases is too small to be significant. However, 22 other cases have been reported that have received x-ray treatment as well as some other form of therapy. Of these patients 14 died, a mortality of 64 per cent. The mortality for cases treated by x-ray alone and x-ray combined with some other form of therapy is therefore 67 per cent. The figure obtained in a series of 27 cases is probably significant, and the mortality of 67 per cent in this series, shows that x-ray therapy is of little value in the treatment of agranulocytic angina.

Transfusion has been suggested by some as a useful form of treatment. Any amount or number of transfusions have been considered adequate, and the time interval has been arbitrarily taken as seventy-two hours. Seventeen cases have been reported as treated by transfusion alone. Fourteen patients died, a mortality of 82 per cent, which is about the same as that of the untreated cases. Fifty-six cases were treated by transfusions together with some other type of therapy. Twenty-nine of these patients, or 53 per cent, died. The combined figures show that the mortality is 60 per cent.

There would seem to be a large discrepancy between the 82 per cent mortality of those cases receiving transfusions only and the 53 per cent mortality of the cases treated with transfusion together with other forms of therapy. But of these latter 56 cases, 24 also received adequate amounts of Pentnucleotide (N.N.R.) and 16 recovered. As 33 per cent is approximately the mortality of cases adequately treated with Pentnucleotide only,<sup>5</sup> and as the mortality of cases treated with transfusion alone is 82 per cent, it may properly be assumed that the recoveries in these 24 cases were due largely to Pentnucleotide. Therefore, the corrected mortality for cases treated by transfusion should be 74 per cent. The results in the entire series of cases receiving transfusion with or without other forms of therapy exclusive of those treated with Pentnucleotide indicate that transfusions decrease the mortality only 4 per cent. Transfusion, therefore, does not appear to alter materially the number of blood leukocytes or to affect favorably the bone marrow, and cannot be considered a specific remedy for agranulocytic angina.

Giffin and Watkins<sup>17</sup> have suggested that yellow bone marrow might be of value in agranulocytic angina on the theory that it contains a factor that overcomes the maturation arrest of the leukocytes. They recommend 300 to 500 gm of desiccated marrow taken by mouth. Marberg and Wiles<sup>18, 14</sup> have treated patients with extracted bone marrow and report that a reaction may be expected in twenty-four to forty-eight hours. These latter

authors have treated 26 cases with this method, but report only 8 in enough detail to be considered from a statistical point of view. Four of these patients recovered when bone-marrow extract only was used, and 3 when the extract was used with some other form of therapy. In the remaining case, bone-marrow extract was given when the patient had obviously started to recover and after Pentnucleotide had been administered in full doses on each of the preceding four days. Three other cases have been reported that received adequate bone marrow along with other forms of therapy. Of these, 1 patient died. Thus the mortality of all cases treated with yellow bone-marrow extract is 10 per cent. Giffin and Watkins<sup>15</sup> have recently reported a series of 24 cases that received bone-marrow extract only. The results in the series were excellent, but unfortunately the cases were not presented in sufficient detail to be included in the present analysis.

It is impossible to draw any definite conclusions from such a small series, but the apparent success of this method of therapy should stimulate its further use and study. It is to be noted, however, that because of the frequent presence of necrotic lesions and edema in and about the mouth in cases of agranulocytic angina, swallowing is often difficult or even impossible, therefore, any method of therapy that depends on oral administration may be limited.

"Leukocytic cream" injections have been advocated by Strumia<sup>16</sup> as a means of specific therapy. The dose recommended by the author is the "cream" from 100 to 150 cc of whole normal human blood, injected intramuscularly daily. According to Strumia, a favorable response should be expected in from one to three days. He reports 5 cases treated by this method alone with 100 per cent recovery. One case has been reported where the treatment failed. Six additional cases have been reported where leukocytic cream was used with some other means of therapy. Of these patients, only 1 died. There is thus a combined mortality of 17 per cent. From such a small series one cannot draw any valid conclusions, yet the success in these cases warrants further study of this method of treatment.

Adenine sulfate was first advocated as a substance that might be specific in agranulocytic angina by Reznikoff<sup>17</sup> in 1930. At that time the dose recommended was 0.5 gm, injected intravenously twice daily. In 1933, Reznikoff<sup>13</sup> reported the results of 15 cases and set the standards for this method of treatment. The dosage then recommended was 1 gm, given intramuscularly three times a day, and recovery was expected to start in twenty-four to forty-eight hours. In the 15

mental disorder associated with chronic leukopenia

Seventy-five of the remaining 390 cases received no treatment aimed specifically at the bone-marrow dyscrasia. Death occurred in 78 per cent of these, a mortality rate essentially the same as that given by other authors.<sup>6, 7</sup> It may therefore be concluded, with some degree of assurance, that the mortality when no specific treatment is given is in the vicinity of 75 or 80 per cent.

In order to determine the value of a specific method of therapy, the agent must be given in adequate amounts and sufficient time must be allowed for it to act. If inadequate amounts are administered, or if adequate amounts have been given but the patient succumbs before beneficial action could result, the case must be considered as inadequately treated. The following types of cases must be placed in this class:

(1) Those in which the patients died before the treatment could have had time to influence the bone marrow to renewed activity, as evidenced by the rise of white cells in the peripheral blood. This time interval varies with the particular type of therapy used and will be discussed later.

(2) Those in which the patients recovered or showed unquestionable hematologic response to therapy in a similar time interval.

(3) Those in which the patients died without receiving adequate amounts of a given therapeutic agent, no matter how long they may have been hospitalized.

(4) Those in which the patients recovered under similar circumstances.

It would be expected that the mortality of these inadequately treated cases would be approximately the same as that of a series that had received no specific therapy whatever. This proves to be the case. Of the 130 cases, death occurred in 95, or 73 per cent.

The parenteral use of liver extract was first suggested by Foran, Sheaff and Trimmer.<sup>8</sup> They used a commercial preparation of the "fraction G" of Cohn, and injected the material derived from 100 gm of liver into the vein or muscle every eight hours until a definite rise in the granulocytes or marked clinical improvement occurred. This dose has been accepted as the minimum requirement. Murphy<sup>9</sup> noted that "there was a prompt and often striking response in the number of white blood cells within a few hours of the beginning of treatment." Others have observed this phenomenon, but Witts, Willcox and Warner<sup>10</sup> point out that there is a definite fall in the leukocyte count in about eighteen hours, and conclude that liver produces a shock-like reaction suggesting peripheral mobilization of preformed cells rather than a stimulation of their production. It has also been claimed that the rise in white-cell

count in pernicious anemia following parenteral liver therapy indicates a stimulating action on the leukocytes, but the relative leukopenia of pernicious anemia is essentially a myelophthisic one, and the slow rise of the white-cell count in this disease under liver therapy is due largely, if not entirely, to the maturation of the immature red cells and the consequent return of the bone marrow architecture to a normal state, thus permitting the unhampered multiplication of leukocytes.

The advocates of liver therapy have set no definite time for the appearance of a favorable response after treatment, but seventy-two hours has been taken as an arbitrary standard, any recovery before this time is regarded as spontaneous, and any death is attributed to inadequate therapy.

Nine cases have been reported in which adequate amounts of liver extract were the only specific therapy used. Eight other cases in which liver extract only was used must be eliminated because of inadequate treatment or because the data presented were insufficient for purposes of analysis. In the 9 adequately treated cases, 7 patients recovered and 2 died, a mortality of 18 per cent.

It would seem from the above figures that liver therapy was definitely successful in the treatment of agranulocytic angina. However, there are 17 other cases reported in the literature in which adequate amounts of liver extract were used together with some other specific method of treatment. If liver were as successful in its effect as the results of the first 9 cases suggest, a similar success would be expected in these 17 cases, since there is no reason to believe that any of the other measures used would interfere with any possible beneficial action of the liver. Yet 14 of the 17 patients died, giving a mortality of 82 per cent. Combining the two series of cases, the mortality of agranulocytic angina treated with liver is found to be 62 per cent.

From these figures, it may be concluded that the 7 recoveries in the 9 cases treated with liver extract alone were due to chance, and that the 62 per cent mortality of the combined series is a more just evaluation of the usefulness of liver extract in agranulocytic angina.

Stimulating doses of x-rays were first introduced as a therapeutic measure in agranulocytic angina by Friedemann and Elkeles,<sup>11</sup> and have been used by many others since that time. There has been much conflict of opinion as to whether large or small doses should be used. Therefore, any therapeutic exposure has been considered to be adequate.

Only 5 cases have been reported in the literature since 1933 that were treated by x-ray alone. Of

these, 4, or 80 per cent, were fatal. The number of cases is too small to be significant. However, 22 other cases have been reported that have received x-ray treatment as well as some other form of therapy. Of these patients 14 died, a mortality of 64 per cent. The mortality for cases treated by x-ray alone and x-ray combined with some other form of therapy is therefore 67 per cent. The figure obtained in a series of 27 cases is probably significant, and the mortality of 67 per cent in this series, shows that x-ray therapy is of little value in the treatment of agranulocytic angina.

Transfusion has been suggested by some as a useful form of treatment. Any amount or number of transfusions have been considered adequate, and the time interval has been arbitrarily taken as seventy-two hours. Seventeen cases have been reported as treated by transfusion alone. Fourteen patients died, a mortality of 82 per cent, which is about the same as that of the untreated cases. Fifty-six cases were treated by transfusions together with some other type of therapy. Twenty-nine of these patients, or 53 per cent, died. The combined figures show that the mortality is 60 per cent.

There would seem to be a large discrepancy between the 82 per cent mortality of those cases receiving transfusions only and the 53 per cent mortality of the cases treated with transfusion together with other forms of therapy. But of these latter 56 cases, 24 also received adequate amounts of Pentnucleotide (N.N.R.) and 16 recovered. As 33 per cent is approximately the mortality of cases adequately treated with Pentnucleotide only,<sup>6</sup> and as the mortality of cases treated with transfusion alone is 82 per cent, it may properly be assumed that the recoveries in these 24 cases were due largely to Pentnucleotide. Therefore, the corrected mortality for cases treated by transfusion should be 74 per cent. The results in the entire series of cases receiving transfusion with or without other forms of therapy exclusive of those treated with Pentnucleotide indicate that transfusions decrease the mortality only 4 per cent. Transfusion, therefore, does not appear to alter materially the number of blood leukocytes or to affect favorably the bone marrow, and cannot be considered a specific remedy for agranulocytic angina.

Giffin and Watkins<sup>12</sup> have suggested that yellow bone marrow might be of value in agranulocytic angina on the theory that it contains a factor that overcomes the maturation arrest of the leukocytes. They recommend 300 to 500 gm of desiccated marrow taken by mouth. Marberg and Wiles<sup>13, 14</sup> have treated patients with extracted bone marrow and report that a reaction may be expected in twenty-four to forty-eight hours. These latter

authors have treated 26 cases with this method, but report only 8 in enough detail to be considered from a statistical point of view. Four of these patients recovered when bone-marrow extract only was used, and 3 when the extract was used with some other form of therapy. In the remaining case, bone-marrow extract was given when the patient had obviously started to recover and after Pentnucleotide had been administered in full doses on each of the preceding four days. Three other cases have been reported that received adequate bone marrow along with other forms of therapy. Of these, 1 patient died. Thus the mortality of all cases treated with yellow bone-marrow extract is 10 per cent. Giffin and Watkins<sup>15</sup> have recently reported a series of 24 cases that received bone-marrow extract only. The results in the series were excellent, but unfortunately the cases were not presented in sufficient detail to be included in the present analysis.

It is impossible to draw any definite conclusions from such a small series, but the apparent success of this method of therapy should stimulate its further use and study. It is to be noted, however, that because of the frequent presence of necrotic lesions and edema in and about the mouth in cases of agranulocytic angina, swallowing is often difficult or even impossible, therefore, any method of therapy that depends on oral administration may be limited.

"Leukocytic cream" injections have been advocated by Strumia<sup>16</sup> as a means of specific therapy. The dose recommended by the author is the "cream" from 100 to 150 cc of whole normal human blood, injected intramuscularly daily. According to Strumia, a favorable response should be expected in from one to three days. He reports 5 cases treated by this method alone with 100 per cent recovery. One case has been reported where the treatment failed. Six additional cases have been reported where leukocytic cream was used with some other means of therapy. Of these patients, only 1 died. There is thus a combined mortality of 17 per cent. From such a small series one cannot draw any valid conclusions, yet the success in these cases warrants further study of this method of treatment.

Adenine sulfate was first advocated as a substance that might be specific in agranulocytic angina by Reznikoff<sup>17</sup> in 1930. At that time the dose recommended was 0.5 gm., injected intravenously twice daily. In 1933, Reznikoff<sup>18</sup> reported the results of 15 cases and set the standards for this method of treatment. The dosage then recommended was 1 gm., given intramuscularly three times a day, and recovery was expected to start in twenty-four to forty-eight hours. In the 15

cases, only 5 patients lived longer than twenty-four hours and all survived. Eight cases must be classified as inadequately treated either because of dosage or the time element. One patient recovered after adequate amounts of adenine sulfate together with other supposedly specific therapeutic agents. One recovered with transfusion and inadequate amounts of adenine sulfate. One other case has been reported that was cured by using adenine sulfate alone. Three further cases are on record that received this drug along with other therapeutic agents. Two of these patients died. The mortality of all these 10 cases treated with adequate amounts of adenine sulfate with or without other presumably specific agents is therefore 20 per cent.

Although the series is small, the 20 per cent mortality indicates that adenine sulfate should be given a more extensive trial in the future. It should be noted that this drug is one of the essential degradation products of Pentnucleotide.

Pentnucleotide was first suggested as a form of therapy by Jackson et al.<sup>19</sup> in 1931. In 1924 one of us<sup>20</sup> showed that normal human blood contained appreciable quantities of nucleotide, and later Doan<sup>21</sup> demonstrated that intravenous injections of this substance raised the peripheral white-cell count in normal rabbits. Pentnucleotide may be given intramuscularly or intravenously. In agranulocytic angina, 10 cc of Pentnucleotide is given intramuscularly four times a day until the white-cell count has definitely risen and young neutrophils have appeared. In favorable cases, this change usually occurs from the third to the sixth day after the initiation of treatment. Ten cubic centimeters is then given once or twice a day until the white-cell count has been normal for several days. If there has been no response at the end of ten days, further therapy with Pentnucleotide is probably useless.<sup>5</sup> All cases which terminated fatally within forty-eight hours or which showed signs of recovery within seventy-two hours were considered as inadequately treated, and 20 cc a day was taken as the minimum dose simply because this smaller dose was originally recommended by Jackson. None of the cases previously reported by Jackson and Parker<sup>5</sup> are included in the present analysis.

Forty-one cases of agranulocytic angina have been reported since 1933 that have been treated by Pentnucleotide only. Of these patients 12, or 29 per cent, died. Forty-four patients have been reported treated with adequate amounts of Pentnucleotide as well as some other form of therapy. Of these 18, or 40 per cent, died. The total mortality of the two groups of 85 cases is 35 per cent.

The 35 per cent mortality for these 85 cases recorded in the literature is essentially the same as

Jackson and Parker's<sup>5</sup> mortality rate of 33 per cent reported in 1935 from a series of 103 cases.

The question may be raised as to whether it is proper to compare the mortality of patients treated with some specific therapy for at least seventy-two hours with that of patients who have not re-

*Mortality Rates Following Various Types of Treatment in 390 Cases of Acute Agranulocytic Angina*

TREATMENT	NO OF CASES	PERCENTAGE MORTALITY
Untreated	75	38
Inadequately treated	130	73

With other therapy	4	50
Pentnucleotide	85	35
Alone	41	29
With other therapy	44	40

ceived any specific therapy (untreated cases) and who in some cases have not lived long enough to receive the theoretical benefits of seventy-two hours of general hospital care. The mortality of those cases which did not receive specific therapy but which were hospitalized and given general care for more than three days has therefore been determined. Of the 43 patients in this group, 30 or 70 per cent, died. This figure is but slightly lower than that for the untreated cases. It would therefore appear that a notable reduction in the mortality rate by any presumably specific agent given over a period of seventy-two hours could properly be attributed to the therapy.

#### SUMMARY AND CONCLUSIONS

Three hundred and ninety cases recorded in the literature since 1933 as agranulocytic angina have been analyzed in order to evaluate so far as possible the efficacy of the various therapeutic agents advocated as specific or helpful.

The mortality in 75 untreated cases was found to be 78 per cent.

The mortality in 43 cases which received no specific therapy but which received more than three days of general hospital care was 70 per cent.

The mortality in the 130 cases receiving inadequate amounts of any supposedly specific therapy was 77 per cent.

Neither transfusions nor x-ray therapy seemed to alter the mortality rate

Treatment by yellow bone-marrow extract, leukocytic cream or adenine sulfate has not been widely enough reported upon to permit any accurate conclusions as to their worth. Because of the low mortality in the cases so far reported, these measures deserve further trial.

The mortality in the 26 cases treated with adequate amounts of liver extract was 62 per cent.

The mortality in the 85 cases treated with Pentnucleotide was 35 per cent, a figure closely approximating that reported by Jackson and Parker<sup>5</sup> in 1935. None of the latter cases are included in the present analysis.

At present, it would appear that Pentnucleotide in doses of at least 40 cc a day is the most promising form of specific therapy in this disease.

## A CONSTRUCTIVE PROGRAM OF MEDICAL CARE FOR THE LOW-INCOME GROUP\*

CHANNING FROTHINGHAM, M.D.†

BOSTON

ANY program for the medical care of the low-income group does not apply to the care of the indigent which is generally conceded to belong to government, either local, state or federal. Unfortunately the dividing line between the indigent and low-income groups is an exceedingly difficult one to draw, and the fact that it is drawn at different levels in different communities adds to the confusion.

The evidence is conclusive that medical care must be expensive for certain illnesses if it is to be good. Some provision, therefore, must be made for individuals in the low-income group to meet this cost, because all groups in our population must receive good medical care. Without trying to define just what the limits of income are for this group, it is fair to say that a very large number, probably more than half of our population, fall within it. Governmental compulsory health insurance has been suggested by the politicians

as the means to provide good medical care for this large low-income group. Although compulsory health insurance as developed in some instances, such as the system adopted by the Southern Pacific Railroad, results in satisfactory medical service, there are grave doubts in the minds of most of the members of the medical profession in regard to the quality of medical care under such a system when provided by the government. These doubts are based on the experiences in other countries where, although the people say they are satisfied with the care they receive under what amounts to compulsory health insurance, the evidence suggests that the type of medical service offered is far from ideal. Furthermore, the experience has been that under governmental compulsory insurance plans it has been difficult for the individual to remain the private patient of his family physician, and it is generally conceded that better medical service results if patients have one chief medical adviser or family physician who is familiar with the environment of the patient and who knows something of the patient's background. In addition

Presented in part at a New England Town Meeting on the Air (Subject: What Can the Medical Profession Offer in Place of Compulsory Health Insurance?) Boston February 21 1939.  
†President Massachusetts Medical Society.

tion to the possibility of deterioration in medical service under a governmental compulsory health insurance plan, it is evident that such a plan suddenly applied to this country would create a tremendous overhead expense which might well be avoided if the government only took over its share of the financial burden for the care of the low-income group as the need for it became evident along evolutionary lines.

Many physicians believe that a constructive program can be worked out on a community basis so that the individual in the low-income group in any community may remain the private patient of his own physician without undue financial burden. The size of the individual community in which such a plan may be developed will naturally vary with the density of the population, the topography of the country and the means of transportation. The object of the plan is to spread throughout the community the cost of the medical care for the few unfortunate ones who have the types of illness that are expensive. In some communities, part of this cost can be borne by private philanthropy, as is done at the present time. Although large fortunes seem to be diminishing throughout the country, the endowment already involved in medical care will undoubtedly persist, and the ability to raise money for community chests suggests that additional funds from private sources will continue to be donated for this purpose for some years to come. However, private philanthropy will not be able to carry the entire load, and other means must therefore be developed to pay for the medical care of the individuals in the low-income group who need it. Some type of insurance against the expense of illness or financial assistance from public funds raised by taxation seems to be the most logical way to make up any deficiency after the resources of private philanthropy are exhausted.

With the development of the following three-point program in each community the individuals in the low-income group should be able to receive the best of medical care at a cost within their means. The program consists in (1) a community hospital, (2) a non-profit insurance plan for the payment of hospital bills, and (3) a non-profit insurance plan for the payment of physicians' bills or some type of group or contract practice.

#### COMMUNITY HOSPITALS

As most of the patients who have illness which is costly have to be hospitalized, each community should have a hospital available for all its citizens. In such a hospital there should be proper equipment for practically all diagnostic procedures and treatment. In this way the expense of

elaborate equipment for diagnosis and treatment will be borne by the community as a whole and will be available to all the citizens. In order to make it available to all citizens such a hospital must be opened to all *properly qualified* physicians of the community for the care of their private patients. Not many years ago only charity patients went to hospitals, and in order to avoid confusion in the care of these patients, the professional staffs of hospitals were limited to certain physicians. The result has been that in some communities still there is a tendency to believe that the staff of a hospital should be limited, but even if this is necessary, I believe it should only apply to the care of the charity patients. If a hospital is supported by the community, it is only proper that any member of the community should be allowed to be treated in the hospital by his own physician, provided that the physician is properly qualified. On the other hand, the trustees of such a hospital have responsibility in regard to the work done therein, and definite rules should therefore be established which limit a physician to practice only that type of medicine or surgery for which he is qualified. These community hospitals may be wholly supported by private philanthropy, as mentioned above, or there may be need of aid from the taxes collected in the community. It is also possible that some communities, even with the aid of local taxes, may not be able to support a properly equipped hospital, in which case the community would have to appeal to the public funds of the state, and if the latter were not able to support a sufficient number of community hospitals to serve its population it would be necessary to appeal to the federal government for aid. If it were necessary to appeal to the federal government for funds for any community it would be much more economical for the government to respond to such appeals individually than for it to set up an elaborate bureau to provide funds in general for the support of community hospitals.

#### INSURANCE FOR HOSPITAL BILLS

The second point in the program consists in the development of voluntary non-profit insurance plans to provide for the payment of hospital bills. The average cost throughout the country for this type of insurance, which usually covers three weeks of hospitalization, is about ten dollars a year for semi-private accommodations, and now an even cheaper rate is being developed for ward service. Such plans have developed on a tremendous scale in recent years, and the evidence shows that no non-profit voluntary plan organized on sound actuarial lines has failed since this movement started. Unfortunately, along with these suc-

insurance plans, others based on less sound lines have sprung up which have not been successful, and which have threatened bringing this type of insurance into disrepute among careless thinkers. An example of the debt the public for such plans is the growth of the Associated Hospital Service Corporation of Massachusetts, popularly known as the Blue Cross Corporation started out to insure only groups of employed people. The first policy was sold in 1937, and it was hoped that by the end of the year there might be 20,000 subscribers. At the end of the year and six months there were over 160,000 subscribers! Already this type of insurance has been made available to more people than were originally planned for, and it is hoped that as it goes on this type of insurance will be available for all the people.

#### INSURANCE FOR PHYSICIANS' BILLS

A third point in the program consists in the development of various non-profit plans of insurance or contract nature to pay the physician's bill, so that the individual may remain the patient of his family physician and meet the expense of specialism when necessary. There are many such plans in operation throughout the country, but not as yet many of a voluntary non-profit variety, the latter is in part due to the difficulty in securing proper statistics upon which to base actuarial tables. Another serious difficulty in the development of such plans has been the conservatism on the part of the medical profession in approving specific insurance plans proposed by interested individuals, especially if these suggest group or contract practice. There seems to be a fear on the part of organized medicine that contracts will lead to deterioration in medical service. The unpleasantness in the District of Columbia, which has resulted in the federal government suing organized medicine, apparently originated in the hostility of organized medicine to a contract arrangement for the payment of doctors' care for a group of individuals. That some type of contract or group medicine may lead to better medical service must be admitted, but organized medicine must realize that, in some instances, medical care may actually be better on a contract basis. The medical officers in the United States Army and the United States Public Health Service are on a contract basis, and the work of these physicians needs no criticism. Many industrial firms take excellent care of their employees employing physicians on a contract basis, and many American colleges have contract physicians to care for their students with results far superior to those of former times. The actual facts

are that some work may be done better on a contract basis and that in other instances the stimulation of the fee system produces better results. There is room for both methods of paying for medical service in this large country of ours.

In a discussion of any insurance or contract plan for paying physicians' bills one almost always hears the question, Does this permit the free choice of physician? Just when and how this expression arose in discussion of economic problems in medicine it is hard to say, but it probably originated with the development of compulsory insurance acts, such as those which cover industrial and automobile accidents in this country or of governmental insurance plans in other countries. With the former the private insurance companies involved in this work often tried to have the patients cared for only by the company doctors. The medical profession quite properly objected to this and succeeded in making it possible for an individual treated under these compulsory forms of insurance to have the physician of his choice. The threat that "free choice of physician" is eliminated in voluntary insurance and voluntary contract plans for the payment of physicians' bills is frequently used by objectors to these plans, but I insist improperly so. For if an individual voluntarily joins a plan for medical service in which it is known who the physicians are, it would seem that the individual is choosing those physicians just as freely as he chooses his physicians when he goes to one of the large private clinics of this country, of which there are many. Therefore, the medical profession should not let this expression "free choice of physician" interfere with the development of plans for distributing the cost properly created by physicians' bills.

Just what the cost will be per individual for insurance against appropriate physicians' bills for this class of patients cannot yet be as accurately judged as the cost of insurance against hospital bills, but enough plans have been tried to make it evident that it can be obtained at a figure within the reach of the low-income group.

If this three-point program is developed, there will be available for all the people of the country properly equipped hospitals which will provide aids for diagnosis and treatment which are too expensive for individual physicians or groups of physicians to maintain. The expense of these hospitals will be borne by the community as a whole, with the funds collected as mentioned above. Some of the support of these hospitals will be provided by the charges to patients who enter the hospital, but these hospital charges for the individual will be paid by the non-profit in-

insurance companies, so that this cost will not be a severe financial burden on any one individual. Finally the physicians' bills will be paid by some non-profit insurance company or provided for on a contract basis so the individual will not have to meet any unusually high cost. By this program, therefore, the individual in the low-income group can remain the private patient of his own

physician for the great majority of illnesses. Let us hope that by the development of such programs the individuals in the low-income group will be satisfied with their medical care, so that complaints from this large percentage of the population will not stimulate the politicians into governmental action aimed toward the establishment of compulsory health insurance.

## THE ASSAY OF CRYSTALLINE AND URINARY ANDROGENS\*

With Special Reference to Their Measurement by a Colorimetric Method

HARRY B. FRIEDGOOD, M.D.,† AND HELEN L. WHIDDEN, M.A.

BOSTON

RECENT advances in the physiology and biochemistry of the secretions of endocrine glands have made it possible to begin a study of certain phases of the complex problem of hirsutism in women. The importance of discovering the etiologic factors responsible for this condition and the measures necessary for its alleviation can be judged only in terms of the disfiguring nature of the affliction, the serious emotional disturbances which it initiates and the clinical disorders with which it is commonly associated.

The most recent advances in the study of hirsutism and virilism are being made along biochemical lines. Because of the obvious association between the biologic activity of male sex hormones and the physical characteristics of hirsutism and virilism, attention has been directed in such patients to the extraction and quantitative determination of urinary and blood constituents possessing the biological action of male hormones. Before studies of this type were undertaken, it had been determined that androgens are excreted normally in the urine of both men and women.<sup>1-3</sup> The total androgenic activity of normal male urine was found to be somewhat higher than that of normal female urine, although in many cases there was no obvious quantitative distinction.<sup>1-3</sup> The chemical nature of the androgens in normal female urine is still unknown except for traces of dehydroisoandrosterone (Callow<sup>4</sup>). In the urine of normal men the biological activity was traced in part to androsterone and dehydroisoandrosterone, which are present in approximately equal amounts.<sup>4-6</sup> Epi-etiocholanediol, a biologically inactive androgenic substance,<sup>7</sup> has also been isolated from the

urine of normal men. Since these do not account for the entire androgenic activity of normal male urine, there must be other androgens which still remain to be identified.

Chemical methods for the extraction of urinary androgens have been perfected to a more satisfactory degree than have those for the recovery of androgens circulating in the blood.<sup>8</sup> The former method, therefore, has been used almost exclusively in the expectation that the level of excretion in the urine of substances with male sex hormone activity might give some indication of the nature of the pathologic physiology of the endocrine glands in hirsutism and virilism. However, quantitative determination of the biological activity of substances excreted in the urine is at present an unreliable method for estimating hormonal activity in the body. Justification for the use of such urinary assays as an index of the physiologic activity of certain endocrine glands necessitates assumptions for the support of which there is no reliable evidence at present. One must assume, for instance, that the total biological activity of the urinary androgens is either equal to or quantitatively proportional to the biological activity of the tissue androgens. As a matter of fact, the androgens which have been identified in urine are not identical in chemical structure with those extracted from endocrine tissues, although they are similar to them. Adrenosterone<sup>9</sup> and testosterone<sup>10</sup> have been extracted only from endocrine tissues, the former from adrenal cortex, the latter from testis. Androsterone,<sup>11</sup> dehydroisoandrosterone<sup>12</sup> and epi-etiocholanediol,<sup>7</sup> on the other hand, have been recovered only from urine extracts. It is not known precisely how these two groups of androgens are related physiologically to each other. Even were this relation well established, the bioassay of urinary androgens, as employed at present, could at best give only a crude idea of the

physiology of the male sex hormones, because such assays reveal merely the *total* biologic activity of a mixture of androgenic substances. The composition of this mixture is only partially known, only three of the androgens having been identified chemically in the urine of men, and no two of them possessing the same order of activity.<sup>12</sup> The relative proportions in which urinary androgens are excreted are thus escaping attention and may have an important bearing on the normal and pathologic physiology of the tissue androgens.

The problem is complicated still further by the fact that less than 5 per cent of androgens administered by injection can be detected in the urine by bioassay.<sup>4, 13, 14</sup> Is this due to the method of their extraction which as yet is not fully developed, or is the hormone so altered during its activity in the body and its preparation for excretion that it becomes unrecognizable even as a degradation product in the urine? It is known, of course, that sex hormones may be secreted in one form (for example progesterone) and excreted in another (sodium pregnanediol glycuronide).<sup>15</sup> This possibility must be taken into consideration, therefore, in connection with the apparent discrepancy between the intake and output of androgenic substances.

As might be expected from this survey of the problem, the results of urinary bioassays in hirsutism and virilism have added but little to our understanding of these conditions except in those patients whose virilism is due to an adrenocortical tumor. The total urinary androgens in hirsutism or virilism (not due to adrenal tumors) are either within normal limits or only moderately elevated.<sup>4, 16, 17</sup> The total urinary androgens in patients with virilism due to adrenocortical tumors, however, are unusually high and, therefore, of distinct diagnostic importance.<sup>4, 18</sup> In 1 such case Callow traced 70 per cent of this androgenic activity to dehydroisoandrosterone.<sup>19</sup> In cases of adrenal hyperplasia, Butler and Marrian isolated isoandrosterone and pregnane-3,17,20-triol from the urine.<sup>20, 21</sup> This may be significant because these androgens have not been found in the urine of normal people. In spite of the difficulties which have been pointed out, it is studies such as these, in addition to those of normal people which necessarily preceded them, which have given us a point of departure from which to extend further investigations more advantageously.

Aside from the fact that at present one cannot make use of the urinary androgens as an index to the biological activity of the tissue hormones, the usefulness of this method is impaired still further by other considerations. The results obtained by bioassay, as it is now being practiced, are de-

pendent in large measure on variables which significantly affect their quantitative accuracy and which at present are not strictly controllable. In support of this contention one may cite the following:

(1) The capon method of bioassay has no sharply defined end point, because a capon unit is ordinarily defined in terms of an average increase in comb growth in a limited number of caponized birds. Because of inherent biological differences, particularly in capons not belonging to a highly inbred strain, the dosage response relation varies considerably in individual animals. As the number of animals used in a test is limited, only three to five birds being employed for most assays, there is a distinct possibility of introducing significant errors in such determinations. Recognizing this difficulty, Koch<sup>12</sup> advocates the use of more capons per test.

(2) The results of capon assays vary considerably even if the technic is fundamentally the same. In the hands of various investigators the capon unit has been assigned values ranging from 100 to 200% crystalline androsterone.<sup>22-28</sup> Moreover, if the method of hormone administration is changed from intramuscular injections to the application of androgens directly to the capons' comb by inunction, the biological effect of the androgen may be enhanced by more than fifty times.<sup>27-30</sup>

(3) Furthermore, the order of activity of various androgens likewise depends on their method of administration. With the intramuscular technic testosterone is six times as active and dehydroisoandrosterone one third as active as androsterone,<sup>12</sup> but testosterone and androsterone are similar in activity when given by inunction.<sup>28</sup>

(4) The nature of the solvent in which the hormone is administered may alter radically the biological effect of a given androgen. In the comb-growth method and in the castrate rat assay the use of alcohol as a solvent for androsterone enhances its activity twofold as compared with oil.<sup>28, 31</sup>

(5) Finally, if the castrated rat is used for bioassay, the presence of certain substances, some of which are unknown, greatly increases the androgenic activity of hormones or hormone-like chemical substances. David and Freud and their collaborators<sup>32, 33</sup> have isolated from the testis what they have termed an X substance which greatly activates androgens such as testosterone, when the latter is tested on the accessory sex organs of the castrated rat. It has been demonstrated also that certain of the higher fatty acids, notably palmitic acid, possess this property of activating androgens.<sup>34</sup>

One may conclude from this brief critique that the bioassay of the *total* androgen content of urine has only a limited usefulness in clinical medicine. So far as is now known, the total urinary androgen is elevated significantly only in cases of virilism due to adrenal tumor. The results of bioassay may be more significant when all the urinary androgens are isolated and identified, and the nature of their physiologic and biochemical relation to the tissue androgens is established. No one knows as yet whether the relative proportions in which various urinary androgens are excreted are significant in health and disease. For clinical purposes, there-

insurance companies, so that this cost will not be a severe financial burden on any one individual. Finally the physicians' bills will be paid by some non-profit insurance company or provided for on a contract basis so the individual will not have to meet any unusually high cost. By this program, therefore, the individual in the low-income group can remain the private patient of his own

physician for the great majority of illnesses. Let us hope that by the development of such programs the individuals in the low-income group will be satisfied with their medical care, so that complaints from this large percentage of the population will not stimulate the politicians into governmental action aimed toward the establishment of compulsory health insurance.

as acetoacetic acid, creatinine, estrogens and other phenols which might have a ketonic group, and which would therefore interfere with the accuracy of the results obtained by the chemical procedure

Our patients were studied for from two to eight weeks, their urines were collected in twenty-four amounts three times a week and prepared for assay within twenty-four to forty-eight hours after collection. We have reported the results of assays in color units read directly from the instrument and have stated their equivalents in crystalline androsterone. The amount of the ketonic sterols in the neutral fraction of the urinary extracts can be estimated, therefore, in terms of crystalline androsterone. In this way the results of chemical assay are made comparable with those obtained by bioassay

Although the detailed results of our clinical studies are being reported elsewhere, we wish to indicate here to what extent our chemical method of assay has been applied to the practical problems of clinical endocrinology. Extensive observations have been made on 3 normal women, 21 individuals with hirsutism and 2 patients with virilism due to adrenocortical tumors. The urines of the normal women were assayed three times a week for four weeks, those of the patients with hirsutism three times a week for four to eight weeks. The patients with adrenal tumors were studied at similar intervals for one month and twelve months, respectively. Normal young women excreted the equivalent of 4 to 15 mg of androsterone per twenty-four hours. As the series grows larger, we expect that the lower limit will decrease, the upper limit probably will not change appreciably. Patients with hirsutism excreted the equivalent of 1 to 29 mg of androsterone per twenty-four hours. Most of the results in this group fell within the normal range, relatively few excreted the equivalent of over 20 mg of androsterone per twenty-four hours. There seemed to be no fixed relation between the extent of hirsutism and the total androgen excretion. Mild cases of hirsutism do not ordinarily excrete large amounts of androgen, and extensive cases also may excrete relatively small quantities. The most remarkable excretion of androgens is encountered in patients with virilism resulting from adrenocortical tumors. In 2 such cases<sup>11</sup> we found the androgen excretion to be the equivalent of 45 and 325 mg of androsterone per twenty-four hours at various stages of the disease. The highest values appeared when the malignancy metastasized.

Callow, Callow and Emmens<sup>10</sup> have demonstrated that there is a statistically significant correlation between the results of bioassay and those

derived from the chemical test. Although Callow and her colleagues have employed a modification of Zimmermann's reaction which differs from ours, the results from both laboratories are essentially the same.<sup>10</sup> In their series normal women excreted <2.2 to 9.9 mg sterone per day, hirsute patients excreted <2.2 to 33 mg and patients with adrenal tumors excreted 150 to 175 mg. Their phrase "milligrams sterone" refers to the amount of color-producing ketonic substances in the urine and represents the chromogenic equivalent of crystalline androsterone.

Callow's studies and ours are also in substantial agreement on other points in the colorimetric assay of urinary androgens

(1) As measured colorimetrically, the androgen excretion of normal and hirsute patients may vary considerably from day to day just as has been reported for the bioassay

(2) The colorimetric determination of urinary androgens yields higher values than can be obtained by bioassay. This is not at all surprising, for several reasons. In the first place, urine probably contains biologically inactive ketonic sterols, which are chemically closely related to androsterone and dehydroisoandrosterone and behave similarly from a chemical viewpoint. In the second place, there may be non-androgenic substances in the urine, as yet unknown, which react like androsterone with metadinitrobenzene. If present at all, they are there in only relatively small quantities, judging from the results obtained from bioassay and colorimetric assay

#### DISCUSSION

The chemical (colorimetric) method gives consistent results, and there is a significant correlation between these results and those obtained by bioassay. Because it incurs less expense and is less time-consuming the chemical method is probably superior for clinical use to that of bioassay. It is apparent from our own data and that of Callow's that the chemical method can be used more advantageously in the diagnosis of adrenocortical tumors in patients with virilism. We are in agreement with reports in the literature that there is an excessive daily excretion of androgen in cases where an adrenocortical tumor exists, and Callow has found that 70 per cent of this androgenic activity can be accounted for by dehydroisoandrosterone. The remarkably high values for urinary androgens thus far seem to constitute an important differential point between the benign type of hirsutism and that caused by a neoplasm. It remains for further investigation to determine whether these strikingly elevated values for the urinary androgens are specifically characteristic

fore, it is advisable to substitute for the bioassay a less laborious and less expensive technic, which necessitates no greater assumptions than are already being made with the method of bioassay. Such a technic became possible following the establishment of the chemical structure of certain of the androgens and closely related steroids. This method of assay is based on a colorimetric reaction, which was applied to the quantitative estimation of crystalline and urinary androgens. We have proved to our own satisfaction that by means of it one may assay quantitatively crystalline androsterone and dehydroisoandrosterone, and that it is adaptable to the assay of urinary androgens.

The colorimetric method of assaying androgens was first described by Zimmermann<sup>35, 36</sup>. It was modified later by Wu and Chou,<sup>37</sup> Oesting,<sup>38, 39</sup> and Callow, Callow and Emmens.<sup>40</sup> This method of assay is based essentially upon a nonspecific chemical reaction in which substances containing a  $-CH_2CO$  group react in an alkaline alcoholic solution with metadinitrobenzene to produce characteristic colors. The shade and intensity of these colors depend on a number of variables, such as the temperature of the reaction, the duration of the reaction, the concentration and amount of the alkali, the concentration and amount of the metadinitrobenzene, the relative proportions of alcohol and water, and illumination.

Although Oesting<sup>38, 39</sup> develops his colors at room temperature, we have found, as have all other investigators,<sup>36, 37, 40</sup> that it is necessary to control all these factors rigidly. By modifying certain of the aforementioned variables, we increased the sensitivity of the reaction tenfold as compared with Oesting's modification, and succeeded in eliminating the development of interfering browns which affect the accuracy of the colorimetric determinations.

The procedure for color development according to our modification of the Zimmermann reaction for use in the Oesting colorimeter was applied to the assay of crystalline androsterone and dehydroisoandrosterone in the following manner:

Aliquot portions of an alcoholic hormone solution of known concentration are measured accurately into Oesting's colorimeter tubes, using a previously calibrated 1-cc pipette graduated in 0.01 cc. The alcohol is evaporated off carefully over a water bath at 70-75°C., and after cooling the tubes to room temperature, 0.15 cc. of 95 per cent ethyl alcohol, 0.2 cc. of 2 per cent metadinitrobenzene in absolute ethyl alcohol and 0.2 cc. of 15 per cent aqueous potassium hydroxide are added to each tube. Their contents are then mixed thoroughly. At the same time a control tube containing identical amounts of the two reagents and alcohol is prepared. The tubes are placed in the dark in a water bath maintained at precisely 25°C. and, with occasional shaking, are kept there for one and a quarter hours. The contents of the tubes are then diluted

to a volume of 7 cc. with 95 per cent ethyl alcohol. After being thoroughly mixed, they are assayed immediately in the Oesting colorimeter, which is set up with the necessary precautions to ensure optimal lighting conditions.

Using our modification of the Zimmermann reaction, we first calibrated Oesting's colorimeter with known quantities of crystalline androsterone and dehydroisoandrosterone. Oesting failed to take this precaution and relied wholly on capon assays of urinary androgens (unknowns) for the development of the color and the standardization of the disks in his colorimeter.<sup>38, 39</sup> As a result of our studies we reached the following conclusions:

(1) The intensity of the pink to-red color which develops is proportional to the amount of hormone present in solution.

(2) The disks of the Oesting colorimeter representing color units below 20 are unreliable for quantitative assays.

(3) When colors are developed by Oesting's method and assayed with his colorimeter, 1 color unit is equivalent to approximately 100  $\gamma$  crystalline androsterone, whereas originally he claimed that a color unit was equivalent to  $10 \pm 2$   $\gamma$  androsterone. According to our method 1 color unit is equivalent to 8.96 to 10.04  $\gamma$  crystalline androsterone, depending on the disk used for a given determination. Calibration of the instrument with crystalline androsterone has resulted in the following values for each of the disks:

DISK MARKING	AVERAGE AMOUNT ANDROSTERONE PER UNIT	ANDROSTERONE EQUIVALENT OF EACH DISK
20 units	8.96 $\gamma$	17.92 $\gamma$
28 units	9.04 $\gamma$	25.31 $\gamma$
34 units	9.84 $\gamma$	33.46 $\gamma$
40 units	10.04 $\gamma$	40.16 $\gamma$
50 units	9.63 $\gamma$	48.15 $\gamma$

(4) Crystalline dehydroisoandrosterone gives a more intense pink color per unit of weight than does crystalline androsterone. Quantitatively, it is less of a complicating factor than already exists in the marked differences which are characteristic of the biological activity of these hormones. Further data on this point are being reported in another communication.

Having calibrated each colored disk of Oesting's colorimeter in terms of  $\mu$ -equivalent crystalline androsterone, we then applied our modification of Zimmermann's reaction to the assay of urinary androgens in normal and hirsute women in order to determine whether one could for purely clinical purposes substitute the chemical method for that of bioassay.

Extraction and purification of the androgenic substances were done by a modification of the method of Gallagher et al.<sup>17</sup> This process effectively separates androgens from substances such

as ketosteroids and creatinine, estrogens and other phenols which might have a ketonic group, and which would therefore interfere with the accuracy of the results obtained by the chemical procedure.

Our patients were studied for from two to eight weeks, their urines were collected in twenty-four amounts three times a week and prepared for assay within twenty-four to forty-eight hours after collection. We have reported the results of assays in color units read directly from the instrument and have stated their equivalents in crystalline androstosterone. The amount of the ketonic steroids in the neutral fraction of the urinary extracts can be estimated, therefore, in terms of crystalline androstosterone. In this way the results of chemical assay are made comparable with those obtained by bioassay.

Although the detailed results of our clinical studies are being reported elsewhere, we wish to indicate here to what extent our chemical method of assay has been applied to the practical problems of clinical endocrinology. Extensive observations have been made on 3 normal women, 11 individuals with hirsutism and 2 patients with virilism due to adrenocortical tumors. The urines of the normal women were assayed three times a week for four weeks; those of the patients with hirsutism three times a week for four to eight weeks. The patients with adrenal tumors were studied at similar intervals for one month and twelve months, respectively. Normal young women excreted the equivalent of 4 to 15 mg. of androstosterone per twenty-four hours. As the series grows larger, we expect that the lower limit will decrease, the upper limit probably will not change appreciably. Patients with hirsutism excreted the equivalent of 1 to 29 mg. of androstosterone per twenty-four hours. Most of the results in this group fell within the normal range, relatively few excreted the equivalent of over 20 mg. of androstosterone per twenty-four hours. There seemed to be no fixed relation between the extent of hirsutism and the total androgen excretion. Mild cases of hirsutism do not necessarily excrete large amounts of androgen, and extensive cases also may excrete relatively small quantities. The most remarkable excretion of androgens was encountered in patients with virilism resulting from adrenocortical tumors. In 2 such cases<sup>4</sup> we found the androgen excretion to be the equivalent of 35 and 55 mg. of androstosterone per twenty-four hours at various stages of the disease. The highest values appeared when the malignant metastasized.

Callow and Emmens<sup>41</sup> have demonstrated that there is a statistically significant correlation between the results of bioassay and those

derived from the chemical test. Although Callow and her colleagues have employed a modification of Zimmermann's reaction which differs from ours, the results from both laboratories are essentially the same.<sup>41</sup> In their series normal women excreted <22 to 99 mg. sterone per day, hirsute patients excreted <22 to 33 mg., and patients with adrenal tumors excreted 150 to 175 mg. Their phrase "milligramms sterone" refers to the amount of color-producing ketonic substances in the urine and represents the chromogenic equivalent of crystalline androstosterone.

Callow's studies and ours are also in substantial agreement on other points in the colorimetric assay of urinary androgens:

(1) As measured colorimetrically, the androgen excretion of normal and hirsute patients may vary considerably from day to day just as has been reported for the bioassay.

(2) The colorimetric determination of urinary androgens yields higher values than can be obtained by bioassay. This is not at all surprising, for several reasons. In the first place, urine probably contains biologically inactive ketonic steroids which are chemically closely related to androstosterone and dehydroandrostosterone and behave similarly from a chemical viewpoint. In the second place, there may be non-androgenic substances in the urine, as yet unknown, which react like androstosterone with mercuricacetate. If present at all, they are there in only relatively small quantities, judging from the results obtained from bioassay and colorimetric assay.

#### DISCUSSION

The chemical (colorimetric) method gives consistent results, and there is a significant correlation between these results and those obtained by bioassay. Because it incurs less expense and is less time-consuming the chemical method is probably superior for clinical use to that of bioassay. It is apparent from our own data and that of Callow's that the chemical method can be used more advantageously in the diagnosis of adrenocortical tumors in patients with virilism. We are in agreement with reports in the literature that there is an excessive daily excretion of androgen in cases where an adrenocortical tumor exists, and Callow has found that 70 per cent of this androgenic activity can be accounted for by dehydroandrostosterone. The remarkably high values for urinary androgens thus far seem to constitute an important differential point between the benign type of hirsutism and that caused by a neoplasm. It remains for further investigation to determine whether these striking, elevated values for the urinary androgens are specifically characteristic

fore, it is advisable to substitute for the bioassay a less laborious and less expensive technic, which necessitates no greater assumptions than are already being made with the method of bioassay. Such a technic became possible following the establishment of the chemical structure of certain of the androgens and closely related steroids. This method of assay is based on a colorimetric reaction, which was applied to the quantitative estimation of crystalline and urinary androgens. We have proved to our own satisfaction that by means of it one may assay quantitatively crystalline androsterone and dehydroisoandrosterone, and that it is adaptable to the assay of urinary androgens.

The colorimetric method of assaying androgens was first described by Zimmermann<sup>35, 36</sup>. It was modified later by Wu and Chou,<sup>37</sup> Oesting,<sup>38, 39</sup> and Callow, Callow and Emmens.<sup>40</sup> This method of assay is based essentially upon a nonspecific chemical reaction in which substances containing a  $-\text{CH}_2\text{CO}$  group react in an alkaline alcoholic solution with metadinitrobenzene to produce characteristic colors. The shade and intensity of these colors depend on a number of variables, such as the temperature of the reaction, the duration of the reaction, the concentration and amount of the alkali, the concentration and amount of the metadinitrobenzene, the relative proportions of alcohol and water, and illumination.

Although Oesting<sup>38, 39</sup> develops his colors at room temperature, we have found, as have all other investigators,<sup>36, 37, 40</sup> that it is necessary to control all these factors rigidly. By modifying certain of the aforementioned variables, we increased the sensitivity of the reaction tenfold as compared with Oesting's modification, and succeeded in eliminating the development of interfering browns which affect the accuracy of the colorimetric determinations.

The procedure for color development according to our modification of the Zimmermann reaction for use in the Oesting colorimeter was applied to the assay of crystalline androsterone and dehydroisoandrosterone in the following manner:

Aliquot portions of an alcoholic hormone solution of known concentration are measured accurately into Oesting's colorimeter tubes, using a previously calibrated 1-cc pipette graduated in 0.01 cc. The alcohol is evaporated off carefully over a water bath at 70-75°C., and after cooling the tubes to room temperature, 0.15 cc of 95 per cent ethyl alcohol, 0.2 cc. of 2 per cent metadinitrobenzene in absolute ethyl alcohol and 0.2 cc. of 15 per cent aqueous potassium hydroxide are added to each tube. Their contents are then mixed thoroughly. At the same time a control tube containing identical amounts of the two reagents and alcohol is prepared. The tubes are placed in the dark in a water bath maintained at precisely 25°C. and, with occasional shaking, are kept there for one and a quarter hours. The contents of the tubes are then diluted

to a volume of 7 cc with 95 per cent ethyl alcohol. After being thoroughly mixed, they are assayed immediately in the Oesting colorimeter, which is set up with the necessary precautions to ensure optimal lighting conditions.

Using our modification of the Zimmermann reaction, we first calibrated Oesting's colorimeter with known quantities of crystalline androsterone and dehydroisoandrosterone. Oesting failed to take this precaution and relied wholly on capon assays of urinary androgens (unknowns) for the development of the color and the standardization of the disks in his colorimeter.<sup>38, 39</sup> As a result of our studies we reached the following conclusions:

(1) The intensity of the pink-to-red color which develops is proportional to the amount of hormone present in solution.

(2) The disks of the Oesting colorimeter representing color units below 20 are unreliable for quantitative assays.

(3) When colors are developed by Oesting's method and assayed with his colorimeter, 1 color unit is equivalent to approximately 100% crystalline androsterone, whereas originally he claimed that a color unit was equivalent to  $10 \pm 2$ ; androsterone. According to our method 1 color unit is equivalent to 8.96 to 10.04% crystalline androsterone, depending on the disk used for a given determination. Calibration of the instrument with crystalline androsterone has resulted in the following values for each of the disks:

DISK MARKING	AVERAGE AMOUNT ANDROSTERONE PER UNIT	ANDROSTERONE EQUIVALENT OF EACH DISK
20 units	8.96%	17.97%
28 units	9.04%	25.31%
34 units	9.84%	33.46%
40 units	10.04%	40.16%
50 units	9.63%	48.15%

(4) Crystalline dehydroisoandrosterone gives a more intense pink color per unit of weight than does crystalline androsterone. Quantitatively, it is less of a complicating factor than already exists in the marked differences which are characteristic of the biological activity of these hormones. Further data on this point are being reported in another communication.

Having calibrated each colored disk of Oesting's colorimeter in terms of  $\mu$ -equivalent crystalline androsterone, we then applied our modification of Zimmermann's reaction to the assay of urinary androgens in normal and hirsute women in order to determine whether one could for purely clinical purposes substitute the chemical method for that of bioassay.

## ENDOCRINOLOGY AS NOW PRACTICED\*

ROBERT T. FRANK M.D.†

NEW YORK CITY

**T**ODAY every practitioner of medicine is forced and likes to practice endocrinology. I shall act as commentator of the current methods of treatment, and give you my own views, based on both clinical and laboratory experience. The most expeditious method of covering the subject will be to take up seriatim the symptoms produced by underfunction and overfunction of each gland, with short remarks on the treatments used, their effectiveness and limitations.

### ANTERIOR PITUITARY GLAND

**Underfunction** Before the adult stage has been reached, underfunction produces either the short, obese, Fröhlich type or the doll-like Levi-Lorraine syndrome, as well as the true pituitary dwarf. Anterior pituitary extracts have been used. No extract potent for the human being, either growth-promoting, maturizing or gonadotropic, is available. I have obtained no results by therapy in any of these groups. Many individuals develop into normal adults spontaneously. In the adult, Sim-

mond's disease is produced by failure of anterior pituitary function. Death alone clinches the diagnosis, and no treatment has proved effective. The majority of recoveries occur in cases in which the disease is simulated, usually those of anorexia nervosa. It is conceivable that minor grades of the disease may exist, producing an asthenia similar to that seen with failure of the adrenal cortex. In these cases, if no improvement is produced by a potent cortical extract, Simmond's disease must be suspected.

**Overfunction** Excessive growth is produced in the adolescent group. Giants in the adolescent group suffer because their school contacts are rendered difficult by their excessive size, which is disproportionate to their mental attainments. My efforts to control the rapidity of growth by large doses of androgens in girls and estrogens in the youths have shown no results. X-ray therapy to the pituitary gland, which has been advocated, is too dangerous for me to attempt it. In the adult group, acromegaly is a chronic disease when first seen, and has proved unresponsive to every form of treatment except surgical intervention to save eyesight.

\*Presented at the New England Postgraduate Assembly, Cambridge, November 15, 1938.

†Clinical professor of gynecology, Columbia University College of Physicians and Surgeons; consultant gynecologist, Mount Sinai Hospital, New York City.

of the virilism associated with adrenocortical tumors. We have not yet had the opportunity of making such studies in arrhenoblastoma of the ovary, and thus far neither we nor others have found values of this order in Cushing's syndrome without an adrenocortical tumor.

We have demonstrated, furthermore, that the colorimetric assay of urinary androgens may yield information of prognostic importance, because by means of it we were able to predict the post-operative recurrence of an adrenal tumor about four months before clinical evidence of metastasis was first apparent.<sup>41</sup>

It is also evident that little further can be gained in the investigation of the pathologic physiology of hirsutism and virilism by studying only the total daily androgen excretion. More rapid progress assuredly will be made after it becomes possible to isolate quantitatively and to identify chemically the various urinary androgens. Such investigations may disclose qualitative differences between the androgens of normal and hirsute women. Butler and Marrian<sup>20, 21</sup> have already isolated isoandrosterone and pregnane-3,17,20-triol from the urine of patients with virilism and adrenal hyperplasia; these androgens have not been found in the urine of normal women.

Kenyon et al.,<sup>17</sup> Gallagher et al.,<sup>3</sup> Glass and Bergman<sup>42</sup> and others, who have investigated the androgen-estrogen ratio in normal women and in those with hormonal disturbances, have reported interesting findings on this aspect of the problem. It is quite possible that a relative increase in androgen production, and consequently in excretion, may account for certain types of hypertrichosis. This seems a likely explanation for the hirsutism in one of our patients who developed hypertrichosis during a six-month period of amenorrhea which began at the time of a severe streptococcal infection. With the reappearance of the menses the growth of new hair stopped, but the hair already present remained unchanged.

#### SUMMARY

The quantitative determination of urinary androgens by bioassay has various limitations which curtail its usefulness in the study of the pathologic physiology of hirsutism and virilism and in its practical application to the problems of clinical medicine. For these and other reasons it is proposed to supplant the method of bioassay, for purely clinical purposes, by a chemical technique which necessitates no greater assumptions than are already being made by those who use the bioassay exclusively.

The chemical method of assay is based on a colorimetric reaction (Zimmermann's) by means

of which one may, with significant accuracy, quantitatively assay the crystalline androgens. This method also has been adapted satisfactorily to the assay of urinary androgens.

Oesting's colorimeter has been calibrated in terms of crystalline androsterone, and its limits of accuracy defined. It has been determined that Oesting's modification of Zimmermann's reaction is not adequately sensitive for quantitatively accurate assays. Our own modification of the Zimmermann reaction is about ten times as sensitive as that of Oesting.

The chemical method of assaying urinary androgens gives information of diagnostic and prognostic importance in certain cases of virilism. Preliminary studies have indicated that the androgen excretion for normal young women is the equivalent of 4 to 15 mg androsterone per twenty-four hours, and that patients with benign hirsutism and adrenogenital virilism excrete the equivalent of 1 to 29 mg androsterone per twenty-four hours. In 2 cases of virilism due to adrenocortical tumor the androgen excretion was found to be the equivalent of 45 and 325 mg androsterone per twenty-four hours at various stages of the disease. In 1 of these cases<sup>41</sup> the androgen excretion fell to normal levels immediately after the removal of the tumor, but began to increase again about four months before clinical evidence of recurrence was detected.

Assay of the total urinary androgen excretion, either by the chemical or the biological method, can give only a crude index to the physiology of the male sex hormones until it becomes possible to identify chemically and to assay quantitatively each of the urinary androgens and to establish the physiological relation of the glandular hormones to those excreted in the urine.

## ENDOCRINOLOGY AS NOW PRACTICED\*

ROBERT T FRANK M.D†

NEW YORK CITY

**T**ODAY every practitioner of medicine is forced and likes to practice endocrinology I shall act as commentator of the current methods of treatment, and give you my own views, based on both clinical and laboratory experience The most expeditious method of covering the subject will be to take up serialum the symptoms produced by underfunction and overfunction of each gland, with short remarks on the treatments used, their effectiveness and limitations

### ANTERIOR PITUITARY GLAND

**Underfunction** Before the adult stage has been reached, underfunction produces either the short, obese, Fröhlich type or the doll-like Levi-Lorraine syndrome, as well as the true pituitary dwarf Anterior pituitary extracts have been used No extract potent for the human being, either growth-promoting, maturizing or gonadotropic, is available I have obtained no results by therapy in any of these groups Many individuals develop into normal adults spontaneously In the adult, Sim-

mond's disease is produced by failure of anterior pituitary function Death alone clinches the diagnosis, and no treatment has proved effective The majority of recoveries occur in cases in which the disease is simulated, usually those of anorexia nervosa It is conceivable that minor grades of the disease may exist, producing an asthenia similar to that seen with failure of the adrenal cortex In these cases, if no improvement is produced by a potent cortical extract, Simmond's disease must be suspected

**Overfunction** Excessive growth is produced in the adolescent group Giants in the adolescent group suffer because their school contacts are rendered difficult by their excessive size, which is disproportionate to their mental attainments My efforts to control the rapidity of growth by large doses of androgens in girls and estrogens in the youths have shown no results X-ray therapy to the pituitary gland, which has been advocated, is too dangerous for me to attempt it In the adult group, acromegaly is a chronic disease when first seen, and has proved unresponsive to every form of treatment except surgical intervention to save eyesight

Presented at the New England Postgraduate Assembly Cambridge, November 15 1938

†Clinical professor of gynecology Columbia University College of Physicians and Surgeons consultant gynecologist Mount Sinai Hospital New York City

## POSTERIOR PITUITARY GLAND

Diabetes insipidus, characterized by excretion of 5 to 20 liters of urine per day, is due to a disturbance of the posterior pituitary lobe, sometimes caused by pressure on the hypothalamus. This condition is controlled by appropriate doses of posterior pituitary extract, given by hypodermic injection, under the tongue or intranasally. Intermedin shows no advantages over posterior pituitary extract.

## THYROID GLAND

Thyroid disturbances are sufficiently understood, and require little discussion.

*Underfunction* Cretins, if taken in hand sufficiently early, can be developed into fairly normal individuals. Adults with myxedema can be kept in normal health by desiccated thyroid gland or thyroxin. It must be remembered that the several thyroid preparations vary greatly in strength, and it is well to become acquainted with and stick to one preparation. Thyroid underfunction may produce many by-effects, such as amenorrhea, obesity or abortion. In adolescents, severe menorrhagia is sometimes noted.

*Overfunction* Endemic adolescent goiter no longer forms a public-health problem, thanks to Marine's iodine mass therapy. Patients with exophthalmic or toxic goiter, particularly those with a mild degree of the disease, respond to medical measures, particularly to a placid and protected form of life. For the present, at least, most cases remain largely surgical problems. The use of x ray for the treatment of this condition is risky, for the dose is almost impossible to gauge, and regression is apt to continue for a long time after the treatment has been stopped, with resultant underfunction.

## PARATHYROID GLAND

*Underfunction* If underfunction is acute, tetany is readily relieved by calcium, fluids and parathormone. Chronic tetany, oftenest seen as the result of surgical removal of the parathyroids, shows increasing tolerance to parathormone, and this makes effective relief difficult. Whether the dihydrotachysterol introduced by Holtz will permanently replace parathormone in these patients is as yet undetermined.

*Overfunction* Hyperparathyroidism is due to parathyroid adenoma and produces osteitis fibrosa cystica. It is believed that both scleroderma and osteomalacia are likewise due to parathyroid overfunction. Surgical intervention is indicated, with removal of the adenoma, and sometimes of parathyroid tissue where diffuse hyperplasia appears to exist.

## PANCREAS

*Underfunction* Pancreatic insufficiency causes diabetes mellitus. This disease has been robbed of much of its gravity by the discovery of insulin. I shall not venture to discuss the use of insulin here in the vicinity of Boston, but it should be appreciated that cases difficult to control require special knowledge.

*Overfunction* Hyperinsulinism, with its dramatic and often misleading train of symptoms,—particularly convulsions,—is due to adenoma of the islands of Langerhans. Surgical intervention is called for if the diagnosis is well established. At laparotomy the adenomas may not be discovered, and even at autopsy the multiple small nodules may be difficult to recognize.

## ADRENAL GLANDS

*Underfunction* Addison's disease, due in the vast majority of cases to tuberculosis of the adrenal cortex, proves fatal unless adequate amounts of potent cortical extract are administered. The commercial extracts vary in potency and appear to deteriorate, and are therefore rarely effective. Minor degrees of insufficiency most probably produce severe asthenia and loss in weight, the syndrome then resembling minor grades of Simmond's disease. Such patients should be benefited by a potent cortical extract.

*Overfunction* Overgrowth of the adrenal cortex produces the adrenocortical syndrome. The underlying condition may be carcinoma or hyperplasia. The resulting complex is marked by hirsutism, trunk obesity, polycythemia, high blood pressure, osteoporosis and colored striae. If visualization of the adrenals by means of perirenal insufflation of carbon dioxide shows enlargement, surgical removal of the tumor or resection of the hyperplasia is indicated. As the operation is difficult and dangerous, it is not yet advised for minor degrees of the syndrome.

Overfunction of the adrenal medullary produces extreme hypertension. If such a condition is diagnosed, surgical removal of the paraganglioma is indicated.

Hirsutism, particularly facial hirsutism in women, appears to be due to an adrenal disturbance. Large doses of estrogen have not produced any improvement. Bleaching of the hair and electrolysis appear at the moment to be the sole remedies for this very disturbing disfigurement.

## MALE GONADS

*Underfunction* In the adolescent group hypogonadism, because of the accompanying growth

disturbances, appears almost assuredly a primarily pituitary underfunction. These boys are usually tall and obese, and not infrequently show gynecomastia. The testes are very small, with correspondingly small phallus and prostate. The disturbance is usually noted about the tenth or twelfth year. Often but not invariably cryptorchidism is present. No operative intervention for the latter should be undertaken until at least a year's treatment with the gonadotropic factor, obtained from pregnancy urine, has been tried. This factor, however, does not relieve hypogonadism. The great majority of these adolescents eventually become normal by the nineteenth or twenty-first year. Less than 5 per cent are permanently handicapped. Pituitary glandular extracts are of no avail. If the thyroid function is insufficient, thyroid extract may be given. Androgens are not indicated. Adult hypogonadism cannot be cured. Libido may be temporarily awakened by adequate dosage of androgens in both hypogonad individuals and castrates. At least 25 mg of testosterone, given two or three times a week, is required. No permanent good is achieved by this therapy, and the effect is undoubtedly psychic. Spermatogenesis is not stimulated.

**Overfunction** In adolescent males hypergonadism is a very rare syndrome. I have seen it as early as the sixth year, with full hirsutism, large phallus, strong sex urge and disturbed or defective mentality. These individuals are liable to be arrested for sex delinquencies or crimes. The underlying cause appears to be adrenal hyperfunction. If an enlargement of the adrenal is diagnosable, surgery is indicated, and even if not demonstrated, exploration is justified. The attempt to produce reduction of prostatic hypertrophy with androgens does not rest on a sound basis, and the effects reported are not convincing.

#### FEMALE GOVADS

**Underfunction** Such a condition is not recognizable until the normal time of pubescence. As in the male, the build is usually abnormal, either infantile or eunuchoid. The secondary sex characteristics do not develop. Menstruation does not appear. As the time of menarche is very variable, too early efforts at treatment are to be avoided. This condition is primarily due to prepituitary underfunction. It cannot be influenced by direct measures. The gonadotropic extracts derived from pregnancy urine do not help. Thyroid underfunction demands thyroid extract. Estrogens are of no use. Obesity or malnutrition, both frequent causes, should be corrected by adequate hygienic and dietary measures.

In adults, both primary and secondary amenorrheas, unless due to thyroid insufficiency, obesity, malnutrition or some severe intercurrent constitutional disease, such as tuberculosis, are unresponsive to any form of treatment, the condition almost surely being due to primary prepituitary insufficiency. Huge doses of estrogen (1,500,000 international units) are required to produce a single menstruation, a result which is of little benefit to the patient. Frequently without known cause, menstruation and fertility return after many years of amenorrhea. Likewise conception during a long period of amenorrhea is sufficiently frequent to require mention. Small doses of x-ray to the ovarian regions have restored menstruation and fertility, but in my opinion more cases have been rendered permanently amenorrheic and sterile by this form of therapy\*. Recently, intravenous injection of pregnant mare's serum has produced ovulation and has been followed by pregnancy. The potential dangers inherent in this method of treatment limit its application to very expert hands.

The menopause (both physiologic and that induced by x-ray therapy or by surgical castration) is the most extreme form of underfunction. All its symptoms,—mental, neurovascular, arthritic and digestive,—as well as local atrophies, are relieved by adequate dosage of estrogens. The therapy must be continued at intervals for a long time. Estrogens are specific for the relief of the symptoms of the menopause.

**Overfunction** Hypersecretion of the ovaries is due to prepituitary overfunction. In the majority of cases, menorrhagia and metrorrhagia are the predominant symptoms. It is necessary to exclude anatomic causes for the bleeding, such as cervical lesions, carcinoma and fibroids. Hyperplasia of the endometrium and, if the condition exists for a long time, of the uterine muscle results. In my hands the gonadotropic factors, estrogens as well as androgens, have proved ineffective. Just as in all the other hyperfunctional conditions, surgery is indicated. As a rule, curettage in older patients, followed by intrauterine radium or by x-ray therapy applied to the ovaries, must be resorted to. In the adolescent group, as previously mentioned, 20 per cent show marked hypothyroidism with basal metabolic rates as low as -35 per cent. Thyroid therapy cures these cases. Where the thyroid function is normal, subcutaneous injection of moccasin venom has proved effective, although relapses are frequent, requiring resumption of the treatment.

\*This type of rad therapy requires a carefully graduated dosage. If it is to be employed it must be limited to fully qualified specialists.

\* \* \*

At present the vast majority of overfunctions of any of the glands of internal secretion warrant surgery if the diagnosis can be made. However, in my experience at least 50 per cent of the patients sent to me as having endocrine disease have been found to be suffering from non-endocrine conditions. I therefore emphasize that the search for non-endocrine causes must not be neglected. Only if such causes cannot be found should an endocrine origin be suspected.

In spite of the huge number of so-called endocrine products available, comparatively few are

actually potent. The use of anterior pituitary powder and of mammary, placental, splenic, thymic, pineal and orchitic extracts, foisted on the profession by alluring clinical reports, and reappearing in even more attractive form in some of the pharmaceutical literature, are entirely unjustified. On the other hand, no one can doubt the physiological and clinical value of thyroid extracts, parathormone, estrogens, androgens and potent adrenocortical extract. Their effects on properly selected cases are too specific and indubitable to be overlooked or misinterpreted.

## UNILATERAL RENAL DISEASE WITH ARTERIAL HYPERTENSION\*

Report of a Case Apparently Cured Following Nephrectomy

J DELLINGER BARNEY, M.D.,† AND HOWARD I SUBY, MD‡

BOSTON

**I**N VIEW of the rapidly increasing interest in the association of unilateral renal disease with long-continued arterial hypertension, we report in detail the history of a patient with this interesting combination of circumstances.

L F F, a 10-year-old, white, American girl, entered the Urological Service of the Massachusetts General Hospital through the Emergency Ward on March 16, 1937, complaining of right midabdominal pain of 1 week's duration. The onset was sudden, the pain was steady, dull and non-radiating, and was located below and to the right of the umbilicus. There was no accompanying nausea, anorexia or urinary or bowel symptoms. About 48 hours later an exacerbation of this pain 'doubled her up'. There was still no nausea or vomiting, and the bowels moved after a cathartic. Next day the patient felt much better. Three days before entering the hospital there was another exacerbation of pain, intensified on leaning forward. Subsequent to this an ice bag was applied to the abdomen and a cathartic, followed by an enema, was given.

The patient was said to have had pyelitis 3 years previously, about 2 months previously she had had an attack of burning on urination, but this was apparently of brief duration. She had always been constipated, under-sized and undernourished. The family history was irrelevant except that the mother at the time of the patient's entry was ill with pleurisy.

Examination showed a well-developed but undernourished, sallow child, lying in bed in no apparent distress. The throat was moderately injected, the teeth neglected. The heart and lungs were negative. Abdominal examination showed tenderness and spasm localized over a small area to the right of and below the umbilicus. There was so much muscular spasm that it was difficult to palpate

the region of the right kidney. There was no costo-vertebral tenderness, and no organs or masses could be felt. Peristalsis was normal, there was no psoas spasm, rectal examination was negative. The blood pressure was 185/130, the temperature 99°F, and the pulse and respirations were

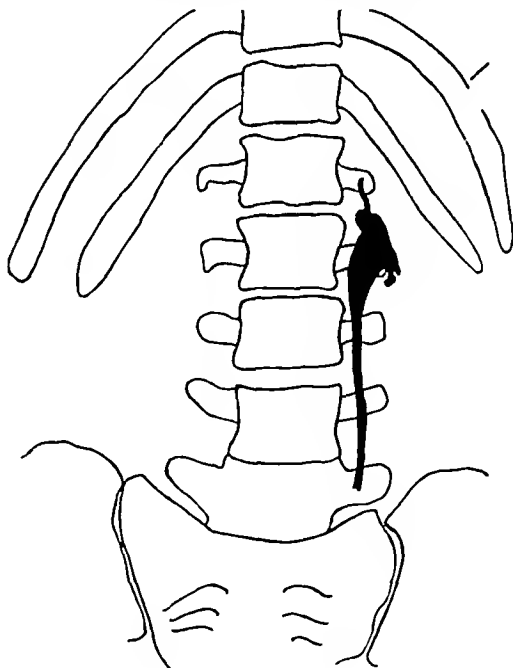

FIGURE 1 Tracing of Right Retrograde Pyeloureterogram

normal. On admission the urine was acid, there was a very slight trace of albumin but no bile, sugar, acetone or diacetic acid. The sediment showed 10 to 20 white cells per high power field. Subsequent urinalyses showed the same findings.

Blood studies showed 4,710,000 red cells, a hemoglobin

of 70 per cent and from 9500 to 12,500 white cells, the differential was normal. The nonprotein nitrogen was 20 mg per 100 cc., the phenolsulfonephthalein excretion was 61 per cent in 2 hours. A blood Hinton test was negative, as was a von Pirquet test. The stool was negative to guaiac.

Roentgenograms of the urinary tract showed the left kidney to be normal in size and position, the right kidney could not be visualized, perhaps because of gas and fecal matter in the colon. An intravenous pyelogram showed good excretion of the dye on the left with a normal pelvis calices and ureter, no dye was excreted by the right kidney. The findings were regarded as indicative of a non functioning right kidney. Plates of the chest were essentially negative.

Cystoscopic examination showed normal bladder and ureters. Catheters were passed without difficulty to either kidney. No urine whatever was obtained from the right that on the left showed no leukocytes. The bladder urine showed 1 to 3 leukocytes per high-power field. A culture of the bladder urine was sterile on one occasion and later showed *Bacillus coli*, the left kidney urine was sterile. A right retrograde pyelogram was done, about 3 cc. of Skiodan being injected. This showed poor filling of the minor calices the pelvis did not appear to be dilated. (Fig. 1)

Subsequently the patient was seen in consultation by various members of the Pediatric Service. It was the consensus of all that we were dealing with an atrophic, functionless and probably infected right kidney. This, together with the fact that several blood-pressure readings showed persistent hypertension, the figures varying from 185/130 to 200/170, led to the opinion that the case was probably one of hypertension resulting from unilateral renal disease and that nephrectomy was indicated.

At operation on March 31 (by J. D. B.), an oblique incision was made in the right loin. A kidney about one quarter normal size was found lying in a normal position. It was quite firm and fibrous, and not adherent. There were no abnormal vessels noted, and the pelvis and ureter looked normal. The kidney was removed without incident. A drain was placed in the depths of the wound, which was then closed around it in layers.

The pathological report gave a diagnosis of healed pyelonephritis with renal atrophy, and was as follows:

Gross examination shows a kidney measuring 5 by 2 by 1 cm. The surface is smooth pinkish gray and glistening. On section the kidney substance measures 1 mm. in thickness and is soft. The pelvis is dilated. The mucosa is grayish smooth and glistening. The ureter measures 4 cm. in length and is slightly injected but otherwise negative.

The vessels appear normal but quite small. Immediately beneath the epithelium in one calyx is an extensive infiltration of lymphocytes, mononuclears, and occasional eosinophils. Other scattered foci of lymphocytic infiltration are found throughout the organ. Some times there is follicle formation. No abscesses are present. The parenchyma shows extensive atrophy, with sclerosis of many glomeruli and marked tubular atrophy. Throughout the kidney marked vascular changes are present, consisting chiefly of intense thickening in the smaller arteries and arterioles. This is most marked in the areas of parenchymal atrophy but is not limited to them. The cause of the renal atrophy cannot be determined with certainty, but the picture is consistent with a burned-out pyelonephritis. (Fig. 2)

Convalescence from operation was brief and uneventful. Twenty-four hours later the blood pressure had dropped to 110/70, at about which point it remained until she was discharged. While in the hospital after operation, a few pus cells were found in the urine and a culture showed *B. coli*. After the patient was put on an acid-ash diet and

FIGURE 2. Photograph of Kidney Cortex

mandelic acid the urine became pus-free and sterile, and has remained so ever since.

During the 21 months since operation the patient has been seen at frequent intervals and the blood pressure has been checked. The systolic pressure has been a little over 100, but the last reading, taken on December 7, 1938, was 98/60.

From the time of Bright<sup>1</sup> it has been realized that certain forms of cardiovascular disease in man cause pathologic changes in the kidney and that hypertension may be the result of diffuse vascular disease with kidney involvement. Fahr<sup>2</sup> regards hypertension as a compensatory phenomenon to offset the reduced blood flow through the diseased kidney. Volhard and Suter,<sup>3</sup> however, believe that there is a humoral mechanism of renal origin as a cause of hypertension. From a review of the literature it seems obvious that even those who regard certain cases of hypertension as of renal origin cannot explain its mechanism.

Various experimental procedures, all aimed at producing an elevation of blood pressure, have been carried out in animals. These have given

varied but not constant results Goldblatt<sup>4</sup> and his co-workers have done what is perhaps the most convincing work in this direction. By partial occlusion of the renal arteries with a silver clamp they were able to produce a renal ischemia accompanied by hypertension. Their experiments indicate that at least experimental hypertension is due primarily to a humoral and not to a nervous mechanism. While the exact nature of the effective humoral substance has not yet been determined, it seems probable that it works in conjunction with the adrenocortical hormone in the production of hypertension in man.

In connection with the case which we have reported, it is interesting, perhaps valuable, to review the cases of unilateral renal disease occurring on the Urological Service at the Massachusetts General Hospital. Beginning with 1911 we have reviewed to date the records of all such cases with a diagnosis of pyonephrosis, pyelonephritis, hydronephrosis or pyelitis. There was a total of 305, of which 224 were nephrectomized. Women outnumbered men, 171 to 134. Seventy-six cases, or 25 per cent, had hypertension—a preoperative systolic blood pressure of at least 140 mm of mercury. Since Cabot<sup>5</sup> regards 110 to 135 mm as the normal range of systolic blood pressure, we have arbitrarily taken pressures of 140 mm or higher as evidence of hypertension but realize that this figure may be questioned.

It is obvious that an investigation of this kind in order to be of value should include a complete follow-up. Unfortunately for our present purpose, the importance and value of taking postnephrectomy blood-pressure readings have but just been

realized, and although many of the patients, whether or not operated on, were seen in the clinic at varying times after leaving the hospital, the blood pressures were taken in but 15 cases.

Of these patients, all of whom were nephrectomized and seen from four months to nine years after operation, 10, or 67 per cent, showed an average drop in systolic pressure of 30 mm, as compared with the preoperative level.

#### COMMENT

We consider the case reported to be an unusual example of unilateral renal disease, associated with and probably causing hypertension, and cured for twenty-one months by nephrectomy. There are few if any similar cases which have been closely observed for this length of time after operation.

We do not wish to put undue stress on the investigation of the cases from the Urological Service. It seems to us, however, that it indicates the importance of carefully studying and following up cases of unilateral renal disease, especially from the point of view of hypertension, both before and after operation. This procedure may result in the discovery that so-called renal hypertension is commoner than we have supposed.

# REPORT ON MEDICAL PROGRESS

## DIAGNOSTIC ROENTGENOLOGY

RICHARD SCHATZKI, M.D. \*

BOSTON

ROENTGENOLOGY is a field which is so intimately connected with most other specialties that advances in any of the latter naturally stimulate progress in the former, and conversely, developments in roentgenology favorably influence the other specialties. Progress in diagnostic roentgenology is commonly due to the introduction of new methods, but a different use of established types of examination often produces essential diagnostic improvements. Slight changes in the appearance of a roentgenological picture, recognized for many years and thought to be unimportant, after intensive study directed to this particular point, at times prove to be the only visible sign of an important pathologic lesion. On the other hand, small variations may have been overlooked for decades before being described. Examples of advances due to changes both in method and in interpretation present themselves in the review of recent progress in diagnostic roentgenology.

### HEART

For many years it has been a dream of roentgenologists and cardiologists to be able to see not only the comparatively undifferentiated shadow of the outside of the heart but also the shadow cast by the heart chambers themselves. In recent years, roentgenological studies of intracardiac calcifications (calcified valves, calcified annulus fibrosus, and so forth) and their movements have shown how complicated the physiology of the interior of the heart is and how little we know about it (Sosman and Wosika<sup>1</sup>).

These investigations only increased the hope that a method of exploration of this roentgenological *terra incognita* might be found. After unsuccessful attempts by many authors, Robb and Steinberg<sup>2</sup> in 1938 succeeded in obtaining pictures of the inside of the hearts of living men. By rapidly injecting approximately 35 cc. of 70 per cent Diodrast — the non-radioactive organic iodine compound which is routinely used in weaker concentration for intravenous pyelography — into the cubital vein, they obtained radiographic pictures of the following structures: the superior vena cava and its tributaries, all four heart chambers, the ventricular walls, the interventricular septum, the

tricuspid, pulmonic and aortic valves, the pulmonic and aortic sinuses, the pulmonary arteries and the thoracic aorta. The flow of the dye was so rapid that not all these structures were seen simultaneously, and preceding tests (ether test, cyanide test) were necessary in order to determine the optimal moment of radiographic exposure for a certain structure in a given patient.

The experience of these authors suggests that the method is not dangerous. It is not yet possible to obtain consistently a picture of any part of the cardiopulmonary circulation desired and failures are to be expected. In principle, however, the method has solved the above-mentioned problems, though improvements are necessary and are to be hoped for. The value of this method for the study of the physiology and pathology of the chest is obvious. Its prospects of becoming important in clinical medicine are excellent.

It will be helpful in many ways, such as in the differentiation of rheumatic and congenital heart lesions, in the differential diagnosis of mediastinal tumors and aneurysms, in the study of venous flow in constrictive pericarditis and in the determination of locus and cause of obstruction in upper mediastinal syndrome.

### PULMONARY DISEASES

Considerable progress has taken place in recent years in the roentgen examination of pulmonary diseases. This progress is characterized by the recognition of the role which mechanical factors play in roentgenological changes. Instead of describing "shadows," roentgenologists have become interested in the mechanical factors causing them, in other words, the parenchymal changes are studied as secondary to those in the bronchi and vessels. Obstructing lesions of the bronchi may produce atelectasis or, by a ball-valve mechanism in less complete cases, localized emphysema of the involved lung segment. Changes in the position of the diaphragm and mediastinum, as well as variations in the size and position of the hilar shadows, commonly occur. Secondary pneumonic and purulent processes with bronchiectasis and cavity formation may take place in the atelectatic areas.

Of course, not all pathologic changes can be

\*Lecturer in roentgenology, Harvard Medical School, roentgenologist, Massachusetts General Hospital.

varied but not constant results Goldblatt<sup>4</sup> and his co-workers have done what is perhaps the most convincing work in this direction. By partial occlusion of the renal arteries with a silver clamp they were able to produce a renal ischemia accompanied by hypertension. Their experiments indicate that at least experimental hypertension is due primarily to a humoral and not to a nervous mechanism. While the exact nature of the effective humoral substance has not yet been determined, it seems probable that it works in conjunction with the adrenocortical hormone in the production of hypertension in man.

In connection with the case which we have reported, it is interesting, perhaps valuable, to review the cases of unilateral renal disease occurring on the Urological Service at the Massachusetts General Hospital. Beginning with 1911 we have reviewed to date the records of all such cases with a diagnosis of pyonephrosis, pyelonephritis, hydronephrosis or pyelitis. There was a total of 305, of which 224 were nephrectomized. Women outnumbered men, 171 to 134. Seventy-six cases, or 25 per cent, had hypertension—a preoperative systolic blood pressure of at least 140 mm of mercury. processes produced by the ulcer, and to decide, more frequently than before, whether or not an ulcer is active

This technic has enabled the roentgenologist to show changes in some cases of gastritis. Above all, the roentgenological diagnosis of lesions of the gastrointestinal tract has been put on a more secure basis. The films obtained by this method represent the optimal fluoroscopic picture, so much so that they allow the study of the fluoroscopic image to continue without the patient's being present, and thereby make the diagnosis more certain in difficult cases. Except for color it is possible to obtain a picture of the inner surface of the gastrointestinal tract comparable to that which the pathologist sees when he looks at the opened specimen.

Ulcerated lesions which, owing to the changes in the vicinity of the ulcerations, are clearly malignant on inspection can be recognized as such roentgenologically. The differentiation of benign ulcers and those which grossly appear to be benign, but prove to be malignant histologically, still defies the efforts of any macroscopic type of examination, including roentgenology.

#### GALL BLADDER

Roentgenological examination of the gall bladder has a fair percentage of failures. Usually, the failure is due to the fact that small stones, due either to respiratory or pulsatory motion or to the small size of the stones compared with the density of the overlying dye, are not visible within a dye-filled gall bladder. Recent technical and methodical developments have tended to decrease the number of these errors.

One definite advancement has been the introduction of the examination of the dye-filled gall bladder in the upright position (Åkerlund,<sup>10</sup> Bernstein,<sup>11</sup> Ettinger<sup>12</sup>). Since most stones sink to the bottom of the gall bladder in this position, they are crowded in a small space at the fundus and are therefore more easily recognized than on films taken with the patient in the usual prone position, and overlying gas shadows can be more easily differentiated. The peculiar phenomenon of stones floating at a certain level in the dye has been described by these authors and has been confirmed by others. This examination is particularly valuable if done under fluoroscopic control.

A remarkable technical development is the construction of x-ray tubes with a rotating anode. In such a tube, the heat developing in the focal spot of the anode is distributed over a large area, and the use of a small effective focal spot together with a large load given in a fraction of a second is

possible. In the resulting films, excellent definition is present, and small biliary concretions are demonstrable with greater regularity than they have been heretofore.

#### SPINAL CANAL

It was a definite step forward when Camp<sup>13</sup> reported that slight pressure defects of the bony spinal canal produced by lesions, usually tumors, could be demonstrated. Unless the tumor was big, however, a diagnosis from the flat film was possible only when the tumor was localized in a favorable position. An examination following intradural injection of a contrast substance was therefore still necessary in many cases of intraspinal lesions. For this purpose Lipiodol remains the most reliable substance. The examination of small lesions of the spinal canal with this contrast medium has been markedly improved, with resulting discovery of characteristic pictures in posterior rupture of the intervertebral disks (Hampson and Robinson<sup>14</sup>). The fluoroscopic examination of the Lipiodol-filled spinal canal approaches that of the gastrointestinal canal in accuracy. But unless removed during operation, the Lipiodol remains indefinitely in the dural sac. In spite of this, the cases of permanent ill effects attributable to the presence of the oil are comparatively rare.

In a search for a more inert contrast substance, Young and Scott,<sup>15</sup> among others, have advocated the use of a gas. They were able to demonstrate even small ruptured disks after the introduction of air in the dural sac. Other examiners have not been so successful. It is advisable, however, to try an air examination of the spinal canal in cases of block before resorting to Lipiodol. The ideal contrast substance for the examination of the spinal canal has not yet been found, and therefore exact indications must be present before the present substances are employed.

#### ENCEPHALOGRAPHY AND VENTRICULOGRAPHY

In recent years the frequency with which air has been introduced into the cranial cavity for the study of non-neoplastic intracranial lesions has constantly increased, while there is a general tendency to decrease, if possible, the number of air injections in patients with questionable brain tumor. The intensive efforts of making a correct diagnosis and localization from the clinical findings, the electroencephalogram and a careful study of the flat films of the skull are, however, successful only in a comparatively small group of patients. In the large majority of cases an examination after intraventricular or intralumbar injection of air is still necessary. While no revolutionary changes

explained on this basis. But the stress laid by authors<sup>3-5</sup> in various countries on the study of these mechanically produced changes has resulted in the explanation of a number of patterns in the x-ray films of the lungs, the origin of which had not been known hitherto. For instance, horizontal lines in the lower lung fields were found to be due to small, plate-like areas of atelectasis (Fleischner<sup>4</sup>) again, so-called pictures of interlobar effusion were found to be produced by atelectasis (Hampton and King<sup>5</sup>).

This newer viewpoint made possible the recognition of the etiologic factor in cases of severe one-sided pulmonary disease, for example bronchial obstruction due to benign adenoma with secondary complete destruction of one lung. It decreased the number of lesions which had been erroneously called tuberculosis. More important, it led to the correct diagnosis in cases in which a small bronchial tumor or bronchial tuberculosis had produced bronchiostenosis with changes in the x-ray picture—variations which might readily escape the attention of an examiner unfamiliar with these studies. A slight displacement or a decrease in size of a hilar shadow, or a localized area of emphysema, for instance, might be the only abnormality visible in such a case. In addition these studies have decreased the number of so-called negative x-ray films in cases with hemoptysis.

The causes of bronchial obstruction are numerous: mucus, blood, foreign body, tumor, tuberculous and other inflammatory disease of the bronchial wall, pressure from outside by large lymph nodes, mediastinal tumor or aneurysm. The x-ray examination without contrast substance can often lead only to the diagnosis of bronchial obstruction and its location, whereas the etiology has to be established by clinical examination, bronchoscopy or lipiodol examination of the bronchi.

The progress in roentgenological examination of the chest is a characteristic example of the beneficiary effect of co-ordination of medical specialties. Advances in thoracic surgery have allowed operative control in many previously unsolved cases. They tremendously stimulated interest and therewith progress in thoracic roentgenology, the results of which in turn were used for the problems of thoracic surgery.

Hampton and Castleman<sup>6</sup> studied pulmonary embolism and infarction by comparing postmortem teleroentgenograms with the pathologic findings within lungs which had been distended by formalin to their normal size. They found that infarcts were more often visible on films than had been assumed. They were always subpleural, were particularly frequent in the lung edges and had

a characteristic roentgenologic appearance. Though the infarct usually decreased in size gradually and healed with scar formation, these authors have seen cases with rapid resolution of the x-ray shadow without necrosis or scar formation (in complete infarct). The incidence of embolism and infarcts in nonsurgical and in noncardiac cases without clinical evidence of phlebitis was striking. The roentgenological recognition of pulmonary embolism without infarction has been made only in exceptional cases in which extensive embolism was followed by thrombosis of the pulmonary arteries and the formation of a cor pulmonale. Usually such embolism is thought to produce no roentgenologic changes. It is therefore of great interest to note that Westermarck<sup>7</sup> described segmental pulmonary anemia, resulting in a narrowing of the lung vessels and localized increased brightness, as a sign of pulmonary embolism.

#### GASTROINTESTINAL TRACT

Within the last decade, roentgenology of the gastrointestinal tract has gone through a developmental stage which should be reported briefly, even though no unusual contribution has been made within the last year. This development, which started in various countries, and the main banner-bearers of which were Forssell<sup>8</sup> and Berg,<sup>9</sup> did not appear in this country until rather recently. It is characterized by the stress laid on the demonstration of the inner relief of the organs of the gastrointestinal tract. A barium coating is applied, thin enough to leave the elevations of the inner surface free while the valleys are filled. An x-ray examination at this stage of filling shows a picture of the relief of the whole inner surface of the organ, not only a shadow of its mass. In addition, a technical improvement has been developed which allows taking pictures during fluoroscopy, thus permitting the exact instantaneous fixation of a fluoroscopic image (so-called "spot" or aimed film).

This new orientation has led to the roentgenological demonstration of esophageal varices, and hence to the diagnoses of cirrhosis of the liver and of thromboses of the portal and splenic veins, and the differential diagnosis of splenomegaly has been markedly improved. The etiology of hematemesis has been established in many cases by the demonstration of varices. More commonly than before, small lesions, particularly tumors of the stomach and colon, are discovered roentgenologically and small ulcers in unusual positions are demonstrated. The high frequency and exactness with which the actual ulcer crater is demonstrated allow one to differentiate the ulceration itself and cicatricial

processes produced by the ulcer, and to decide, more frequently than before, whether or not an ulcer is active

This technic has enabled the roentgenologist to show changes in some cases of gastritis. Above all, the roentgenological diagnosis of lesions of the gastrointestinal tract has been put on a more secure basis. The films obtained by this method represent the optimal fluoroscopic picture, so much so that they allow the study of the fluoroscopic image to continue without the patient's being present, and thereby make the diagnosis more certain in difficult cases. Except for color it is possible to obtain a picture of the inner surface of the gastrointestinal tract comparable to that which the pathologist sees when he looks at the opened specimen.

Ulcerated lesions which, owing to the changes in the vicinity of the ulcerations, are clearly malignant on inspection can be recognized as such roentgenologically. The differentiation of benign ulcers and those which grossly appear to be benign, but prove to be malignant histologically, still defies the efforts of any macroscopic type of examination, including roentgenology.

#### GALL BLADDER

Roentgenological examination of the gall bladder has a fair percentage of failures. Usually, the failure is due to the fact that small stones, due either to respiratory or pulsatory motion or to the small size of the stones compared with the density of the overlying dye, are not visible within a dye-filled gall bladder. Recent technical and methodical developments have tended to decrease the number of these errors.

One definite advancement has been the introduction of the examination of the dye-filled gall bladder in the upright position (Åkerlund,<sup>10</sup> Bernstein,<sup>11</sup> Ettinger<sup>12</sup>). Since most stones sink to the bottom of the gall bladder in this position, they are crowded in a small space at the fundus and are therefore more easily recognized than on films taken with the patient in the usual prone position, and overlying gas shadows can be more easily differentiated. The peculiar phenomenon of stones floating at a certain level in the dye has been described by these authors and has been confirmed by others. This examination is particularly valuable if done under fluoroscopic control.

A remarkable technical development is the construction of x-ray tubes with a rotating anode. In such a tube, the heat developing in the focal spot of the anode is distributed over a large area, and the use of a small effective focal spot together with a large load given in a fraction of a second is

possible. In the resulting films, excellent definition is present, and small biliary concretions are demonstrable with greater regularity than they have been heretofore.

#### SPINAL CANAL

It was a definite step forward when Camp<sup>13</sup> reported that slight pressure defects of the bony spinal canal produced by lesions, usually tumors, could be demonstrated. Unless the tumor was big, however, a diagnosis from the flat film was possible only when the tumor was localized in a favorable position. An examination following intradural injection of a contrast substance was therefore still necessary in many cases of intraspinal lesions. For this purpose Lipiodol remains the most reliable substance. The examination of small lesions of the spinal canal with this contrast medium has been markedly improved, with resulting discovery of characteristic pictures in posterior rupture of the intervertebral disks (Hampton and Robinson<sup>14</sup>). The fluoroscopic examination of the Lipiodol-filled spinal canal approaches that of the gastrointestinal canal in accuracy. But unless removed during operation, the Lipiodol remains indefinitely in the dural sac. In spite of this, the cases of permanent ill effects attributable to the presence of the oil are comparatively rare.

In a search for a more inert contrast substance, Young and Scott,<sup>15</sup> among others, have advocated the use of a gas. They were able to demonstrate even small ruptured disks after the introduction of air in the dural sac. Other examiners have not been so successful. It is advisable, however, to try an air examination of the spinal canal in cases of block before resorting to Lipiodol. The ideal contrast substance for the examination of the spinal canal has not yet been found, and therefore exact indications must be present before the present substances are employed.

#### ENCEPHALOGRAPHY AND VENTRICULOGRAPHY

In recent years the frequency with which air has been introduced into the cranial cavity for the study of non-neoplastic intracranial lesions has constantly increased, while there is a general tendency to decrease, if possible, the number of air injections in patients with questionable brain tumor. The intensive efforts of making a correct diagnosis and localization from the clinical findings, the electroencephalogram and a careful study of the flat films of the skull are, however, successful only in a comparatively small group of patients. In the large majority of cases an examination after intraventricular or intralumbar injection of air is still necessary. While no revolutionary changes

have taken place in the method or interpretation of cerebral air injection, the appearance of excellent summarizing reports on the normal encephalogram (Davidoff and Dyke<sup>16</sup>) and the pathologic ventriculogram (Lysholm et al<sup>17</sup>) is worth reporting

#### SOFT TISSUES

Roentgenology of the soft tissues is based on a fundamental principle. In respect to x-rays, air is less dense than fat, and fat less dense than the rest of the soft tissues of the body, all the latter being of comparatively equal density. The extensive distribution of fat in fascia and in other parts of the body produces enough contrast to give shadow pictures of muscles and internal organs. Carty<sup>18</sup> in particular emphasizes the importance of the resulting pictures. Edema produces a fairly characteristic pattern, the early recognition of which may be helpful in the diagnosis of inflammatory disease. This technic is of particular help in the diagnosis and differential diagnosis of soft-tissue tumors. The size, the shape and, when present, the capsule of a tumor can be visualized. Lipoma and hemangioma produce almost pathognomonic pictures, the former by the radiolucency of the tumor, the latter by its wormlike structure. The results obtained in the diagnosis of cancer of the breast from such an examination have, as a whole, been rather disappointing. On the other hand, soft-tissue films have become a routine procedure in the diagnosis and treatment of tumors of the pharynx and larynx.

In order to improve the results of the roentgenography of soft tissues, Gratz<sup>19</sup> recommended the intrafascial injection of air. Although this procedure may be of help in some cases, it is usually not necessary.

#### PLACENTA PREVIA

A few years ago, Ude and Urner<sup>20</sup> devised a roentgenological method of diagnosing placenta previa. They injected a small amount (25 to 40 cc) of a contrast substance, for example sodium iodide, into the bladder. The distance between the inner wall of the bladder and the presenting head of the fetus is normally not more than 1 cm, in placenta previa, however, it is greater. Recent reports from other authors<sup>21</sup> confirm these observations. The main value of the method seems to lie in the exclusion of placenta previa. Erroneous positive diagnoses may be due to blood clots or presenting soft tissues, but are said to be avoidable if the whole clinical picture is taken into careful consideration. Even though the fetal head and bladder may have a normal relation by x-ray examination, placenta previa may exist on the posterior wall of the uterus behind the head.<sup>22</sup> The results

of this type of examination have therefore to be accepted with reservation.

#### CONTRAST DEMONSTRATION OF LIVER AND SPLEEN

Ten years have passed since Radt<sup>23</sup> and Oka<sup>24</sup> discovered that colloidal thorium dioxide (Thorotrast), when injected intravenously, accumulated in the reticuloendothelial cells of the liver and spleen, thus allowing a roentgenological demonstration of these organs. The potential danger of the radioactivity of the injected substance immediately brought out protests against its use for diagnostic purposes. The time which has since elapsed allows us to evaluate better the arguments pro and con. There is no doubt that Thorotrast remains in the body almost indefinitely, for example, five years after injection 27 per cent of the substance has been found in the liver alone.<sup>25</sup> Several reports showed, though not absolutely convincingly, evidence of late damage, such as fibrosis in the liver, spleen and adjacent organs.<sup>26</sup> The radioactivity of the amount of Thorotrast used was shown to approach that of minimal doses of radium which have been proved to produce chronic radium poisoning. Nevertheless, other authors<sup>27</sup> have stressed the absence of any demonstrable injury in a group of cases observed over a period of several years.

On the whole, there remained enough doubt in the minds of most roentgenologists to prevent the indiscriminate use of this substance for the demonstration of the liver and spleen. Furthermore, with the passage of time there is now less necessity for such a contrast demonstration. Ordinarily, the outlines of the liver and spleen can be recognized on good flat films of the abdomen. Finally, the differential diagnosis of questionable tumors in the left upper abdomen, as well as the diagnosis of cirrhosis of the liver, has been greatly improved by the roentgenological demonstration of esophageal varices. However, a nontoxic dye permitting the visualization of healthy liver parenchyma should be of great practical value, particularly in the search for liver metastases. It is therefore of interest that Beckermann and Popken<sup>28</sup> have recently succeeded in visualizing the liver and spleen by the intravenous injection of colloidal organic iodine compounds. These substances are not radioactive and are apparently nontoxic. If the preliminary report is confirmed, a new field for routine roentgenological examination seems to be opened up.

#### KYMOGRAPHY AND BODY SECTION ROENTGENOGRAPHY

Among the roentgenological methods which have been introduced in recent years are two which require mention because they involve interesting technical procedures and because they have been widely discussed. They are kymography and body section roentgenography.

Kymography is a method which demonstrates different phases of the motion of an organ on a single film. In order to get such a picture, a grid with several narrow slits is placed between the patient and the cassette. By moving the cassette during a comparatively long exposure, a record of the motion of those parts of the organ seen through the slits is obtained. In other words, the type, speed, rate and extent of motion can be studied roentgenologically on a single film. Stumpf<sup>29</sup> deserves the main credit for the development of this method, which has been introduced in this country by Hirsch<sup>30</sup> and Scott and Moore<sup>31</sup>. The procedure has been extensively used for the study of the heart and vessels, to a lesser degree for that of the lungs, diaphragm and gastrointestinal organs. It has proved of interest in scientific research, but its clinical value has been thus far limited to a small number of cases, those, for instance, in which cardiac aneurysms could be demonstrated, or in which a differentiation of mediastinal tumor and an aneurysm was made possible. Kymography offers an excellent way of obtaining a permanent record of motion of an organ if needed for later comparative studies.

The aim of body section roentgenography, or planigraphy, is the roentgenological demonstration of a certain plane of a body by blurring every shadow produced by parts of the body above and below this plane. The blurring effect is obtained by moving the tube and film during the exposure in such a way that the resting-point of the axis of this movement lies in the desired plane. Its shadow is therefore well defined while everything else is erased by motion.

The principle of this method is relatively old. Recent applications have been reported under various names—laminagraphy, planigraphy, tomography, x-ray focussing device, and so forth. In this country Kieffer<sup>32</sup> and Moore<sup>33</sup> have emphasized the importance of the method. The isolated demonstration of a tissue disk of 5-mm thickness becomes possible. In the demonstration of areas difficult to examine, owing to dense overlying structures, for example the sternum or the sternoclavicular joint, the value of this procedure is obvious. In the study of pulmonary disease (studies of cavities, bronchi and so forth) those who have used it praise it. Further use will show whether the method has general clinical value beyond the study of exceptional cases. The introduction of a simple planigraphic mechanism which can easily and without great expense be added to any Bucky table (Twining<sup>34</sup>) will probably popularize the method and allow its value to be judged on a broader base.

#### MOVING PICTURES AND PHOTOGRAPHY OF THE FLUOROSCOPIC SCREEN

A roentgenological record of the motion of the internal organs has been attempted for many years. More or less crude films were obtained by the use of revolving x-ray tubes and films (direct method) or by photography of the image on the fluoroscopic screen (indirect method). Recent improvements in fluoroscopic screens, photographic films and lenses have resulted in the production of roentgenological moving pictures of distinct value.<sup>35, 36</sup> Up to sixteen pictures can be taken per second, and even the fast-swallowing act has been recorded successfully. The teaching value of such a method is obvious. The same motion can be demonstrated to students again and again without endangering the patient. It is possible that diagnostic progress may also be obtained by this method.

The same improvements which allowed successful screen filming have made simple screen photography possible.<sup>37</sup> In other words, instead of using a large x-ray film one is able to photograph the screen image of a patient's chest on a small photographic film, and to study it directly or after magnification. Though such a method cannot be substituted for the routine methods of examination, its advantages in the examination of large groups of persons—soldiers, students, and so forth—are obvious.

## CASE 25181

## PRESENTATION OF CASE

*First Admission* A sixty-four-year-old married colored Bermudian janitor was admitted complaining of inability to void of two days' duration.

For the past year he had noticed increased slowing of the urinary stream. For several months he had had dyspnea on exertion and orthopnea, as well as transient edema of the ankles. During the previous two weeks he had taken digitalis. He had not had precordial pain. There was no history of rheumatism. He had no knowledge of syphilis.

Physical examination showed a well-developed, thin, colored man who was moderately short of breath. Each eye showed a marked arcus senilis but was otherwise negative. The neck veins were not engorged. There was moderate enlargement of the heart to the left. The apical first sound was loud, with a faint, poorly transmitted systolic blow.  $A_2$  was accentuated and tympanic,  $P_2$  was also loud. A faint diastolic murmur was heard along the left border of the sternum. There were frequent extrasystoles. The blood pressure was 130 systolic, 50 diastolic. Examination of the lungs showed rales at both bases and signs consistent with a moderate amount of fluid in the left pleural cavity. The liver was questionably palpable. There was no edema. The prostate was symmetrically enlarged, being three times normal size.

The temperature was 100.5°F, the pulse 95, and the respirations 48.

Examination of the urine showed a trace of albumin and 30 to 50 red cells and 5 to 10 white cells per high-power field. The blood showed a red-cell count of 3,950,000 with 70 per cent hemoglobin, and a white-cell count of 9600. A blood Hinton test was positive, and the Wassermann test weakly positive. The nonprotein nitrogen of the whole blood was 32 mg per 100 cc. An electrocardiogram showed slight left-axis deviation, low  $T_1$  and diphasic  $T_2$  and  $T_3$ .

An intravenous pyelogram showed prompt excretion of the dye on the right side, slight delay on the left. The kidney pelvis were negative. There was evidence of Pagen's disease in both ilia and in the second lumbar vertebra. X-ray films

of the chest showed the heart enlarged in the region of the left ventricle. There was increased density in the left lower and middle lung fields. The right costophrenic angle was clear. A lateral view showed that the area of increased density lay posteriorly, having a well-defined anterior convexity. There was a localized area of decreased density in the anterior mediastinum just above the diaphragm, with a well-defined border of slightly increased density. The intercostal spaces on the left side were narrowed, and there was some periosteal new bone formation about several ribs.

On the third hospital day a bilateral vasectomy was done. The patient was taught to catheterize himself, given digitalis and sent home on the twenty-first hospital day. He was to return for prostatectomy after improvement of his general condition.

*Final Admission* (three months later) He complained of severe dyspnea and orthopnea of six days' duration, without chest pain. Four and a half grains of digitalis daily had been continued. Three days before re-entry he vomited once.

Physical examination showed the patient in marked respiratory distress, with Cheyne-Stokes respiration. The pupils were large and reacted well. The neck veins were full. The tongue was cyanotic. Examination of the heart was essentially the same as on the previous examination. The blood pressure was 130 systolic, 60 diastolic. The lungs showed rales at both bases, with evidence of a moderate amount of fluid at the right base. The liver edge was not palpable. There was no edema.

The temperature was 98.6°F, the pulse 140, and the respirations 25.

The urine showed a slight trace of albumin. The blood showed a red-cell count of 4,700,000 with 86 per cent hemoglobin, and a white-cell count of 16,100 with 92 per cent polymorphonuclears. The serum nonprotein nitrogen was 45 mg per 100 cc. A blood Hinton test was positive, a Wassermann test weakly positive.

The patient was kept in a cardiac bed and given oxygen and carbon dioxide without improvement. An electrocardiogram on the second hospital day showed a variable P-R interval due to ventricular escape. The ventricular rate was 90.  $T_1$  and  $T_2$  were inverted,  $T_3$  diphasic, and  $T_4$  showed late inversion. On the third hospital day the patient was semicomatose and did not respond to various stimulants. The respirations were 32, the temperature 98°F, and the pulse 95. The blood pressure had risen slightly. On the following day there was no change, but on the fourth day the patient rapidly became worse, the respirations ris-

DR SPRAGUE Could you say anything about the aorta in the lateral view?

DR HAMPTON I think it is diffusely dilated. I do not see any aneurysm.

DR SPRAGUE There would seem to be a definite increase in the first portion of the arch.

DR HAMPTON It is dilated.

DR SPRAGUE One might assume, on hearing the discussion, that these findings were present before and after he came back. What was found at the right base was in addition to what he had had at the left base, and was no doubt due to congestive failure. This left basal lesion with its relation to the diagnosis of syphilis is the bothersome thing.

At the time of his final entry there was very severe dyspnea and orthopnea without pain and signs of increasing congestive failure, with a febrile episode at the end which was probably due to a pneumonic process. I am trying to hook this up into one diagnosis, that of a syphilitic process.

You do not see anything in this chest film that makes you think he had any metastatic lesion from the prostate?

DR HAMPTON No.

DR SPRAGUE The other findings at the end of his illness are of no help in making a diagnosis.

He was an arteriosclerotic individual who was very ill and who probably had a diffuse syphilitic aortitis. From what evidence we have, it is not possible to say he had an aneurysm of the descending aorta with pulmonary collapse. He may have had some aneurysmal dilatation of the arch or even of the intrapericardial portion of the aorta, and the story certainly suggests progressive narrowing of the coronary ostia. I am unable to connect the signs at the left base with the underlying condition but am unwilling to guess at anything other than a syphilitic process in the pleura. The final cardiac episode with this type of arrhythmia and dissociation can well be explained by the large doses of digitalis.

DR F DENNETTE ADAMS How often do you see a syphilitic patient die of congestive failure with no more evidence of valvular damage than this man showed?

DR SPRAGUE I have to invoke involvement and narrowing of the coronary ostia. With such lesions, syphilitic patients may die with severe dyspnea and congestive failure and without a great deal of peripheral edema.

DR CHAMP LYONS These blebs are not numerous enough to assume that emphysema precipitated cardiac failure?

DR SPRAGUE One would think in such a case that there would be some evidence of right-sided

strain, such as cor pulmonale, rather than left-sided cardiac hypertrophy.

DR LYONS Could not prolonged toxemia from suppuration in so old a man be responsible for myocardial failure?

DR PAUL D WHITE He did have fever on the first admission and leukocytosis on the second.

DR SPRAGUE The temperature was only 100.5°F, and he came in with an obstructing prostate.

Do you believe, Dr White, that we can say that toxemia from infection induces heart failure?

DR WHITE It may if the heart is already diseased. Moreover, this man was old enough to have arteriosclerotic coronary changes, besides the syphilitic aortitis affecting the mouths of the coronaries.

DR SPRAGUE The electrocardiogram is consistent with a digitalis effect. We know he had arcus senilis, but that is all in the way of sclerotic change.

DR WHITE Probably the arrhythmia was not directly responsible for death, although in combination with other factors it may have played something of a role. The last straw was doubtless the pulmonary complication on top of coronary insufficiency, which in turn was largely of syphilitic origin.

Infarcts of lung, multiple  
Benign hypertrophy of prostate  
Cystitis, chronic  
Pyelonephritis, chronic  
Arteriosclerosis

ing to 50, the pulse to 150 and the temperature to 103°F. An electrocardiogram at this time showed an auricular rate of 105 and a ventricular rate of 140. T<sub>1</sub>, T<sub>2</sub> and T<sub>4</sub> were inverted. There were nodal tachycardia and nearly complete A-V dissociation. The patient rapidly failed and died a few hours later, on the fourth hospital day.

#### DIFFERENTIAL DIAGNOSIS

DR HOWARD B SPRAGUE. I am prepared to modify whatever views I may have about the final episode in this case in accordance with what Dr Hampton may be able to tell me about the x-ray films.

On the first admission we have an arteriosclerotic Negro, with positive Hinton and Wassermann tests, who came in with an obstructing prostate. There is no evidence to show that this was a cancer of the prostate, but there may have been some neoplastic disease in it. Our attention here is focussed on the heart and lungs and the renal situation. So far as the heart is concerned we have left ventricular enlargement, an aortic diastolic murmur, a degree of aortic regurgitation which can be measured by the arterial pulse and the low diastolic level, an aortic second sound which is accentuated and tympanic, and an increase in the pulmonary second sound, all of which indicate left ventricular failure and pulmonary hypertension. The first sound was loud instead of diminished, which is rather unusual. So far as etiology is concerned, there does not seem to be adequate reason to suspect hypertensive or rheumatic heart disease. At his age and in the face of the positive blood it would take a good deal of courage to avoid a statistical bias and say this man did not have aortic syphilis. I assume that he had.

He showed signs consistent with fluid in the left pleural cavity. I am not quite clear about this part of the history. Later on we hear that he came back and showed rales at both bases, with evidence of a moderate amount of fluid at the right base. I do not know whether it means in addition to the signs at the left base or that the signs at the left base had, in the meantime, cleared up. If this were an effusion in the left base that cleared up under digitalis and recurred on the right, we might have a different point of view. His renal situation at the time of the first entry was impressively poor. The nonprotein nitrogen was 32 mg per 100 cc, and toward the end it was 45 mg. He showed only a little albumin in the urine. He was sent home at that time on digitalis and for three months kept it up on a ration of 4½ gr a day, which is a good sized

dose and may be responsible for the final disturbance of cardiac rhythm. He had evidence of digitalis toxicity. We have only one x-ray examination and I should like to have Dr Hampton talk about that. It was taken at the first admission.

DR AUBREY O HAMPTON. We have two films. The second was taken primarily for obtaining a lateral view of the chest. There is a large heart, apparently due to left ventricular hypertrophy. The supracardiac shadow is widened without evidence of aneurysm, but the usual curve of the aortic knob is gone. The aorta is dilated in the ascending portion, not enough to make a positive diagnosis of aneurysm or to rule out the possibility of its being due to hypertension.

This process at the left base is quite interesting in view of the fact that it was completely ignored by the surgeons. The X-ray Department was upset about that. We thought it was obvious evidence of longstanding infection in the pleura, in the lateral view, it is quite sharply defined and in all respects corresponds to an encapsulated empyema. Dr Edward D Churchill has pointed out that the ribs in the region of chronic inflammatory disease in the pleura are definitely thickened, and the rib changes in this case make us more certain that the shadow is due to infection. We thought at first that this periosteal thickening always meant pus, but it does not. It can occur with longstanding pleural effusion without pus. So we cannot insist that in this case there is pus in the pleural cavity, but we can be sure that the disease is inflammatory and that the lesion is sharply localized and has the appearance of encapsulated fluid. We also saw this sharply defined area of rarefaction, seen only in the lateral view, at the anterior margin of the lung, which looks like a bleb. Although there is no other evidence of gross emphysema in the chest and although we could interpret this as a pulmonary cyst, the latter are rare and the lesion is probably an emphysematous bleb.

DR SPRAGUE. What is your reaction to the statement about the ribs' being close together?

DR HAMPTON. That means there is retraction on the left side of the chest due to longstanding pleurisy. There is no question that this man had had an infectious process in the pleura for a long time.

DR SPRAGUE. What about the problem of pulmonary collapse on that side?

DR HAMPTON. There is no evidence of collapse of the lung except this area of density, which can be explained by the shadow in the pleura.

DR SPRAGUE. Do you think this is all outside the lung?

DR HAMPTON. Yes.

DR. SPRAGUE Could you say anything about the aorta in the lateral view?

DR. HAMPTON I think it is diffusely dilated. I do not see any aneurysm.

DR. SPRAGUE There would seem to be a definite increase in the first portion of the arch.

DR. HAMPTON It is dilated.

DR. SPRAGUE One might assume, on hearing the discussion, that these findings were present before and after he came back. What was found at the right base was in addition to what he had had at the left base, and was no doubt due to congestive failure. This left basal lesion with its relation to the diagnosis of syphilis is the bothersome thing.

At the time of his final entry there was very severe dyspnea and orthopnea without pain and signs of increasing congestive failure, with a febrile episode at the end which was probably due to a pneumonic process. I am trying to hook this up into one diagnosis, that of a syphilitic process.

You do not see anything in this chest film that makes you think he had any metastatic lesion from the prostate?

DR. HAMPTON No.

DR. SPRAGUE The other findings at the end of his illness are of no help in making a diagnosis.

He was an arteriosclerotic individual who was very ill and who probably had a diffuse syphilitic aortitis. From what evidence we have, it is not possible to say he had an aneurysm of the descending aorta with pulmonary collapse. He may have had some aneurysmal dilatation of the arch or even of the intrapericardial portion of the aorta, and the story certainly suggests progressive narrowing of the coronary ostia. I am unable to connect the signs at the left base with the underlying condition but am unwilling to guess at anything other than a syphilitic process in the pleura. The final cardiac episode with this type of arrhythmia and dissociation can well be explained by the large doses of digitalis.

DR. F. DENNETTE ADAMS How often do you see a syphilitic patient die of congestive failure with no more evidence of valvular damage than this man showed?

DR. SPRAGUE I have to invoke involvement and narrowing of the coronary ostia. With such lesions, syphilitic patients may die with severe dyspnea and congestive failure and without a great deal of peripheral edema.

DR. CHAMBERLAIN LYONS These blebs are not numerous enough to assume that emphysema precipitated cardiac failure?

DR. SPRAGUE One would think in such a case that there would be some evidence of right-sided

strain, such as cor pulmonale, rather than left-sided cardiac hypertrophy.

DR. LYONS Could not prolonged toxemia from suppuration in so old a man be responsible for myocardial failure?

DR. PAUL D. WHITE He did have fever on the first admission and leukocytosis on the second.

DR. SPRAGUE The temperature was only 100.5°F, and he came in with an obstructing prostate.

Do you believe, Dr. White, that we can say that toxemia from infection induces heart failure?

DR. WHITE It may if the heart is already diseased. Moreover, this man was old enough to have arteriosclerotic coronary changes, besides the syphilitic aortitis affecting the mouths of the coronaries.

DR. SPRAGUE The electrocardiogram is consistent with a digitalis effect. We know he had arcus senilis, but that is all in the way of sclerotic change.

DR. WHITE Probably the arrhythmia was not directly responsible for death, although in combination with other factors it may have played something of a role. The last straw was doubtless the pulmonary complication on top of coronary insufficiency, which in turn was largely of syphilitic origin.

## PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY The postmortem revealed very obvious syphilitic heart disease. The aorta showed rather diffuse dilatation, with numerous scattered stellate scars. The coronary mouths appeared to be nearly 1 cm. above the aortic cusps, a finding indicating that the cusps had been drawn down and retracted, as is so common in syphilis. They were not, however, separated as they often are, so that the degree of regurgitation was, I think, a mild one. The mouth of the right coronary was quite markedly narrowed by scar tissue. It showed a few atheromatous plaques but no further narrowing, and the left coronary was free. The heart was moderately hypertrophied. The interesting finding in the autopsy was a large lesion at the base of the left pleural cavity (Fig. 1). It con-

adherent to, but easily separable from, the lung. On section many irregular, yellowish necrotic areas were found scattered through the fibrous tissue. There were no purulent foci, no cavities and no areas of solid calcification, although the tissue seemed slightly gritty on section.

The problem centers around what this mass is. The gross appearance is perfectly consistent with that of a gumma, but the location is an unusual one. Stains for spirochetes are negative. The histology does not in the least suggest tuberculosis. It is possible for an undrained empyema to organize and leave a scar which might be something like this. On the other hand, my personal hunch is that the lesion is probably gumma. I do not know of any way to prove it with certainty.

A PHYSICIAN Are not the empyemas which organized more apt to show calcium?

DR. MALLORY Yes, I should expect more calcium. There was some, but just occasional small gritty particles.

He had, of course, an enlarged prostate and the usual sequelae of that—cystitis, dilated ureters, dilated kidney pelvises on both sides and generalized infection of the urinary tract. The terminal episode in this case was one of pulmonary embolism. He had multiple infarcts throughout both lungs, and there was a choice of numerous sources from which the emboli might have come. There were thrombi in the right auricle and in both popliteal veins and many in the periprostatic plexus, one of which I think probably was the source.

DR. SPRAGUE Do you think we always ought to say pulmonary embolism? I have got tired of saying it in every case, and with this temperature reaction I thought I should take a chance and say pneumonia.

DR. MALLORY In saying pulmonary embolism rather than terminal pneumonia I think one is statistically more apt to be right.

FIGURE 1 Posterior View of the Thoracic Organs

To the left of the aorta is the transected wedge shaped gummatous mass which occupied the lower portion of the left pleural cavity

sisted of a roughly pyramidal mass of fibrous tissue measuring 7 by 5 by 4 cm. It was firmly attached to the lower four thoracic vertebrae and the corresponding ribs but did not penetrate the periosteum and involve the bones. On its medial aspect it was adherent to the aorta, but a plane of cleavage could easily be developed. It was

## CASE 25182

## PRESENTATION OF CASE

A fifty-seven-year-old married commercial agent was admitted complaining of intermittent incontinence, numbness in the extremities and abdominal distention.

At the age of twenty-one years the patient had had gonorrhea and a venereal wart on the prepuce which was "burned" and healed in about two weeks. A urethral stricture developed which was dilated with sounds and apparently cured in about six months. No blood test was done, and he remembered no skin eruption. Until seven years before entry he was well and healthy, and at this time his wife noted that he hesitated in his speech

This apparently did not progress significantly. One and a half years before admission intermittent enuresis developed, but there was no incontinence during the day. Three months before entry this condition became considerably worse and he visited a physician who found "positive serology." Intravenous injections were begun at this time. Three days before admission he noted numbness in both lower extremities, muscle twitchings and beginning ataxia, worse on the right side. He had occasional severe tonic contractions of the calf and thigh muscles, but no pain. During the previous twenty-four hours there was oliguria, and distention of the lower abdomen. He had had no rectal incontinence but recently had noted increasing constipation.

Physical examination showed a moderately obese male in no acute discomfort. The pupils were very small and did not react to light. The mouth was said to be asymmetrical, but there was no noticeable muscular weakness and no further details were recorded. Examination of the heart and lungs was not remarkable. The blood pressure was 140 systolic, 80 diastolic. The abdomen showed generalized distention. The bladder was distended. Rectal examination showed normal sphincter tone. The Romberg test was positive. There was moderate ataxia. Pain and temperature sensations were diminished over both lower extremities. There was almost complete absence of vibratory sense. The abdominal reflexes were absent except in the left hypochondrium. Babinski signs were positive bilaterally. The finger-to-nose and heel-to-shin tests were poor.

The temperature was 98.2°F, the pulse 82, and the respirations 22.

The urine examination was negative. The blood showed a red-cell count of 4,780,000 with 85 per cent hemoglobin, and a white-cell count of 8800 with 71 per cent polymorphonuclears. A blood Hinton test was positive. A blood smear showed malarial parasites. A lumbar puncture showed an initial pressure of 150 mm of water and normal dynamics. The spinal fluid showed 2 lymphocytes per cubic millimeter and a total protein of 67 mg per 100 cc. A goldsol curve was 5555532100. A spinal-fluid Wassermann test was strongly positive.

On the second day after entry the patient was inoculated with malarial organisms. During the first week in the hospital the patient's abdominal distention increased and there was increasing discomfort. Examination showed generalized abdominal distention, and the cecum was thought to be especially dilated. There was no tenderness, spasm or audible peristalsis. An x-ray of the abdomen at this time showed that the right half of the colon was filled with gas

and markedly dilated. The cecum was huge. The small intestine also contained gas and was dilated. On the following day the abdominal pain had increased in severity and the patient vomited foul-smelling material several times. Distention became more marked, the pulse rose to 110, and the patient perspired freely. The temperature, which had not been above 99°F during the preceding eight days, rose to 100°F. Shortly thereafter a laparotomy was performed.

He died on the second postoperative day, and during the last two days his respirations rose from 20 to 35.

#### DIFFERENTIAL DIAGNOSIS

DR. OLIVER COPE. I should like to discuss the differential diagnosis before we turn to the x-ray films, because I suspect that the latter may be helpful in making the diagnosis.

DR. TRACY B. MALLORY. The films have been lost, so you need not be afraid of their giving away the diagnosis.

DR. COPE. Then I should like to recall an incident which occurred during the study of another patient seen here recently. This patient had the disease from which I suspect the patient under discussion suffered. The surgeons, among them myself, and members of the X-ray Department were struggling to make a diagnosis. The x-ray films were spread out on the illuminator. At this moment Dr. Holmes walked by, glanced at them casually and said, "H'm, neurosyphilis, I see," and passed on into his office. That is why I thought it would be better to wait until after my discussion before we allowed Dr. Holmes to look at the films.

I think the diagnosis lies between a "cord colon" and true mechanical obstruction of the large bowel. It is obvious that the man had neurosyphilis and, with it, involvement of the spinal cord. Whether the recent malarial therapy had anything to do with the symptoms when he entered the hospital and those for which he was operated on, it is difficult to tell. It is certain from the history that he had a distended "cord bladder," with enuresis. The disease had recently been progressive, and it is significant that the first intestinal symptoms appeared when the bladder symptoms were becoming more pronounced.

I am not going to try to discuss the various lesions in the colon which, through production of mechanical obstruction, might enter into the differential diagnosis. I want to weigh mechanical obstruction, on the one hand, against the type of dilated colon seen in central-nervous-system syphilis, on the other. In favor of paresis or central-nervous-system syphilis as the origin of

the symptoms in this patient is the fact that we know this disease was already present and that it had already produced a cord bladder. Whether the recent exacerbation of bladder symptoms, together with the onset of symptoms from dilatation of the colon, was due to spreading disease in the cord from malarial treatment, I cannot tell, and I am not competent to discuss it. Also in favor of the tabetic colon is the observation that the first abdominal distention occurred without any symptoms other than constipation. It is true that he had some discomfort later on, but this he might have had from abdominal distention rather than from intestinal dilatation. If there had been a primary mechanical obstruction I should have expected intermittent pain. Of course the lack of sensation may have been due to injury in the cord, since we know that there was loss of sensation in the extremities. In other words he might have had true mechanical obstruction, and pain was absent because of the nerve lesion. The examination of the abdomen is also in favor of the diagnosis of cord colon. The absence of audible peristalsis, of tenderness and of spasm is noted, and we should expect one or all these findings with this degree of dilatation had it been due to pure mechanical obstruction. In the cord colon, peristalsis is not audible because feces in the cecum and right colon are usually semi-solid and there is not the swish and rush of fluid content encountered in mechanical obstruction.

The diagnosis of cord colon does not necessarily explain the fecal vomiting which the patient had terminally, and also does not take into account, so far as my own experience is concerned, the dilatation of the small bowel. I do not know, however, why dilatation of the small bowel cannot occur just as well as dilatation of the large intestine, since the nerve lesions which lead to dilatation of the latter would also be present in the levels involving the former. The fecal vomiting is not explained unless we assume the obstruction had come to such a point that there was an actual backing up of contents of the small intestine into the stomach. In other words, the nerve lesion and consequent functional disability had resulted in a virtual mechanical obstruction due to fecal impaction, and the fecal vomiting was secondary to that. It is my inclination to put the picture together in that way.

As to the final contributing cause of death, we are not told what the operation was. From the record as given the only thing we have as a clue is the rise in respirations to 35. That could have been due, of course, to a postoperative pulmonary complication, or to encroachment on the vital capacity in the chest due to increasing abdominal distention. Another possibility, which undoubtedly

entered to some extent into the immediate cause of death, was the electrolyte imbalance subsequent to the intestinal obstruction and vomiting. A third possibility is peritonitis subsequent to operation, and increasing distention.

In conclusion, I am therefore forced to make a diagnosis of syphilitic paresis with cord paralysis, a cord bladder and a cord colon, if I may coin the expression. With extensive dilatation of the colon there occurred electrolyte loss from vomiting, and possibly pneumonia and peritonitis, as contributing causes of death.

DR. MALLORY: The operation was simply a cecostomy.

DR. COPE: That would not change my diagnosis.

DR. HARRY C. SOLOMON: I think the first thing to comment on is the correct and very clever diagnosis as regards the colon. I might add that it is very uncommon to get a tremendously bloated colon of this sort in any of the syphilitic diseases of the spinal cord.

There are one or two omissions in the history. This man, when I first saw him, had been under the care of a physician who had treated him for two or three months prior to his coming to this hospital. Just prior to admission he had had a sudden onset of what was said to be ataxia. He became suddenly incapable of walking, and within twenty-four hours he was admitted. Before this he had been receiving tryparsamide, and the question arose whether there was any relation between the drug and the sudden collapse of the lower extremities, whether treatment had caused a Herxheimer reaction or some degeneration of the spinal cord. He was given malarial treatment on his arrival.

I take a good deal of exception to the diagnosis of general paresis. Clinically this man showed no symptoms of cerebral involvement. Before a diagnosis of general paresis, which is by ordinary definition a psychosis, is definitely established, there has to be evidence of mental changes. This man had a positive goldsol curve which is common enough in cord disorders as well as characteristic of general paresis. Our examination, aside from the pupils, which so commonly show abnormalities in cord syphilis, showed no evidence of lesions in the cerebrum, and the problem seemed to be merely that of a cord lesion. He had something that suggested a transverse lesion. Furthermore, he had symptoms characteristic of disorders of the lateral and posterior columns—a loss of vibratory sense and urinary difficulty.

It was after malarial treatment had been started that his colon began to blow up quite progressively and fairly rapidly. Stupes, enemas, rectal tubes and the like had no effect on the situation. There

fore Dr E Parker Hayden was asked to come in and see him as regards operative procedure. The x-ray films, as indicated, were very characteristic of an ileus, just dilated bowel without any evidence of obstruction. Dr Hayden opened the colon and drew off a good deal of gas, a procedure which gave the patient quite a bit of temporary relief. He immediately began to blow up again in the same fashion, and he succumbed to what seemed to be a bronchopneumonia.

DR GEORGE W HOLMES. This patient had only one film taken and that showed the gas-distended colon. The films which I am putting up now come from another very similar case, the one to which Dr Cope referred at the beginning of his discussion. The first thing that one notices is the prominent aorta. That would naturally lead you to suspect that the patient had syphilis but is not enough to make that diagnosis. It is a well-known fact that in a certain number of patients with neurosyphilis we do get a relaxed and dilated colon. Dr James R Langley examined a number of cases at the McLean Hospital and found in a high percentage an enormously dilated colon. Of course the appearance in this film could be due to obstruction, but at the time I saw it, an enema had been given and we knew there was no obstruction in the colon. This emphasizes the danger, in cases of dilated large bowel, of accepting a diagnosis made from plain films alone. The surgeons have objected to our giving a barium enema in this type of case, and I think they are justified, because it interferes with the operation, but unless we do it we can never be certain whether there is obstruction or only a relaxed dilated bowel. The points, then, of interest in this case are first, the dilated colon which was proved by barium enema not to be due to obstruction, and second, the prominence of the aorta.

DR SOLOMON. The malarial treatment was given as a last desperate attempt, in the case of the sudden onset of symptoms suggesting transverse myelitis, such as this man showed, one has no assurance that anything else is going to give relief.

Myelitis

#### PATHOLOGICAL DISCUSSION

DR MALLORY. At operation an enormously distended cecum was found. It was so large it was almost impossible to manipulate. It was necessary to put in a needle and withdraw a considerable amount of gas before a cecostomy could be done. That drained the gas from a limited portion of the ascending colon but not from the distended descending colon on the left side. He proceeded downhill with renewed and progressive dilatation of the intestines. At the time of autopsy the entire small bowel was markedly dilated and the large bowel looked as if it had never been decompressed. The rest of the autopsy showed nothing that could be considered as the cause of death. The lungs showed diffuse collapse, undoubtedly due to the high diaphragm, and marked congestion and edema, which might be interpreted as evidence of shock. There was no significant amount of pneumonia. The examination of the spinal cord did show a localized lesion in the thoracic portion. I shall ask Dr Kubik to describe it.

DR CHARLES S KUBIK. The arachnoid of the entire thoracic cord was pearly gray in color, and opaque. There were fibrinous adhesions in the subarachnoid space, and the cord in the mid-thoracic region was softer than normal. A careful search did not reveal evidence of thrombosis in any of the visible spinal arteries. Microscopic sections of the spinal cord, brain stem and brain showed a slight to moderate lymphocytic exudate, perivascular infiltration with lymphocytes and plasma cells, and varying degrees of endarteritis. There was a thinning out of nerve fibers along the periphery of the cord. In the upper third of the thoracic cord on the right side was a large focus of degeneration involving the posterior half of the lateral column and extending a short distance into the posterior column. The degeneration was not complete. Although the myelin was completely destroyed, many of the axis cylinders were preserved. This had the appearance of a vascular lesion and was unquestionably responsible for the myelitic symptoms.

The case provides a fairly good example of meningovascular neurosyphilis.

DR JOHN D STEWART. The stomach was not dilated?

DR MALLORY. Not particularly.

DR J H MEANS. I should like to ask if any attempts were made to deflate him by Dr Jacob Fine's method of oxygen inhalation.

DR MALLORY. That apparently was not tried, nor was spinal anesthesia.

the symptoms in this patient is the fact that we know this disease was already present and that it had already produced a cord bladder. Whether the recent exacerbation of bladder symptoms, together with the onset of symptoms from dilatation of the colon, was due to spreading disease in the cord from malarial treatment, I cannot tell, and I am not competent to discuss it. Also in favor of the tabetic colon is the observation that the first abdominal distention occurred without any symptoms other than constipation. It is true that he had some discomfort later on, but this he might have had from abdominal distention rather than from intestinal dilatation. If there had been a primary mechanical obstruction I should have expected intermittent pain. Of course the lack of sensation may have been due to injury in the cord, since we know that there was loss of sensation in the extremities. In other words he might have had true mechanical obstruction, and pain was absent because of the nerve lesion. The examination of the abdomen is also in favor of the diagnosis of cord colon. The absence of audible peristalsis, of tenderness and of spasm is noted, and we should expect one or all these findings with this degree of dilatation had it been due to pure mechanical obstruction. In the cord colon, peristalsis is not audible because feces in the cecum and right colon are usually semi-solid and there is not the swish and rush of fluid content encountered in mechanical obstruction.

The diagnosis of cord colon does not necessarily explain the fecal vomiting which the patient had terminally, and also does not take into account, so far as my own experience is concerned, the dilatation of the small bowel. I do not know, however, why dilatation of the small bowel cannot occur just as well as dilatation of the large intestine, since the nerve lesions which lead to dilatation of the latter would also be present in the levels involving the former. The fecal vomiting is not explained unless we assume the obstruction had come to such a point that there was an actual backing up of contents of the small intestine into the stomach. In other words, the nerve lesion and consequent functional disability had resulted in a virtual mechanical obstruction due to fecal impaction, and the fecal vomiting was secondary to that. It is my inclination to put the picture together in that way.

As to the final contributing cause of death, we are not told what the operation was. From the record as given the only thing we have as a clue is the rise in respirations to 35. That could have been due, of course, to a postoperative pulmonary complication, or to encroachment on the vital capacity in the chest due to increasing abdominal distention. Another possibility, which undoubtedly

entered to some extent into the immediate cause of death, was the electrolyte imbalance subsequent to the intestinal obstruction and vomiting. A third possibility is peritonitis subsequent to operation, and increasing distention.

In conclusion, I am therefore forced to make a diagnosis of syphilitic paresis with cord paralysis, a cord bladder and a cord colon, if I may coin the expression. With extensive dilatation of the colon there occurred electrolyte loss from vomiting, and possibly pneumonia and peritonitis, as contributing causes of death.

DR. MALLORY: The operation was simply a cecostomy.

DR. COPE: That would not change my diagnosis.

DR. HARRY C. SOLOMON: I think the first thing to comment on is the correct and very clever diagnosis as regards the colon. I might add that it is very uncommon to get a tremendously bloated colon of this sort in any of the syphilitic diseases of the spinal cord.

There are one or two omissions in the history. This man, when I first saw him, had been under the care of a physician who had treated him for two or three months prior to his coming to this hospital. Just prior to admission he had had a sudden onset of what was said to be ataxia. He became suddenly incapable of walking, and within twenty-four hours he was admitted. Before this he had been receiving tryparsamide, and the question arose whether there was any relation between the drug and the sudden collapse of the lower extremities, whether treatment had caused a Herxheimer reaction or some degeneration of the spinal cord. He was given malarial treatment on his arrival.

I take a good deal of exception to the diagnosis of general paresis. Clinically this man showed no symptoms of cerebral involvement. Before a diagnosis of general paresis, which is by ordinary definition a psychosis, is definitely established, there has to be evidence of mental changes. This man had a positive goldsol curve which is common enough in cord disorders as well as characteristic of general paresis. Our examination, aside from the pupils, which so commonly show abnormalities in cord syphilis, showed no evidence of lesions in the cerebrum, and the problem seemed to be merely that of a cord lesion. He had something that suggested a transverse lesion. Furthermore, he had symptoms characteristic of disorders of the lateral and posterior columns—a loss of vibratory sense and urinary difficulty.

It was after malarial treatment had been started that his colon began to blow up quite progressively and fairly rapidly. Stupes, enemas, rectal tubes and the like had no effect on the situation. There

board members or even the courts in arriving at just decisions. In this field, as it is sometimes in general practice, the first visit to and the eventual treatment of a patient may determine success or failure in dealing with a given case.

With these underlying premises the contention of this speaker that medical societies should include industrial medicine in their programs for post graduate instruction is sound. He stated that for the physician's protection as well as that of the patient the inexperienced doctor should prepare himself for dealing with cases coming under the operation of the workmen's compensation acts or refrain from carrying on this practice. Anyone may have to respond in an emergency and render first aid, but properly qualified surgeons are rarely more than thirty minutes away from a given locality in Massachusetts and should be called. The Workmen's Compensation Act is a contribution to the welfare of those working people who come within the scope of the provisions defined in the act, and should have the support of the medical profession.

The Council of the Massachusetts Medical Society at its last meeting voted that the President appoint a committee to study the problems of industrial health. If this committee should recommend inclusion of a broad public-health educational program in the postgraduate instruction courses now in operation, it might well include some of the phases of the service now carried on under the Workmen's Compensation Act.

## DRINKING AND TRAFFIC ACCIDENTS

THE toll of traffic accidents has forced upon us the problem of the 'accident-repeater' and also that of the driver under the influence of alcohol. The last report<sup>1</sup> of the Committee on Tests for Intoxication, made to the National Safety Council, brings out two important points: half the drivers killed in automobile accidents had been drinking and one third the pedestrians killed had been drinking.

The effect of alcohol in impairing judgment and mechanical ability is too well known to need

comment. The report states that the average driver with a blood-alcohol concentration of 0.15 per cent or more is fifty-five times as liable to have a personal-injury accident as is one without alcohol. While there are minor variations in the response of different persons to alcohol, in general the commonly accepted evidences of intoxication have paralleled the alcohol concentrations in the blood and tissues.

In Evanston, Illinois, a study by Holcomb<sup>2</sup> showed that 12 per cent of 1750 non-accident drivers stopped and tested had been drinking, whereas 47 per cent of the accident drivers had been drinking. He also found that from midnight to six in the morning was the most dangerous period on the road from the standpoint of drunken driving, inasmuch as over 40 per cent of all drivers tested during that period had been drinking.

After thorough tests of various procedures for examining drivers involved in accidents for evidence of alcohol, the committee advises the use of special report forms, chemical tests for the presence of alcohol in breath, blood or urine, and medical examination to prevent the confusion of illness or injury with alcoholism. Only by the accurate determination of the degree of alcoholism and by the prompt and sure punishment of the drinking driver can this menace be curbed.

## INDUSTRIAL MEDICINE

WHENEVER the adequacy of medical care in any field is under discussion the attention of the profession is directed to the problems involved. If sociologic, public-health and economic questions are included in the program the appeal for consideration has especial merit. Industrial medicine includes all these three subjects, and imposes on the doctor practicing under the provisions of any workmen's compensation act a range of responsibilities which were brought to the attention of the first annual Congress on Industrial Health held in Chicago, January 9. There were in attendance more than two hundred prominent industrial medical practitioners and representatives of insurance and industry.

Massachusetts, which has been given a prominent position among her sister states because of

her striking contributions to the welfare of all classes, passed a law, which became effective in 1912, providing for workmen's compensation. Only two states—Arkansas and Mississippi—have failed to enact workmen's compensation laws, and the legislature of the former is now considering a bill related thereto. The act in Massachusetts has been amended from time to time and now protects the injured workman, his employee and the insurance company, so far as possible with justice to each interest. The provisions of this statute cover, besides surgical care and operations, medical conditions to which the workman may be liable, such as sunstroke, hernia, heart trouble, tuberculosis, pneumonia, incapacity caused by exposure to granite dust and other situations in which it can be shown that the employer may not have exercised due care in protecting the employee from deleterious influences.

Both the insurance companies and employers are co-operating in eliminating conditions in industrial plants which are inimical to the well-being of the workers, but even so the administration of the statutes is a complicated procedure involving repeated hearings and, not infrequently, resort to reviews by superior and supreme courts. Hence, in so far as the doctor is brought into a case his responsibilities extend beyond the care of the patient.

Insurance companies have given generous commendation of the medical work done by physicians in connection with service to injured workmen, but have stated that the quality is highest in the cities and large towns.

This led one of the speakers\* before the Congress to point out that medical schools do not or cannot properly prepare students to fill the present requirements involved in the practice of industrial medicine, with the result that doctors in small communities may be quite deficient in experience and training, in the first instance, to meet the exacting conditions often encountered in dealing with the patient and, later, to keep records and to construct reports that help the industrial accident-

### BLEEDING IN THE PUERPERIUM

Mrs. M. G., a twenty-five-year-old primipara, at term, was admitted to the hospital at 8 a. m. on September 17, 1932 in mild labor. The membranes had ruptured.

\*A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

The family history was irrelevant. The patient had had no childhood diseases, but she had undergone an appendectomy at nine years of age. Catamenia began at twelve, were regular with a twenty-eight-day cycle and lasted four days. Her last period was December 10, 1931, making her due for delivery September 17. The prenatal period had been entirely normal.

Examination one hour after admission showed the head well engaged in the LOA position, there was no dilatation of the cervix. Contractions were occurring at six- to eight-minute intervals.

Under Sodium Amytal analgesia the patient progressed slowly to full dilatation at 3.30 a. m. the following morning. Under nitrous oxide and oxygen anesthesia an 8 lb., 5 oz. baby was delivered by low forceps at 4.30 a. m. There was a small vestibular tear, in which two stitches were placed, but no perineal laceration. The placenta separated in fifteen minutes and was expressed by the method of Credé. As the placenta was being delivered, the patient came out of anesthesia and moved violently, resulting in some tearing of the placenta as it was removed from the vagina. The placenta was pieced together after delivery and appeared to be complete. As there was no abnormal bleeding and the fundus contracted well, exploration of the interior of the uterus seemed contraindicated.

The temperature remained normal until the evening of the third day when it rose to 101°F, the pads were slightly foul, and there was some tenderness in the left lower abdomen. The temperature remained elevated for three days, reaching a maximum of 102°F, then dropped to normal on the morning of the eighth day and remained normal until the evening of the tenth day. The lochia during this time had a foul odor but was serous in character. Treatment had been limited to ice applied to the lower abdomen and elevation of the head of the bed. On the evening of the tenth day the patient passed two large blood clots, and almost simultaneously the temperature rose to 103°F. One half drachm of fluid extract of ergot, every four hours, was prescribed. The patient continued to flow freely but not alarmingly. The temperature remained between 103 and 104.5°F, and the pulse rose gradually to 120 but was of good quality. One cubic centimeter of posterior pituitary extract was given hypodermically every four hours. On the eleventh day the patient had a severe chill. On the morning of the twelfth day the bleeding had become alarming in amount and the pulse had risen to 130 and had become definitely weaker. The temperature was 104.5°F. The white-blood-cell count was 10,350, and the red blood-cell count 2,420,000. A differential count

showed 75 per cent polymorphonuclears, 15 per cent lymphocytes, 4 per cent large mononuclears and 8 per cent miscellaneous cells. It was evident that active intervention must be taken despite the temperature.

Under light nitrous oxide and oxygen anesthesia the uterus was quickly but lightly curetted, and a moderate-sized piece of placental tissue and some additional debris were removed. The uterus was swabbed with 7 per cent tincture of iodine and tightly packed with sterile gauze. Two cubic centimeters of posterior pituitary extract was given intramuscularly, followed by 1 cc every four hours. Ice to the fundus was continued. Due partly to lack of co-operation on the part of the patient's family, a satisfactory transfusion donor could not be obtained.

In spite of the measures taken, the patient continued to ooze through the pack. Five cubic centimeters of hemostatic serum (La Penta) was given intramuscularly. The flow then diminished and gradually became brownish in color but still had a foul odor. The pack was removed forty-eight hours after the curettage, without further bleeding. The temperature continued to range from 98.4°F in the morning to 103 or 104°F in the afternoon. The vaginal discharge was scanty and serous in appearance, with a foul odor. Non-specific protein therapy in the form of 10 cc of sterile milk intramuscularly daily for five doses was tried with no effect on the temperature. The patient developed an abscess over the right deltoid muscle, probably resulting from an infected hypodermic-needle puncture, which was opened on the twenty-second day with no effect on the temperature. Repeated pelvic examinations were negative, as were blood cultures. About the twenty-third postpartum day a slight but progressive drop in both morning and evening temperatures began without additional therapy, and on the twenty-sixth day a sudden drop to normal occurred. The temperature thereafter remained normal, and the patient was discharged on the thirty-seventh postpartum day.

*Comment.* It is always difficult, no matter how carefully a placenta is examined, to be certain that it is intact. So often it appears ragged as though a piece were lacking that, unless bleeding occurs after the birth of the placenta, only rarely does one think of entering the uterus because of a piece that may be retained. Furthermore, such pieces of placenta are often spontaneously extruded without any accompanying hemorrhage.

The temperature which this patient ran after the third day of her convalescence was undoubtedly due to a saprophytic infection. The treatment

of these cases when not associated with hemorrhage is always conservative. Ice to the fundus, a modified Fowler's position and oxytocics are almost always sufficient. When this patient began to bleed on the twelfth day, it was evident, in spite of her temperature, that the uterus contained retained tissue. Hemorrhage is the only indication for entering the uterus after delivery, and this is true even in the presence of sepsis. The more conservatively the uterus is explored the better it is for the patient. The pieces may often be removed with the fingers or by ovum forceps, but if a curet must be used, it should not be a sharp one and the operation cannot be done too delicately. It is surprising how little placental material may be obtained, it takes but a small piece to cause very free bleeding. Packing of the uterus after it has been explored in the presence of bleeding is an essential part of the performance. This pack is used to control further immediate bleeding and also acts as an irritant whereby other fragments of placenta may be loosened.

The use of LaPenta hemostatic serum, while apparently of value in this case, is not in general use. Transfusion at the time when the red count was 2,420,000 would certainly have been valuable.

While the placenta which caused this bleeding may have abetted the infection, it was not per se the cause of the infection. Cultures of the lochia might have been valuable for the establishment of specific treatment.

It should be borne in mind that every case, whether septic or not, which bleeds profusely after the first few hours after delivery is always associated with an intrauterine lesion. This may be a placental polyp or a true accreta, most frequently it is a piece of retained placenta. The symptom demands intrauterine exploration and, oftentimes, transfusion.

#### LEGISLATIVE NOTES

Below is listed the progress in the Legislature of some of the bills in which the Massachusetts Medical Society is interested.

##### FAVOR

**S 25b** Bill relative to the meaning of the terms rendering medical service, practice of medicine and holding oneself out as a practitioner of medicine and to exempt dentists, optometrists and chiropodists in certain cases from penalties provided for the unlawful practice of medicine. The bill was proposed by the Board of Registration in Medicine. It is favored by the Society with the addition of the following sentence at the end of Section 5A: "Such treatment shall include examination of any secretion, excretion or discharge of the living body."

This bill has been given leave to withdraw.

**H 59** Identical with S 25b.

This bill has been given leave to withdraw.

**H 60** Bill requiring annual licensing of qualified physicians.

With certain changes this bill has been favorably reported by the Committee on Public Health and given to the Committee on Ways and Means.

**H 72** Bill providing for the care of certain infants prematurely born. It was proposed by the Department of Public Health, and corrects defects in the previous bill.

This bill was amended to H 2080 and has been passed to be engrossed.

**H 73** Bill providing for supplementary reporting of congenital deformities and birth injuries in infants. The bill was proposed by the Department of Public Health and requires that supplementary reports be sent to this department.

It has been passed to be engrossed.

**H 74** Bill requiring the clerk or registrar in each city or town to give to persons who file notice of intention of marriage suitable information concerning gonorrhea and syphilis. The bill was proposed by the Department of Public Health and it contains no compulsion.

A report of no legislation necessary has been accepted in the House.

**H 75** Bill making various changes in the laws relating to foods and drugs. The bill was proposed by the Department of Public Health in order to bring the state law into line with the new federal act.

It was heard by the Committee on Public Health on April 13.

**H 287** (revised) Bill providing for a marriage protection law by requiring a physician's examination and certificate before issuance of marriage licenses. This bill was proposed by Rep. Cutler and in its revised form is now favored by your committee.

It was heard before the Committee on Public Health on March 28.

**H 670** Bill providing for the issuance of certificates of approval of bacteriological laboratories by the Department of Public Health. The bill was proposed by the Massachusetts Public Health Association and is similar to the one favored by the Massachusetts Medical Society last year.

This bill was reported favorably by the Committee on Public Health and sent to the Committee on Ways and Means.

**H 852** Bill requiring licensing of hospitals, convalescent homes and nursing homes. This bill was proposed by the Massachusetts Central Health Council and provides for the Department of Public Health to set up certain standards of health and enforce them.

This bill has been favorably reported by the Committee on Public Health and referred to the Committee on Ways and Means.

**H 1407** Bill prohibiting aliens from practicing medicine. This bill was proposed by Rep. Vaughan and is poorly written. It provides that no license be granted to an alien until his first papers have been filed but allows certain very broad exceptions.

This bill was heard by the Committee on Public Health on March 14. An amended bill has been presented.

## OPPOSE

*H 551* Bill requiring that notices of intention of marriage shall be accompanied by a physician's certificate that neither party is infected with syphilis. This bill was proposed by Dr. William Frankman and also needs major revision before being satisfactory.

A report of leave to withdraw has been filed in the House.

*H 758* Bill providing authority to the Board of Registration of Nurses to limit further training of nurses of all classes and attendants under certain conditions. The bill was proposed by Miss Josephine E. Thurlow but is against public policy.

It was heard by the Committee on Public Health on February 2 and again on March 7.

*H 759* Bill providing for training and licensing of first class bedside nurses. This bill was proposed by Miss Josephine E. Thurlow, but is against public policy.

It was heard by the Committee on Public Health on February 2 and again on March 7.

*H 858* Bill regulating the practice of nursing. This bill was proposed by the Massachusetts State Nurses Association, and while it is better than last year's bill, some of last year's defects are still present.

It was heard by the Committee on Public Health on February 2 and again on March 7.

*H 985* Bill requiring doctors of medicine and doctors of osteopathy on the Board of Registration in Medicine. This bill was proposed by the Massachusetts Osteopathic Association and would put two osteopathic physicians on the Board.

This bill has been given leave to withdraw.

*H 986* Bill providing for a doctor of medicine and a doctor of osteopathy on the Approving Authority and the status of approvals by the American Medical Association and the American Osteopathic Association. This bill was proposed by the Massachusetts Osteopathic Association, it weakens the Approving Authority.

This bill has been given leave to withdraw.

*H 1401* Bill providing that certificates of vaccination or non vaccination shall no longer be required as a prerequisite to the attendance of any child in public schools. This is a typical anti vaccination bill.

This bill has been given leave to withdraw.

*H 1898* Bill providing for the establishment and administration of a system of health insurance. This bill was proposed by the State Industrial Council of the Congress of Industrial Organization (CIO) and means complete state insurance medicine with a 4½ per cent pay roll tax. It represents real regimentation of physicians.

This bill has been given leave to withdraw.

CHARLES C. LUND, *Chairman*  
Committee on State and  
National Legislation.

## DEATHS

McCREA—ALBERT J. McCREA, M.D., of 284 Main Street, Southbridge, died April 28. He was in his sixty-ninth year.

Born in Winchendon, he received his degree from the Eclectic Medical College, Cincinnati, Ohio, in 1894. Dr.

McCrea was a director of the Masonic Hospital in Shrewsbury.

He was a member of the Massachusetts Medical Society, the American Medical Association and the Medical Examiners' Association.

His widow, a son and a sister survive him.

SCHORER—CORNELIA B. J. SCHORER, M.D., of Foxboro, died in Berlin, Germany, January 9.

Dr. Schorer received her degree from the Universität Zurich Medizinische Fakultät, Switzerland, in 1897. Before her retirement in 1933 she was a member of the resident medical staff of the Foxborough State Hospital.

She was a fellow of the Massachusetts Medical Society and the American Medical Association and was a member of the American Psychiatric Association and the New England Society of Psychiatry.

WILLIS—JOHN E. WILLIS, M.D., of Worcester, died April 21. He was in his sixty-fifth year.

Born in East Bridgewater, he received his degree from Boston University School of Medicine in 1898. After practicing in Somersworth, New Hampshire, for one year he attended the New York University College of Medicine, studying electrotherapy. In recent years he had continued studies in this specialty at Boston University. In 1903 he went to Worcester and shortly afterward became associated with the Hahnemann Hospital, where he was a staff physician at the time of his death.

Dr. Willis was a fellow of the Massachusetts Medical Society and the American Medical Association and was a member of the American Institute of Homeopathy and the Massachusetts Homeopathic Society.

His widow, a sister and two brothers survive him.

## MISCELLANY

## THE CYTOLOGY OF SPUTUM

When the practitioner sends a sputum specimen to the laboratory he expects usually to learn only whether or not tubercle bacilli are present. Much more can be learned by a careful study of the sputum, as Dr. S. Roodhouse Gloyne, pathologist at the London Chest Hospital, whose work has attracted widespread attention, has shown in the following article, which was prepared especially for *Tuberculosis Abstracts* and appeared in the May issue.

We are all apt to assume that everything that goes into a sputum cup is sputum. Saliva, postnasal and pharyngeal secretions which have trickled down the throat, even gastric contents resulting from retching may be confused with true sputum. The word will be taken here to mean the material which coughing ejects from the respiratory passages. Cytological examination often enables us to determine from what part of the respiratory tract the secretion comes and what its nature is.

Specimens should be as fresh as possible, because cells degenerate more quickly than do bacteria and a stale specimen is valueless for cytological purposes. The next thing is to select suitable portions for examination. There is only one safe rule, namely to select every portion which looks different in appearance from any other portion—mucoid, purulent, pigmented, blood stained, gelatinous, and so forth. The purulent portion is the least useful. The specimen may be poured into a wide dish (an ordinary bacteriological Petri dish) and placed on a light or dark background as required. It is not enough to take a

wild plunge at an evil smelling specimen with a platinum loop and to trust to luck. Each portion should be picked out with sterile forceps, and placed upon one end of a slide. A thin film is then made with the edge of another slide in the same way that one spreads a blood film for malaria parasites. In selecting the portions it is a good plan to go over the specimen carefully first with a hand lens. The technic used by the writer for staining films is a modification of that of Dudgeon and Wrigley (1) fix wet films in Schaudinn's solution (absolute alcohol, 1 part, saturated aqueous solution of mercury bichloride, 2 parts, with 3 per cent acetic acid added immediately before use) for five minutes, (2) pour off fixative and cover with 0.5 per cent iodine in 70 per cent alcohol for two or three minutes, (3) drain off this solution and cover with the following solution for two or three minutes sodium thiosulfate, 7.5 gm., 96 per cent alcohol, 100 cc., distilled water, 450 cc., (4) wash and stain with undiluted Delafield's hematoxylin for two or three minutes, (5) pour off stain and differentiate with 10 per cent hydrochloric acid (6) counterstain with Biebrich's scarlet or orange G, (7) dehydrate with absolute alcohol, clear with xylol and mount in neutral balsam.

The cells encountered may be classified into three groups cells which have migrated from the blood stream, tissue cells from various portions of the respiratory tract, abnormal cells resulting from various types of growth.

The cells of the first group are leukocytes and erythrocytes, and they are found in practically all sputums. The neutrophil polymorphonuclear cell is an essential part of the tissue response in all suppurative diseases of the lung. It is fundamentally a phagocyte and frequently contains organisms. After Lipiodol administration it will show engulfed oil droplets also. The predominance of the lymphocyte, which is such a useful diagnostic sign of tuberculosis in other exudates, is in the writer's view quite valueless in sputum. Lastly there is the eosinophil cell, commonly found in asthma.

Of the tissue cells, the commonest is the transitional squamous cell which covers the anterior surface of the epiglottis, the upper half of the posterior surface, the aryo-epiglottic folds and vocal cords and the pharynx. This cell is generally found in association with large numbers of the organisms of the catarrhal infections. A cytologic picture of this kind is common in the chronic catarrhs of the winter months. The ciliated columnar cell of the epithelium of the respiratory tract extends from the trachea down to the small bronchi and may desquamate and appear in the sputum when the mucosa is ulcerated. It is often seen after the passage of a bronchoscope. The lining cells of the respiratory bronchioles and alveolar ducts are of a low cuboidal non-ciliated type, and they are not easy to distinguish from other mononuclear cells in sputum unless they are adhering together in plaques. *None of the cells in this group are phagocytes.* There is, however, a cell, conveniently considered here, which does phagocytose, namely the macrophage. It masquerades under many names, the heart failure cell, the dust cell, and so forth, but is really part of the reticulo-endothelial system and is an expert phagocyte. It is found in pulmonary tuberculosis, the pneumoconioses, chronic congestive failure and pulmonary edema, and may contain tubercle bacilli, carbon pigment, red-blood cells or hemoglobin pigment, as the case may be. The refractile particles of quartz or asbestos found in the pneumoconioses cannot be seen in the ordinary stained specimen.

With regard to the third group, excluding the hepatic cells of ruptured liver abscess and the lymphadenoma cell of Hodgkin's disease, which the writer has seen in sputum on only one or two occasions, the cells of this group

are neoplastic. In the case of secondary growths of the lung, any form of cell which is found in the primary growth may, of course, appear in the sputum, but in the primary malignant growths of the lung the cells for practical purposes arise from only two kinds of tumor, the oat-cell carcinoma and the squamous carcinoma. The oat-cell carcinoma is generally associated with a primary massive growth of the mediastinal nodes, and although this growth exerts great pressure on the main bronchi, it does not as a rule ulcerate and break down. The oat-cell, therefore, is not commonly found in sputum. Moreover, it is difficult to differentiate from granulation tissue cells and fibroblasts from the bronchial wall. This cell, therefore, should be diagnosed with the very greatest circumspection.

The squamous carcinoma cell is derived from bronchial growths. It is not sufficiently realized that bronchial carcinoma breaks down into cavity with even greater regularity than a tuberculous lesion. A single pulmonary abscess developing insidiously in a person of middle age without obvious cause is more likely than not to be due to a breaking down of a bronchial carcinoma. This cell can be found readily in the sputum but must be carefully distinguished from the normal transitional squamous cell of the upper respiratory tract. It is usually found adhering to its neighbors in small plaques, the individual cells of which exhibit marked diversity of form and size. In the early stage of its growth the cell shows a rounded nucleus with an open chromatin network, a large nucleolus, and a more or less clear cytoplasm with a cell envelope attached to its neighboring cell along the contiguous border, and prickle-cell arrangement. As the cell develops, vacuolation takes place and the nucleus is pushed to one side until it eventually comes to occupy a position near the cell envelope and is squeezed into a horseshoe shape. Keratinization of the cell follows, and the cytoplasm stains darker in consequence. All these stages may be found in the different cells of one plaque, and when keratinization occurs, it is possible to identify individual squamous carcinoma cells irrespective of plaque formation. Cell nests are rarely found in sputum films. The carcinoma cell does not phagocytose—a cardinal point in distinguishing it from the macrophage with which it is very easily confused in the early stage of neoplastic growth.

Space does not permit of a description of wet films and of frozen and paraffin sections, but the stained film method outlined above will amply repay careful study. It is possible thus to make a diagnosis of asthma, bronchial ulceration and chronic pulmonary edema, while it is of the greatest value in detecting bronchial carcinoma and will even enable one sometimes to gain corroborative evidence of pulmonary tuberculosis. The broad way to failure is to take the first portion of sputum which presents itself the straight and narrow way to success is to go over the specimen with a hand lens and select the particles for examination with discrimination. *Experientia docet*

## MAINE NEWS

### ANNUAL MEETING

The eighty-seventh annual meeting of the Maine Medical Association will be held at Poland Springs, Sunday, Monday and Tuesday, June 25, 26 and 27.

The central location of Poland Springs makes it the ideal situation for this meeting. The new management has granted reduced hotel rates with free parking of automobiles. Golf fees will be only one dollar for all-day playing. An orchestra will be available at dinner for entertainment and dancing. There will be an entertainment on Sunday evening.

## CORRESPONDENCE

### LICENSE SUSPENDED

*To the Editor* The license of Dr Roland O Parris, of Falmouth, was suspended for one month from April 20, 1939, because of negligence in the postoperative care of a patient.

STEPHEN RUSHMORE, M.D., *Secretary,*  
Board of Registration in Medicine.

State House,  
Boston.

### REFERENCE STANDARD FOR THIAMIN CHLORIDE (VITAMIN B<sub>1</sub>)

*To the Editor* Synthetic Crystalline Vitamin B<sub>1</sub> has now been made the U.S.P. reference standard for what has long been known as Vitamin B<sub>1</sub> but is now called Thiamin Chloride, and this reference standard is now available, having been supplied by the U.S.P. Board of Trustees, with the co-operation of the U.S.P. Vitamin Advisory Board. Orders for this new reference standard should be sent to the chairman of the Committee of Revision, 43rd Street and Woodland Avenue, Philadelphia.

Thiamin Chloride, as a crystalline substance, has been proposed for inclusion in the Second U.S.P. XI Supplement. If it is admitted, the physical and chemical tests will be sufficient to determine its quality and therapeutic activity but when present in preparations or in solution, or when a part of the vitamin B complex, its activity will have to be determined by the biological assay procedure recommended for official adoption.

E. FULLERTON COOK, *Chairman*  
U.S.P. Committee of Revision

43rd Street and Woodland Avenue,  
Philadelphia.

### SULFANILAMIDE AND DESQUAMATION OF THE SKIN

*To the Editor* For the past few months there has been considerable controversy between attending physicians and health authorities regarding children who have suffered from slight pharyngeal disturbances and who have later shown desquamation of the skin. Because of the possibility of their having had scarlet fever, these children have been sent home by school physicians, with loss of time from school and mental annoyance to the parents and attending physicians.

Recently I saw two cases of desquamation of the skin following the use of sulfanilamide. I think it would be well for medical inspectors of the health department to inquire whether or not such children had received sulfanilamide at the time of their illness, for the use of this drug might solve the mysterious desquamation of the skin, provided the attending physician were certain that there was no possibility of the diseases having been scarlet fever. At the present time, sulfanilamide is being given for almost every acute infection.

JOHN G. DOWNING, M.D.

520 Commonwealth Avenue,  
Boston

## REPORTS OF MEETINGS

### ALPHA OMEGA ALPHA LECTURE

At a regular lecture sponsored by the Harvard chapter of Alpha Omega Alpha, on Monday, January 16 at the

Harvard Medical School, President Donald Matson introduced the guest speaker, Dr Eugene F DuBois of the Russell Sage Institute of Pathology, Cornell Medical College, and the New York Hospital. Dr DuBois spoke on Heat Loss from the Human Body.

Dr DuBois described how he came to be interested in this study. His work in this field began twenty three years ago with Dr Joseph C. Aub, and they established some standards of basal metabolism based on body surface area. Receiving further stimuli from problems in air-conditioning and malaria therapy, the Russell Sage investigators six years ago decided to limit their field to the study of heat loss.

Dr DuBois presented lantern slide charts to show a normal twenty-four hour curve of heat production and loss. On waking in the morning, one's heat loss is almost equal to one's heat production, both being at a low level. The subject of the experiment took a short run, the heat production curve went up steeply but the heat loss curve lagged far behind, which meant that heat was being stored. The subject returned to rest and to take a cold shower, whereupon the loss of body heat became much greater than its production. When the subject went to bed at night, the curves gradually dropped to the equal low level at the start of the experiment.

The process was described as a balanced scale, with the pointer representing body temperature at 37°C. Heat loss, on a foundation of radiation, convection and vaporization, is favored by such factors as a cooler environment, increased skin circulation and an increase in sweating and panting, which will swing the balance toward lower temperatures. On the other side of the scale is heat production, based on fundamental oxidation of carbohydrate, fat and protein, and made variable by excitement, exercise, increased basal metabolic rate, and so on, and tending to move the pointer toward higher temperatures.

The factors involved in loss of body heat can be divided into physical and physiological ones. In considering the physical factors, it should be appreciated that man's specific heat being 0.82, which is lower than that of water, a temperature rise of 1°C in a 70-kg man requires the addition to the body of 57 calories. The skin has extraordinary heat insulating properties, compared with the conduction value of cork, which is 0.0007, epidermis, muscle and fat have values from 0.00047 to 0.00050. Man, in addition, has the power of changing the properties of his skin. A 70-kg man has 1.8 square meters of surface area and a temperature gradient from within outward of 1.8°C to 10 cm in depth. The skin is a 99-per-cent perfect black-body radiator, there being not much difference between the skins of Negroes and Whites. The amount of moisture exuded is also a factor.

The physiological factors deal with the vascular, nervous and endocrine systems. Blood flow from within outward transports heat to the surface. Over the veins one can detect colder streaks moving inward. The body is particularly able to control heat production and dissipation, and the amount of moisture in the skin. The skin is extremely sensitive to temperature changes, for example, the skin of the forehead has been found able to detect within two or three seconds a temperature change of 0.003 C.

Dr DuBois then took time to review briefly the literature on the subject to show how the study depended on the development of measuring instruments for determining values of heat loss by radiation, convection and vaporization. These are governed by physical laws. At the start of the work, he had difficulty in measuring convection, and Dr James G Hardy, a physicist, was asked to

The usual conferences will be held Monday and Tuesday mornings, but they will differ from those in the past in that several physicians will participate as leaders, each conference will run from 9 30 to 12 noon. There will be a clinicopathological session Monday afternoon. Monday evening a speaker from New York—name to be announced—will address the meeting. Three nationally known physicians will speak on Tuesday afternoon. Dr Morris Fishbein, editor of the *Journal of the American Medical Association* will be the speaker on Tuesday evening. Medical moving pictures will be provided, and special entertainment for the ladies.

#### WOMEN'S FIELD ARMY

The Women's Field Army reports that from January 23 to March 21 seventy-three districts were organized for complete participation in the 1939 educational campaign. This is most encouraging in view of the fact that almost all of this was done by mail. Every county is represented in the units organized.

In addition to the districts organized for active participation thirty will be covered by direct mail appeals and personal solicitations. Of this total, twelve districts have never participated in previous campaigns. With the permission of the Maine Medical Association and of Dr Edward H. Risley, chairman of the State Advisory Board, copies of the very fine editorial on the Women's Field Army, which appeared in the February issue of the *Journal of the Maine Medical Association*, were sent to all the daily newspapers and several of the weeklies, with the request that it be reprinted or that an article based upon it be given. This is bringing a most gratifying result and should answer conclusively the questions sometimes asked about the attitude of the physician and the Association toward the work of the Women's Field Army.

#### COUNTY MEETINGS

On April 11, Dr S J Thannhauser, of Boston, talked before the Knox County Medical Society, the title was Vitamin Deficiencies.

The Kennebec County Medical Society was addressed by Dr Samuel Levine, of Boston, on April 20, the title of his talk being Auscultation of the Heart.

On April 21, Dr Richard H. Overholt, of Boston, talked before the Cumberland County Medical Society, his topic was Some New Developments in the Management of Chest Lesions.

#### NOTES

The following physicians have recently become members of the Maine Medical Association: D Foster of Portland, Albert S Owen and E M Fuller, of Bath; H Grubin, of Lubec.

The following new panel discussions have been added to the list available for the county medical societies:

Cancer: Dr Edward H Risley, chairman, Waterville.  
Thoracic Surgery: Dr George E. Young, chairman, Skowhegan.

The Maine Public Health Association is conducting a Help Find Early Tuberculosis campaign urging people to become tuberculosis-conscious and tuberculosis-suspicious in order to cut down the large number of cases of advanced tuberculosis now being admitted to our sanatoriums.

A course in allergy is open, on application, to physicians of Maine under the auspices of the Bingham Associates. A

fee of \$25 is charged for the course, which is of one week's duration, but a fellowship fee of \$50 is allowed and a physician taking the course may obtain room and board at the hospital for \$10. Full information is available from Dr F T Hill, Waterville, or Dr Fred R. Carter, 22 Arsenal Street, Portland.

A teaching clinic was held at the Central Maine General Hospital on April 28, under the direction of Dr John Fraser, professor of obstetrics and gynecology, McGill University Faculty of Medicine, Montreal. A clinic was held in the morning, and ward rounds in the afternoon. In the evening Dr Fraser discussed "The Treatment of Hemorrhage in Late Pregnancy."

#### RÉSUMÉ OF COMMUNICABLE DISEASES IN MASSACHUSETTS FOR MARCH, 1939

DISEASES	MARCH 1939	MARCH 1938	FIVE YEAR AVERAGE*
Anterior poliomyelitis	0	0	0
Chickenpox	1181	1944	1341
Diphtheria	14	17	28
Dog bite	765	781	635
Dysentery bacillary	24	0	2
German measles	105	92	1238
Gonorrhea	384	463	432
Lobar pneumonia	900	654	652
Measles	4290	1259	4154
Meningococcus meningitis	5	9	19
Mumps	1015	1303	1165
Paratyphoid B fever	1	8	2
Scarlet fever	901	1712	1255
Syphilis	416	635	543
Tuberculosis pulmonary	345	291	315
Tuberculosis other forms	30	39	41
Typhoid fever	4	3	5
Undulant fever	3	4	2
Whooping cough	971	573	1146

\*Based on figures for preceding five years.

#### RARE DISEASES

*Diphtheria* was reported from Boston, 3, Cambridge, 1, Lawrence, 2, Medford, 1, Methuen, 2, Shrewsbury, 1, Taunton, 1, Woburn, 1, Worcester, 2, total, 14.

*Dysentery bacillary*, was reported from Boston, 1, Lowell, 1, Wrentham, 22, total, 24.

*Infectious encephalitis* was reported from Arlington, 1, Chicopee, 1, Norfolk, 2, total, 4.

*Meningococcus meningitis* was reported from Boston, 1, Gardner, 1, Southbridge, 1, Springfield, 2, total, 5.

*Paratyphoid B fever* was reported from Malden, 1, total, 1.

*Pfeiffer bacillus meningitis* was reported from Everett, 1, Lowell, 1, total, 2.

*Septic sore throat* was reported from Belmont, 2, Boston, 11, Fall River, 1, Lawrence, 1, Malden, 3, Taunton, 1, Wenham, 4, Westwood, 1, total, 24.

*Trachoma* was reported from Boston, 1, Milford, 1, Watertown, 1, Webster, 1, total, 4.

*Typhoid fever* was reported from Boston, 2, Framingham, 1, Saugus, 1, total, 4.

*Undulant fever* was reported from Gardner, 1, Kingston, 1, Lowell, 1, total, 3.

Lobar pneumonia, pulmonary tuberculosis, measles and undulant fever were reported above the five year average.

Scarlet fever, diphtheria, German measles, chickenpox and mumps were reported below the five year average.

Tuberculosis (other forms) showed record low figures for the third consecutive month.

Whooping cough, meningococcus meningitis and typhoid fever were reported below the five year average.

Animal rabies showed record low incidence for the fourth consecutive month. Foci in Canton and Haverhill were active.

### SULFANILAMIDE AND DESQUAMATION OF THE SKIN

*To the Editor* For the past few months there has been considerable controversy between attending physicians and health authorities regarding children who have suffered from slight pharyngeal disturbances and who have later shown desquamation of the skin. Because of the possibility of their having had scarlet fever, these children have been sent home by school physicians, with loss of time from school and mental annoyance to the parents and attending physicians.

Recently I saw two cases of desquamation of the skin following the use of sulfanilamide. I think it would be well for medical inspectors of the health department to inquire whether or not such children had received sulfanilamide at the time of their illness, for the use of this drug might solve the mysterious desquamation of the skin provided the attending physician were certain that there was no possibility of the diseases having been scarlet fever. At the present time, sulfanilamide is being given for almost every acute infection.

## REPORTS OF MEETINGS

### ALPHA OMEGA ALPHA LECTURE

At a regular lecture sponsored by the Harvard chapter of Alpha Omega Alpha, on Monday, January 16, at the

Harvard Medical School, President Donald Matson introduced the guest speaker, Dr Eugene F DuBois of the Russell Sage Institute of Pathology, Cornell Medical College, and the New York Hospital. Dr DuBois spoke on "Heat Loss from the Human Body."

Dr DuBois described how he came to be interested in this study. His work in this field began twenty three years ago with Dr Joseph C Aub, and they established some standards of basal metabolism based on body surface area. Receiving further stimuli from problems in air-conditioning and malaria therapy, the Russell Sage investigators six years ago decided to limit their field to the study of heat loss.

Dr DuBois presented lantern slide charts to show a normal twenty-four hour curve of heat production and loss. On waking in the morning, one's heat loss is almost equal to one's heat production, both being at a low level. The subject of the experiment took a short run, the heat production curve went up steeply but the heat loss curve lagged far behind, which meant that heat was being stored. The subject returned to rest and to take a cold shower, whereupon the loss of body heat became much greater than its production. When the subject went to bed at night, the curves gradually dropped to the equal low level at the start of the experiment.

The process was described as a balanced scale, with the pointer representing body temperature at 37°C. Heat loss, on a foundation of radiation, convection and vaporization, is favored by such factors as a cooler environment, increased skin circulation and an increase in sweating and panting, which will swing the balance toward lower temperatures. On the other side of the scale is heat production, based on fundamental oxidation of carbohydrate, fat and protein, and made variable by excitement, exercise, increased basal metabolic rate, and so on, and tending to move the pointer toward higher temperatures.

The factors involved in loss of body heat can be divided into physical and physiological ones. In considering the physical factors, it should be appreciated that man's specific heat being 0.82, which is lower than that of water, a temperature rise of 1°C in a 70-kg man requires the addition to the body of 57 calories. The skin has extraordinary heat insulating properties, compared with the conduction value of cork, which is 0.0007, epidermis, muscle and fat have values from 0.00047 to 0.00050. Man, in addition, has the power of changing the properties of his skin. A 70-kg man has 1.8 square meters of surface area and a temperature gradient from within outward of 1.8°C to 10 cm in depth. The skin is a 99 per cent perfect black body radiator, there being not much difference between the skins of Negroes and Whites. The amount of moisture exuded is also a factor.

The physiological factors deal with the vascular, nervous and endocrine systems. Blood flow from within outward transports heat to the surface. Over the veins one can detect colder streaks moving inward. The body is particularly able to control heat production and dissipation, and the amount of moisture in the skin. The skin is extremely sensitive to temperature changes. For example, the skin of the forehead has been found able to detect within two or three seconds a temperature change of 0.003°C.

Dr DuBois then took time to review briefly the literature on the subject to show how the study depended on the development of measuring instruments for determining values of heat loss by radiation, convection and vaporization. These are governed by physical laws. At the start of the work, he had difficulty in measuring convection, and Dr James G Hardy, a physicist was asked to

contribute his efforts. Dr. Hardy invented the radiometer, which Dr. DuBois proceeded to describe. It measures radiation heat, which comes in the 5 to 20  $\mu$  wavelength zone, and also skin temperatures, since the skin is almost a perfect black body radiator.

In 1934 Dr. DuBois began experiments with the purpose of reducing variables to a minimum value. This required the accumulation of data on many people as subjects. He described the procedure in obtaining these readings before giving the results obtained. The remainder of his presentation consisted of the results of such experiments.

It was found that at an environmental temperature of 22°C the feet were much colder than the head and the toes even colder than the air. The toes are good heat dissipators by their surface area and sweating, and they are a long distance from the central heating. However, as the room temperature warmed toward 35°C, these areas more nearly approached each other in warmth, the greatest rise in temperature being in the feet and toes.

The breaking down of data obtained in a series of such experiments into components of radiation, convection and vaporization, revealed that with a change in temperature from 20 to 35°C the amount of heat loss by radiation declined to zero, as did the amount by convection, but not so regularly, and that heat loss by vaporization increased. The region of balance was at 28 to 30°C, this can be called the "comfort zone," in which heat loss equals heat production and the body is easily able to control loss by means of its vasomotor apparatus. At the 22°C end of the scale, heat loss is much greater than heat production, and what the body can do in the way of reducing vaporization to a minimum still is not enough, since radiation and convection are beyond control at this point. At the warmer end of the scale, heat loss is a little greater than heat production, on account of a temporary overcompensation by vaporization.

A comparison of men and women reveals the interesting fact that in men heat production is relatively constant, though heat loss may change, whereas in women at air temperatures of 28 to 36°C the rate of heat production seems to parallel closely the rate of heat loss.

Further experiments studied work, malarial chills and the use of a fan. During a chill, the rate of heat production goes up. A fan turned on the subject in a room as warm as himself will make him feel more comfortable, although actually the components of heat loss do not change their values at all.

Dr. DuBois concluded by describing what goes on in a game of squash racquets. During the game, heat production rises tremendously and the rectal temperature of the contestant goes from 37 to 39°C, however, the temperature of the skin falls. The value for radiation goes down, that for convection rises moderately, heat loss by vaporization is tremendously increased and remains high during the after game rest period. Thirty six minutes after the game ends, the rectal temperature is back to normal and the skin temperature rises from its low level. This proves that excess heat is lost from a cool skin rather than from a warm one.

Dr. DuBois illustrated dramatically the curves made by heat production and heat dissipation during and after this game of squash. Heat production during violent exercise rises in the direction of carbohydrate metabolism faster than heat loss rises in the direction of vaporization, and during the rest period following falls back to normal faster than does heat loss.

## NOTICES

### TUMOR CLINIC, BOSTON DISPENSARY

Each Tuesday and Friday morning, 10 00 to 12 30, there is a meeting of the Tumor Clinic of the Boston Dispensary, a unit of the New England Medical Center. Neoplasms of various sorts are seen and discussed, and when there is an indication, are treated with radium or high-voltage x-ray. Physicians are invited to visit this clinic. They may bring patients for aid in diagnosis or may refer patients to the clinic following which a report will be returned to the referring physician. A limited number of beds are available for diagnostic study and for treatment.

### JOSEPH H. PRATT DIAGNOSTIC HOSPITAL

Dr. A. A. Berg, of the Mount Sinai Hospital, New York City, will discuss "The Surgical Aspects in the Management of Ulcerative Colitis" on Tuesday morning, May 9, from 9 00 to 10 00. Dr. K. S. Andrews and Dr. Henry Lerner will discuss the secondary manifestations.

### BOSTON CITY HOSPITAL

The monthly clinicopathological conference will be held at the Boston City Hospital on Wednesday, May 10, at 12 o'clock noon, in the Pathological Amphitheater.

JOSEPH E. HALLISEY, M.D., *Secretary,*  
Medical Staff

### NORFOLK DISTRICT MEDICAL SOCIETY

The eighty ninth annual meeting of the Norfolk District Medical Society will be held at the Hotel Somerset, Boston, on Wednesday, May 10.

The business meeting will begin at 6 00 p.m., dinner will be served at 6 45. Following the dinner, there will be a talk by Mr. James H. Powers, editor of foreign affairs for the *Boston Globe*, whose subject will be "American Foreign Policy Comes of Age."

DAVID D. SCANNELL, M.D., *President*  
FRANK S. CRUICKSHANK, M.D., *Secretary*

### MASSACHUSETTS ITALIAN MEDICAL SOCIETY

The regular meeting of the Massachusetts Italian Medical Society will be held at the Hotel Kenmore, Boston, on Friday evening, May 26, at 9 00. Dr. Elliott C. Cutler will speak on Biliary Surgery. Including diagnosis and treatment.

A general discussion will follow. The medical profession is cordially invited to attend.

CARL F. MARALDI, M.D., *Secretary*

### NEW ENGLAND OBSTETRICAL AND GYNECOLOGICAL SOCIETY

The eleventh annual spring meeting of the New England Obstetrical and Gynecological Society will be held in Portland, Maine, on Wednesday, May 24.

### NATIONAL HOSPITAL DAY

National Hospital Day will again be observed in all the New England hospitals on Friday, May 12. Open house will be observed in some hospitals, while special programs

and exhibits will be put on by others. The committee for New England consists of the National Hospital Day armen from each of the New England states. Radio programs have been arranged through Stations EEL, WAAB, and WCOP, as follows:

May 10 9 30 a. m. Station WAAB. A round table discussion by Dr. Warren Cook, superintendent of the New England Deaconess Hospital, and Dr. Joseph P. Leone, superintendent of the Quincy City Hospital and chairman of National Hospital Day for Massachusetts and New England, under the auspices of the Massachusetts Department of Public Health.

Topic "The Community Hospital and National Hospital Day"

May 11 7 00-7 30 p. m. Station WCOP. A round table discussion by the state chairmen from all the New England states.

Topic "The Modern Hospital"

May 12 4 00 p. m. Station WEEI. National Hospital Day

Speakers: Mr. Edward Dana, director of Associated Hospital Service Corporation of Massachusetts, and Dr. Charles Wilinsky, director of the Beth Israel Hospital.

## SOCIETY MEETINGS AND CONFERENCES

### CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY, MAY 8

#### TUESDAY MAY 9

- \*9 10 a. m. Ulcerative Colitis. Dr. A. A. Berg, Dr. K. S. Andrews and Dr. Henry Lerner. Joseph H. Pratt Diagnostic Hospital.
- 10 a. m. 12 30 p. m. Tumor clinic. Boston Dispensary.

#### WEDNESDAY MAY 10

- 9 10 a. m. Hospital case presentation. Dr. S. J. Thannhauser. Joseph H. Pratt Diagnostic Hospital.
- 12 m. Clinicopathological conference. Children's Hospital amphitheater.
- 1 p. m. Monthly clinicopathological conference. Boston City Hospital Pathological amphitheater.
- 6 p. m. Norfolk District Medical Society. Hotel Somerset, Boston.

#### THURSDAY MAY 11

- \*9 10 a. m. Macrocytic Anemia and Liver Therapy. Dr. W. P. Murphy. Joseph H. Pratt Diagnostic Hospital.

#### FRIDAY MAY 12

- National Hospital Day.
- 9 10 a. m. Medical Aids to Crime Detection. Dr. E. V. Hill. Joseph H. Pratt Diagnostic Hospital.
- 10 a. m. 12 30 p. m. Tumor clinic. Boston Dispensary.
- 1 p. m. Clinical meeting of the Children's Medical Service. Massachusetts General Hospital. Ether Dome.

#### SATURDAY MAY 13

- 9 10 a. m. Hospital case presentation. Dr. S. J. Thannhauser. Joseph H. Pratt Diagnostic Hospital.
- 10 a. m. 12 m. Staff rounds of the Peter Bent Brigham Hospital. Conducted by Dr. Henry A. Christian.

Open to the medical profession.

- May 7—Health Lecture. Quincy City Hospital. Page 636. Issue of February 23.
- May 7-15—International Congress of Military Medicine and Pharmacy. Page 501. Issue of September 29.
- May 9—Joseph H. Pratt Diagnostic Hospital. Page 763.
- May 10—Monthly clinicopathological conference, Boston City Hospital. Page 763.
- May 11—Pentucket Association of Physicians. 8 30 p. m. Hotel Bardett, 125 Main Street, Haverhill.
- May 12—National Hospital Day. Page 763.
- May 12 and 13—American Heart Association. Page 547. Issue of March 23.

May 13-16—American Board of Obstetrics and Gynecology. Page 457. Issue of March 9.

May 14-20—American Physicians Art Association. Page 404. Issue of March 2.

May 15-19—American Medical Association. St. Louis, Missouri.

May 22, 23, and 24—American Association for the Study of Gout. Page 405. Issue of March 2.

May 24—New England Obstetrical and Gynecological Society. Page 766.

May 26—Massachusetts Italian Medical Society. Page 768.

JUNE 5, 6, 7, and 8—American Association of Industrial Physicians and Surgeons. Page 581. Issue of March 30.

JUNE 6, 7, and 8—Massachusetts Medical Society. Worcester.

JUNE 12-17—Symposium on the Public Health Significance of the Virus and Rickettsial Diseases. Page 125. Issue of January 19.

JUNE 26-29—National Tuberculosis Association. Page 936. Issue of December 8.

SEPTEMBER—Boston Psychoanalytic Institute. Page 450. Issue of September 22.

SEPTEMBER 11-15—American Congress on Obstetrics and Gynecology. Page 938. Issue of December 8.

SEPTEMBER 15-28—Pan Pacific Surgical Association. Page 863. Issue of November 24.

OCTOBER 23-NOVEMBER 3—New York Academy of Medicine. Page 581. Issue of March 30.

FALL 1939—Temperature Symposium. Page 218. Issue of February 2.

## DISTRICT MEDICAL SOCIETIES

### ESSEX SOUTH

May 10—Page 649. Issue of April 13.

### NORFOLK

May 10—Page 768.

### WORCESTER

May 10—Worcester Country Club—annual meeting.

## BOOKS RECEIVED FOR REVIEW

*You Can't Eat That!* A manual and recipe book for those who suffer either acutely or mildly (and perhaps unconsciously) from food allergy. Helen Morgan. 330 pp. New York: Harcourt, Brace & Co., 1939. \$2.50.

*The Principles and Practice of Ophthalmic Surgery*. Edmund B. Spaeth. 835 pp. Philadelphia: Lea & Febiger, 1939. \$10.00.

*The Circulation of the Brain and Spinal Cord. A symposium on blood supply*. The proceedings of the Association for Research in Nervous and Mental Disease, New York, December 27 and 28, 1937. 790 pp. Baltimore: Williams & Wilkins Co., 1938. \$10.00.

*Failure of the Circulation*. Tinsley R. Harrison. 502 pp. Baltimore: The Williams & Wilkins Co., 1939. \$4.50.

*The Clinical Diagnosis of Swellings*. C. E. Corrigan. 313 pp. Baltimore: The Williams & Wilkins Co., 1939. \$4.00.

*Thus We Are Men*. Walter Langdon Brown. 344 pp. New York: Longmans, Green & Co., 1939. \$3.50.

*Holmes of the Breakfast-Table*. M. A. D. Howe. 171 pp. London and New York: Oxford University Press, 1939. \$2.50.

*Traite de Biocolloïdologie*. Tome V. *État Colloïdal et Médecine*. Fascicule 1. *Le Sang*. W. Kopaczewski. 151 pp. Paris: Gauthier-Villars, 1937. 60 Fr. fr.

*Traite de Biocolloïdologie*. Tome V. *État Colloïdal et Médecine*. Fascicule 2. *Liquides et Tissus Organiques*. W. Kopaczewski. 299 pp. Paris: Gauthier-Villars, 1938. 100 Fr. fr.

*Sleep Your Life's One Third*. Maurice Chudeckel. 183 pp. New York: The Saravan House, 1939. \$2.00.

*Preclinical Medicine. Preclinical states and prevention of disease*. Malford W. Thewlis. 223 pp. Baltimore: The Williams & Wilkins Co., 1939. \$3.00.

*Hypertension and Nephritis*. Arthur M. Fishberg. Fourth edition, thoroughly revised. 779 pp. Philadelphia: Lea & Febiger, 1939. \$7.50.

*Manual of Toxicology* Forrest R. Davison 241 pp  
New York Paul B. Hoeber, Inc., 1939 \$2.50

*Community Health Organization A manual of administration and procedure primarily for urban cases* Edited by Ira V. Hiscock Third edition 318 pp New York The Commonwealth Fund, 1939 \$2.50

*Les Calculs de l'Uretere* Pierre Macquet. 186 pp  
Paris Masson et Cie, 1939 45 Fr. fr

*Les Erreurs et les Fautes en Urologie* L. Strominger  
176 pp Paris Masson et Cie, 1939 45 Fr. fr

*Actualites Medico-Chirurgicales* Par les chefs de clinique de la Faculte de Medecine de Marseille Quatrieme serie. 192 pp Paris Masson et Cie, 1939 30 Fr. fr

*Studies on Pain Conduction in the Trigeminal Nerve A contribution to the surgical treatment of facial pain* Olof Sjoqvist 139 pp New York G. E. Stechert & Co., 1938 \$3.00

*Angina Pectoris Nerve pathways physiology, symptomatology and treatment* Heyman R. Miller 275 pp Baltimore The Williams & Wilkins Co., 1939 \$3.25

## BOOK REVIEWS

*Drug Addicts Are Human Beings The story of our billion dollar drug racket—how we created it and how we can wipe it out* Henry S. Williams 273 pp Washington Shaw Publishing Co., 1938 \$2.50

Probably most people who read this book will be surprised to learn the estimated number of morphine addicts in the United States and the number of reputable physicians who have been imprisoned or have paid fines because of convictions in courts for the alleged illegal treatment of these addicts.

One rarely finds a more zealous enterprise to bring about a reform than that shown in this volume where the author tries to convince doctors that the victims of the morphine habit are sick persons worthy of medical treatment. He also tries to teach lawyers and judges that the Harrison Narcotic Act has been misunderstood and misapplied by agents of the Narcotic Bureau in dealing with the problems involved in the medical care of addicts.

Quotations of decisions of the Supreme Court of the United States are presented and show that the Harrison Narcotic Act as drawn and amended is a revenue measure only, and that nothing in the law justifies the prosecution of reputable physicians who have treated morphine addicts. The assumption of certain judges and lawyers that the regulations of the Narcotic Bureau with respect to prescribing appropriate doses of morphine to addicts outside of jails and government hospitals has the force of law is also found to be unsound. This interpretation of the regulations has led to the closing of well-organized clinics served by well-qualified doctors, and the imposition of fines and jail sentences on many reputable physicians. Because of these court actions, doctors have declined to treat these addicts, with the result that these unfortunate people have been led to deal with the dope peddlers and thus there has been established the so-called billion-dollar racket.

The purveyors of the drug charge a dollar or more for a grain of morphine, whereas when the drug is dispensed under medical care the price is only a few cents. This deplorable situation prevents the effective treatment of ambulatory addicts and perpetuates the racket under properly regulated medical treatment the peddler would go out of business.

The Narcotic Bureau seems to have found it easier to convict a doctor even if he prescribed properly regulated

doses for an addict than to eliminate the peddler. According to Dr. Williams it seems to be more gratifying for the bureau to prosecute a doctor than to deal with the real criminal. The situation seems to have changed for the better since the action of two federal judges as detailed in this book, who, after careful study of the situation, have rendered decisions to the effect that there is no legal justification for the prosecution of doctors who have treated morphine addicts with the purpose of meeting the medical problems involved. With these two decisions the author contends that a logical method of dealing with the situation will be brought about which will return the addict to medical care and the peddler will be deprived of his income and return from the field. This may be utopian, but the arguments advanced are interesting.

The author does not hesitate to use sarcasm of a high order in his vigorous denunciation of mistaken policies of the Narcotic Bureau and the methods employed by its officials. The book is well written, contains much information and the arguments seem to be sound.

With the facts before the public the question arises as to the position of organized medicine in efforts to have abuses eliminated and logical procedures adopted.

*Classic Descriptions of Disease With biographical sketches of the authors* Ralph H. Major Second edition. 727 pp Springfield, Illinois, and Baltimore Charles C. Thomas, 1939 \$5.50

This well known book was first issued in 1932 and had a wide circulation. It was deservedly popular for nothing of its type was available in English. At the time it was issued, the book was criticized on the basis of its incompleteness and the numerous mistakes in dates and sometimes actually in text. With the new edition, the author has not only revised his texts but he has carefully checked dates and references. In many places, moreover, the translations have been improved, although occasionally they leave something to be desired. The principal change in the second edition, however, is the added material. For this, every student of the history of medicine will be grateful. There are new sections on malaria and yellow fever. The biographical sketches have, in part, been rewritten and the index completely revised. This edition can be more highly recommended than the first.

*Hygiene Manual of public health* J. R. Currie. 324 pp Baltimore William Wood & Co., 1938 \$5.00

Although this book is designed for the instruction of medical students, practitioners interested in personal and public hygiene will find useful information in every chapter.

Beginning with a brief account of the early efforts to interest people in the underlying principles relating to personal and community health, the subsequent chapters explain hereditary and environmental factors which affect the well being of the human race. The details of the public health administration of Great Britain are set forth. Chapters devoted to the etiology and treatment of infectious and communicable diseases are well written and will be useful for reference. That part devoted to the poison gases used in warfare, with precautions to be observed, are timely under existing conditions on the other side of the ocean.

The author is an authority on public health administration and has written a book which is worthy of a place in the doctor's library.

## THE JOSEPH H PRATT DIAGNOSTIC HOSPITAL

SAMUEL PROGER, M.D.\*

BOSTON

IF THE Joseph H Pratt Diagnostic Hospital in Boston simply added a few beds to those already available in New England for medical care, it would hardly justify itself. It has been constructed with the idea that as the focal point in a broad program for the better distribution of medical care it can serve a unique and useful purpose in New England medicine. A description of the planned functions of the hospital then resolves itself into a description of this broad program for the advancement of medicine, particularly in non-metropolitan areas, to which end the Bingham Associates Fund has devoted itself for some seven years.

The Joseph H Pratt Diagnostic Hospital, like the program to which it is dedicated, represents the humanitarianism of William Bingham, 2nd, a real philanthropist. The Bingham Associates Fund, through which the hospital and program have been made possible, was under the supervision of Dr. John G. Gehring, its first president, from 1931 to 1933. During the last six years (since Dr. Gehring's death) the Fund has been under the active, far-sighted direction of Dr. George B. Farnsworth, its second president.

The general aim is essentially that described by Dr. Joseph H. Pratt<sup>1</sup> in 1932, to which reference is made in *The Final Report of the Committee on the Costs of Medical Care*,<sup>2</sup> as follows: "An arrangement embodying some of the relations between branches and medical centers here proposed has been effected between the New England Medical Center in Boston and the Rumford (Maine) Community Hospital. It is described by Dr. Joseph H. Pratt. It is largely in recognition of this pioneer work that the hospital bears its name."

### PLANNED PROGRAM AND GENERAL PROBLEM

The plan of the Bingham Associates Fund is designed to extend into small communities the medical advantages of a metropolitan center by

Assistant professor of medicine, Tufts College Medical School; medical director, Joseph H. Pratt Diagnostic Hospital.

direct and indirect contacts between these elements, arranged on a permanent working basis. It is intended that small communities shall maintain their opportunities for independent work, but that it shall be integrated with that of larger centers.

Unquestionably many of the benefits of medical advances ultimately reach small communities under almost any circumstances. At present, however, this dissemination is haphazard, irregular and slow. It is our hope to establish regular and directed channels for the transmission of medical developments. Accordingly, through hospital centers of various gradations, a model has been set up which involves the Tufts College Medical School and New England Medical Center in Boston as its central medical-school-hospital base, the Central Maine General Hospital in Lewiston, Maine, as its regional center, and community hospitals in Bath, Brunswick, Rockland, Augusta, Rumford and Skowhegan as its smaller affiliated units. The latter hospitals are within eighty miles of Lewiston and are easily accessible by train or automobile.

A regional center similar to the one in Lewiston is being established in Bangor at the Eastern Maine General Hospital for the purpose of offering direct aid to a group of small hospitals in the northeastern part of Maine. This, like the already established group, is intended as a model to serve as a basis for further development.

The plan of establishing graded centers (university-hospital medical center, regional centers and community hospitals) has proved effective. Such an arrangement tends to enable the units, which are graduated according to size and location, to be mutually stimulating. When, on the other hand, a direct association is attempted between hospitals too distant from one another and varying too greatly in size, equipment and facilities, the relation becomes one of dependence on the part of the smaller unit, and impersonal and disinterested help on the part of the larger one.

[illegible]

The author is an expert in the field of the study of the history of the Jewish people in the Diaspora.

## DIAGNOSTIC AID

In order to carry on our program, we require a teaching and a clinical base. The Tufts College Medical School is the teaching base, the New England Medical Center and, primarily, the Joseph H Pratt Diagnostic Hospital form the clinical base. The clinical base should be not a hospital which will take over the hospital work of the affiliated communities,—this would be difficult and psychologically undesirable,—but a clearing-house for such problems as the latter, because of their limited facilities are unable to handle to the best advantage of the patients. The base hospital, then, serves as a complement to and not a substitute for the affiliated hospitals.

Unquestionably, one of the most important aids is a well-trained diagnostician. This, an institution especially devoted to diagnostic work is best able to supply. The Joseph H Pratt Diagnostic Hospital, with a large and especially trained personnel, is prepared to offer diagnostic help in the more obscure problems. Such help is available directly to the physician in the small community or through his local hospital. Patients are accepted directly from a physician in rural communities only when he believes that the local or nearby hospital facilities for study are inadequate. This decision must rest with the referring physician.

Through our schedule of undergraduate and postgraduate instruction, it is hoped that ultimately most if not all the physicians who make use of the Diagnostic Hospital will become thoroughly familiar with its work. The utilization of the hospital can serve as an effective means of continued contact with and instruction from the central institution through study of the physician's own cases. Such instruction is personal and very real, and can aid in maintaining contacts from undergraduate days through repeated postgraduate courses. In addition, the diagnostic work can serve as the dynamic force which will weld and vitalize the administrative, clinical and pedagogic aspects of the entire program. Through actual work with patients these aspects assume a more direct and tangible meaning.

It is our aim to stimulate a desire for better diagnostic work, more intelligent and efficient treatment will naturally follow. There are probably two factors which more than any others dampen the desire for professional diagnostic help: fear of the referring physician that he may be found wrong, and hence fall in the estimation of his patient, and the idea that he will lose the patient by referring him to another physician or to an institution. That such considerations should not exist is beside the point, the fact is, they do exist and

they should be recognized and arrangements made accordingly.

The policies of the hospital are designed to overcome these difficulties. For this reason, no patient is admitted unless sent by a referring physician, to whose care the patient is finally discharged. The referring physician at all times maintains complete control over the disposal of the patient. Correspondence is confined to him, and subsequent admissions can be arranged only through him. A complete report of findings, with diagnosis and recommendations, is sent to him, and as little information as possible is divulged to the patient. If the latter raises questions, as frequently happens, he is informed that his own physician will receive all the information and recommendations which we have to offer, and is told that all questions must be referred to this physician. If the hospital diagnosis and recommendations differ from those already given the patient by the referring physician, the latter is free to explain this difference as he sees fit. Essentially, the desire is to eliminate any possible factor which may influence a physician to wait until it is too late for a consultation, where he might otherwise have sought aid earlier.

Of course, no policy is justifiable which protects the physician to the detriment of the patient, and this may appear to be the case here. However, there can be no gainsaying that the relation between the doctor and the patient is a much more important one than that between an institution and the patient. On the physician falls the responsibility for putting to good use the information which the hospital can supply. The application of such information, which may involve close supervision and prolonged care, must be made as free from difficulties as possible if the patient is to receive the maximum benefit. It is the purpose of the hospital to help the patient through his physician, and to improve the practice of medicine in small communities by offering help to its physicians.

It must be emphasized that no indictment is intended of the capabilities of general practitioners. The implication is only that no physician today can be wholly self-sufficient, for the simple reason that it is humanly impossible for one person to encompass all medical knowledge.

Another factor which tends to decrease the demand for diagnostic aid is the development of a smugness and a complacency that often go with isolation and the lack of information. Our efforts at postgraduate education are designed to overcome this situation, and in a small way are successful, as is attested by the increasing number of patients referred for special studies. Education

The great advances in medicine, except for those in the field of public health, have given advantages chiefly to those practicing in metropolitan centers, where improvements have been more and more concentrated, so that finally there have developed such magnificent centers of advanced thought and practice in medicine as the Medical Center in New York City, the New York Hospital, the Lakeside Hospital and the Johns Hopkins Hospital. The influence of these institutions has gradually become greater, but relatively more concentrated, as rapid growth has occurred. The diffusion of this influence into small communities has been perhaps slower than necessary, largely because there has been no directed plan. Figuratively, as well as literally, such institutions have tended to grow into the skies. It is our purpose to direct development outward instead of upward, horizontally instead of vertically. A more or less direct means for the spread of the new developments of the metropolitan medical centers to rural communities would admittedly be desirable, and a planned program for this purpose is the essential aim of the Bingham Associates Fund.

Most plans for the improvement of rural medicine entail postgraduate instruction, subsidies to physicians in small communities, and the establishment of community hospitals or other facilities for group practice. Such plans are obviously directed toward overcoming the two major defects of rural medicine, namely inadequate local facilities and advantages, and insufficient numbers of physicians. Unfortunately, it is the general opinion that they have not been entirely successful. The principal reasons are self-evident.

Some of the problems involved in postgraduate instruction are described below. As for subsidies, it would appear that where financial backing is certain and regular, the initial problem of securing well-trained men for small communities can be thus attacked. However, if, as is apparently the case, the conditions under which practice must be carried on in small communities are so unattractive as to fail to interest young graduates, a more logical approach to the problem would seem to lie in the direction of efforts toward making such practice more attractive. Automobiles, good roads, radios and other material advantages have overcome many of the social and broader cultural handicaps once associated with life in small communities. It remains to carry corresponding medical advances into these areas, and when this has been accomplished, young physicians may be expected to settle gladly in them. It will no longer be necessary to lure them by the offer of subsidies, they will instead be attracted by the opportunity to practice medicine under conditions comparing

favorably with those in the medical centers in which they were trained.

The establishment of hospitals in rural communities is of unquestionable value, for among other things such units may offer the physical requirements for the utilization of the more modern methods of medicine. However, an expensive surgical unit does not ensure good surgery, a complete x-ray apparatus does not predicate accurate x-ray diagnosis, and a well-equipped laboratory does not guarantee scientific aid in medical management. In fact, such facilities may do more harm than good if not intelligently employed. It is only human to be lulled into false security by trusting blindly to the wisdom represented by awesome and expensive apparatus. It is natural to want to shift responsibility, and what better object can be found to which to shift it than some inanimate, unresponsive, shiny machine which is reputed to give us such and such reliable information? It is also human to have great confidence in impressive things about which we know little or nothing. A surgeon may actually be misled into a false belief in his sufficiency by the impressive display of all the modern equipment which he employs. A physician may wrongly give assurance concerning a patient's heart because "the electrocardiogram was normal," and a patient may be permitted to suffer untold mental anguish because x-rays were inaccurately interpreted as showing cancer. No medical weapons are deadlier than those of the pseudoscientist.

It is plain, then, that upon those who make modern facilities available to rural communities a great responsibility exists in assuring the proper, continued use of these facilities. It is in this latter respect that present programs for the advancement of rural medicine have not been entirely successful. If properly utilized, a community hospital can be the most effective unit in a program for the advancement of rural medicine, for it is ultimately the community hospital which will determine whether good or poor medicine is to be practiced in the community. It is therefore toward the improvement of small community hospitals that one of the principal features of our program is directed, namely the extension of services between such hospitals, larger intermediary units and a metropolitan center.

The program has three branches, each representing an approach to the general problem from another angle, the whole program being a coordinated effort toward making better medical care available to more people of New England, particularly in non-metropolitan areas. The three are as follows: diagnostic aid, hospital extension services and postgraduate education, as described below.

at least within a year after they have been instituted at the medical-school-hospital center. To the degree that supervision and instruction are essential for best results, our program for laboratory aid to small community hospitals appears to be adequate. It is significant that the supervision and instruction are given in Lewiston and Boston, and not in the community hospital. If the latter were the case, there would be a justifiable tendency to resent intrusion. During the two months when the technician is away from the community hospital, a well-trained itinerant technician serves as substitute.

The pathological service is organized in the following way. Each community hospital is expected to send all its specimens routinely to the pathologist at the Central Maine General Hospital, who sends back a report to the hospital. He also has the opportunity, in all questionable cases, of consulting with Dr. H. E. MacMahon, professor of pathology at Tufts College Medical School. In this way the latter is available to all the small hospitals on those cases in which his special knowledge is needed, whereas the routine work is adequately handled through Lewiston. The pathologist at Lewiston is also available for postmortem examinations and clinicopathological conferences at the small hospitals.

Under the arrangement for x-ray service, the radiologist at the Central Maine General Hospital visits the community hospitals one morning or afternoon each week, at which time he reviews with the local radiologist all the films of the preceding week and performs what fluoroscopies have been held over for him. He is also available at all times in Lewiston for interpretation of emergency films. We have arranged, through a fellowship, for the Lewiston radiologist to attend the weekly diagnostic x-ray conferences each Wednesday afternoon at the Massachusetts General Hospital, where he has an opportunity to present a limited number of films for group consultation. Ultimately, therefore, the community hospitals, through the Lewiston radiologist, have this Massachusetts General Hospital consultation service at their disposal. Thus, as in the pathological program, the Boston unit is utilized only where it can be most helpful, namely in unusual cases.

As to the electrocardiographic program, a course of one week's duration in the interpretation of electrocardiograms was given at the New England Medical Center to representatives of the community hospitals selected by their own groups. The course was furnished without charge on the condition that the hospital purchase an electrocardiograph. From the community hospitals the local electrocardiographer sends a copy of every

tracing to the Lewiston electrocardiographer, whose reports then become available for check by the physician in the community hospital. The tracings that are difficult to interpret are then sent from Lewiston to Boston, where several cardiologists are available for consultation when necessary. In this manner, again, the small hospitals have available the best authorities on interpretation of electrocardiograms, when and as they are needed. At the same time, the electrocardiographer of the local hospital is given constant opportunity for supervised training and improvement. It has been our impression that small community hospitals should not have an electrocardiograph unless some satisfactory arrangement is made for the intelligent interpretation of the tracings.

The method for offering aid in dietetics is similar to that described for laboratory work. Arrangements are made for the dietitian from each community hospital to spend one month each year in Boston, where she is given instruction, so that she may be kept informed of the rapid developments in this important field.

The library service is now getting under way. Every four days, each community hospital receives from the library of the regional center in Lewiston five medical journals, which are prominently displayed and remain in each hospital for four days, after which they are sent on to a neighboring hospital. During twenty-eight days of each month, each community hospital receives thirty-five medical journals. Reprints of almost all the articles can be obtained through the library at the Central Maine General Hospital, which is also equipped to supply the bibliographical material to any of the staff members of the affiliated hospitals who may wish to make a more complete review of the literature in regard to a special case or for aid in preparing a paper. The library in Lewiston, in turn, is affiliated with the Boston Medical Library, and can obtain literature on unusual subjects from the latter.

The services which we hope soon to be able to install are in nursing, administration and anesthesiology.

The details of organization of the various services are put into operation after being presented to and discussed by a committee of representatives of the hospitals involved, each being represented by a staff physician, the superintendent and a member of the lay board. This assures interested cooperation and a practical appraisal of local problems.

As indicated above, the community hospitals surrounding Lewiston are easily accessible. But this is not essential. If the community hospitals were scattered as far distant as two hundred miles from

is, among other things, a process of making clear the ever-increasing extent of our ignorance

It is said that the general practitioner can satisfactorily care for 80 or 90 per cent of his patients without the aid of a specialist. On the other hand, from 80 to 90 per cent of all illness, exclusive of the more severe neuroses, is either self-limited, relatively easily managed or unresponsive to treatment. If the practitioner can care satisfactorily for this percentage of his patients, does he? Or does any physician, for that matter? There must be a clear distinction between what *can* be done and what *is* done. A youngster with a simple sinus arrhythmia or perhaps a soft pulmonic systolic murmur does not require a specialist, in fact, he requires no physician at all. But he may be subjected to the shock of being told he has heart disease, or even of being put to bed for several months because of lack of knowledge of what he does not have, namely heart disease. There are many similar examples. We all encounter such cases frequently, and at times we are guilty of such errors. These cases are included among the patients who can be cared for by the practitioner, but they are evidently cases in which such special aid as may be given by a diagnostic hospital can be of real help. Instruction in what not to do is one of the important functions of this hospital.

Hospitals, especially in large cities, are frequently subjected to the criticism that their staffs are too restricted, or the reverse. If the restrictions are made too rigid in an attempt to maintain the highest standards of work, many physicians complain that they receive little or no help from the hospital, since they are permitted no satisfactory approach to the advantages which the institution has to offer. If, however, physicians are indiscriminately permitted on the staff, the quality of the hospital work must suffer.

We have attempted to meet this problem by permitting all licensed physicians free access to our facilities, but in the hospital the responsibility for diagnosis rests with a relatively small, full-time and specially trained staff. In this manner, a uniform and high standard of work can be maintained, which is directly available to all physicians and through them to all patients, whether they can pay at full rates, at reduced rates, or nothing, and whether they come from Massachusetts, Maine or some other part of New England.

#### HOSPITAL EXTENSION SERVICES

Experience has shown that in order to reach effectively the hospitals of small communities, an intermediary, large, central hospital within a given

wide area is of great benefit. Working directly from an area like Boston to a small community in Maine involves going over the heads of large hospitals such as the Maine General Hospital in Portland, the Central Maine General Hospital in Lewiston and the Eastern Maine General Hospital in Bangor. A system of direct co-operation between a large center, such as Boston, and a small community in another state also has the disadvantage of a certain amount of awkwardness inherent in the problem of widely separated localities. Quick and ready co-operation between such widely separated points becomes difficult. On the other hand, with the establishment of intermediary centers within the state in question, this difficulty is overcome. We have, therefore, as already indicated, set up a direct line of activity from Boston through regional centers to the small community hospitals within easy reach of them. Such a plan, since it tends to bring into a single working scheme the centers of varying sizes within the state, also avoids the fault of setting up justifiable antagonism by those connected with the larger centers—antagonisms that might develop should direct approach be made from an outside metropolitan center to the small communities. In general, where there has been an active desire to aid small communities, the assistance of larger but more or less local centers has not been sufficiently utilized.

The manner in which these hospitals of various sizes become effective co-operating units can best be described by a brief résumé of our present program of extension services in the fields of laboratory work, radiology, pathology, electrocardiography, dietetics and library assistance.

Technicians in small community hospitals generally work without supervision and have no stimulating contacts in their own field of work. Under these circumstances, and after long-continued isolation, it is only natural that the quality of their work should suffer, and obviously they are not likely to be well informed concerning constantly developing new tests and methods. Designed to meet this need, our laboratory program operates as follows. The technician in each community hospital spends one month of each year in the Central Maine General Hospital in Lewiston, performing routine laboratory duties under the active supervision of a full-time pathologist. Another month each year is spent in the laboratories of the Tufts College Medical School and New England Medical Center, where instruction is given in new methods and procedures, and where technique is further improved. It thus becomes possible for the community hospitals affiliated in our program to employ the newest laboratory tests and technique.

Unquestionably, a short period of postgraduate study can be very stimulating and informative. However, if there is no continued contact between the student and the teaching institution, it is inevitable that the former soon drifts back to his previous habits of thought and action. This is especially true when, as so often happens, postgraduate instruction serves simply to emphasize the inadequacies of the student's local facilities for practice, inadequacies about which he can do nothing. Factual medical information is so vast that the acquiring of a few facts in a short period can hardly be of great value. Such static training is as evanescent as the very "facts" which it imparts.

This situation, which represents one of the defects in the program of most teaching institutions, may be regarded as one of the fundamental factors to be taken into consideration in the planning of any program of postgraduate instruction. The program must provide for "dynamic" instruction which means essentially repeated and continued instruction. Postgraduate instruction is thought to be necessary for the very reason that medical knowledge is not stationary, and that the training acquired in the medical school constitutes little more than a preliminary grounding in the principles of medicine and in habits of thought. A single or occasional postgraduate course would have the same inherent defects, and more strikingly so, as has the regular course in medicine each would offer only a temporary and fixed picture of medicine, when as a matter of fact the problems of medicine are notably neither temporary nor fixed. In the planning of our program, this factor has been duly considered, as already indicated, and it is our purpose more and more to increase the opportunities for continual instruction.

A second basic fact to be considered in planning postgraduate instruction in a teaching institution, a fact which has also too often been disregarded, is that the attitude of the practicing physician toward an institution of learning is entirely different from that of an undergraduate. The latter is forced willfully to apply himself to an intensive program of education, else he must abandon his profession and his choice of a means of livelihood. Under these circumstances, he must study, because he must pass certain requirements. The practitioner, on the other hand, is not so unhappily situated. Only his own desire for knowledge prompts him to take advantage of opportunities for postgraduate instruction and once he becomes a postgraduate student, only the intensity of this desire will influence the serious-

ness with which he applies himself to a period of self-improvement.

Apparently, there are relatively few who are inherently eager for education except as a means to an end, and where no strong outside stimulus exists, a large number of practitioners cannot be expected to seek instruction of a more general character, by this is meant instruction which does not directly and obviously lead to new opportunities for increasing revenue from practice. A physician may, for example, spend a week taking a course in electrocardiography in preference to a general course in cardiology, because the former offers a more definite means of earning money than does the latter. The desire to better oneself financially is probably at least as strong and as widespread as the urge for educational improvement. The economic is at least as great as the moral drive.

So long as a physician's livelihood depends on the practice of medicine, just so long will financial considerations play a part in many aspects of his work. This is inevitable and cannot be condemned, unless the practitioner is freed from financial cares. This fact must be recognized and its implications used as a guide to the practical arrangement of work.

At this point, it may be well to direct attention to certain other problems which arise when teaching of practicing physicians is done, as is so often the case, in an institution where the primary emphasis is on the routine care of cases, the secondary emphasis on instruction for undergraduates, and the least emphasis on instruction for postgraduates. Too often graduates are made to feel that their courses are comparatively unimportant so far as the school or hospital is concerned, and they may leave as much strangers to the institution and with as little knowledge of it as when they arrived. This situation we have made a sincere effort to overcome. We have arranged the postgraduate student's work so that it is integrated with that of the institution. He becomes a part of our organization and is so treated by the staff and instructors. Under such conditions, we have found that our approach is decidedly easier and more effective. This feature of our teaching is now even more pronounced, since the postgraduate students live in the resident quarters on the hospital grounds.

In addition to making the postgraduate student throughout his stay with us an important and integral part of our organization, we have emphasized, as an aid to more effective teaching, an informal approach. During only one hour of the daily eight-hour schedule is he subjected to a for-

the subsidiary center, it would be necessary to alter our present arrangements only so far as they concern the x-ray program. In fact, such a modified plan is at present being developed in Bangor, where the Eastern Maine General Hospital will serve as the regional center to several affiliated hospitals in northern Maine.

It is clear that the medical-school-hospital center is utilized only to the extent to which it can give special aid to the regional center and community hospital. For example, by employing the professor of pathology at Tufts College Medical School only in cases where his special knowledge is required, we can supply to each of the six community hospitals around Lewiston the fullest benefit of his experience, yet in the course of a year he would be required to devote no more time to the Lewiston and the six community hospitals than would be demanded were he to offer a full service to only one of them. Where the community hospitals have had no pathologist because they could not afford one, they now have, in effect, two—in Lewiston and in Boston. And whereas the pathologist in the regional center has had less work than he could comfortably handle, and unsatisfactory opportunities for the stimulating association with an academic center, he now has greater material to work with and regular channels for academic contacts. To the extent that the regional center can carry on its own work, therefore, it is given the fullest stimulation and help.

The program is intended to make possible more and better medical work by physicians in smaller communities. It is not intended to stimulate these physicians to send more patients to metropolitan centers. As an example, instead of urging that a patient on whom an electrocardiogram might be desired be sent from a small community to a large center where such a tracing could be better interpreted, we urge that electrocardiograms be made in the small communities, but under conditions that compare favorably with those in the large center. It is our purpose, in the case of community hospitals, not to take over their activities, but to make it possible for them to utilize more effectively what services they already offer and to supply additional services under the most favorable circumstances.

#### POSTGRADUATE INSTRUCTION

It is clear that a program which offers opportunities for the fullest effective utilization of technical facilities of hospitals of various sizes and does nothing to make possible the intelligent utilization of those facilities by the physicians is unbalanced. Hence the obvious need for postgraduate

instruction to practicing physicians, which naturally represents a major aspect of our undertaking.

The ultimate adequacy of the medical care which can be made available to the majority of the people of this country will be a measure of the adequacy of the physician who administers that care, namely the general practitioner. All plans, therefore, aiming to provide the best medical care should concern themselves with the problem of improving the capabilities and the adequacy of those who are to supply that care, namely with postgraduate education.

The problems of graduate and postgraduate instruction have received much attention, both here and abroad. As applied to practicing physicians, such instruction in general concerns itself with the training of specialists or the giving of "refresher" courses for general practitioners. Our present interest is confined to the latter type of instruction, and more particularly as concerns practitioners in relatively small communities. To such physicians, instruction may be supplied through meetings which they organize and conduct, clinics conducted by well-qualified guest physicians (medical society meetings may also be placed in this category), and courses given in a recognized academic institution.

Our experience indicates that a well rounded program should include some of each of these forms of instruction, since no one alone appears self-sufficient and satisfying. Unquestionably, each has real value. In addition to offering aid in the first two kinds of instruction, as a result of which we are enabled to maintain continued academic contact with most of our postgraduate students, we have for several years given at the New England Medical Center, through Tufts College Medical School, courses of one month's duration covering the general aspects of medicine. The course is specifically designed for general practitioners. During the past year, courses have been instituted in obstetrics and gynecology and in pediatrics. These also are of one month's duration.

Because it is recognized by the Bingham Associates Fund that the burden of the cost of postgraduate instruction is too great for many general practitioners, fellowships are offered for the one month courses at the New England Medical Center, carrying a stipendium of \$250, and there is no tuition fee. These fellowships have as yet been offered only in Maine. In addition, shorter courses of one week's duration are now given in such more limited fields as allergy, gastroenterology, endocrinology and cardiology. For these, no tuition fee is charged to the physicians of Maine, to other physicians, the charge is nominal.

Unquestionably, a short period of postgraduate study can be very stimulating and informative. However, if there is no continued contact between the student and the teaching institution, it is inevitable that the former soon drifts back to his previous habits of thought and action. This is especially true when, as so often happens, postgraduate instruction serves simply to emphasize the inadequacies of the student's local facilities for practice, inadequacies about which he can do nothing. Factual medical information is so vast that the acquiring of a few facts in a short period can hardly be of great value. Such static training is as evanescent as the very "facts" which it imparts.

This situation, which represents one of the defects in the program of most teaching institutions, may be regarded as one of the fundamental factors to be taken into consideration in the planning of any program of postgraduate instruction. For these, no tuition fee is charged to the physicians of Maine, to other physicians, the charge is nominal.

is unquestionably due to lack of faith in the existing medical facilities in the former. If a patient living in a small community knew that local facilities were adequate for taking care of most of his illnesses, and that, on such rare occasions when his condition demanded special attention, he would more or less automatically be sent to an affiliated institution functioning solely to handle such problems, he would be less tempted to leave his community for medical help, except when it was really necessary, and then only at the suggestion of his family doctor.

There is an unfortunate tendency for patients, especially in large communities, to lose sight of the great importance to themselves of having a physician who can serve in the traditional capacity of a true family doctor. In general, the benefits to the patient which result from a patient-and-family-doctor relation are the greatest of all medical benefits. It is only through this association that the conditioning effects of background and environment can be fully evaluated. The family doctor knows his patient as no other doctor knows him. It is he who should decide when a specialist is to be consulted, or whether it is necessary or desirable for the patient to leave home for medical care.

When in the not too dispassionate discussions of medical economics, today, reference is made to the great importance of maintaining the patient-doctor relation, what we really have in mind is that between the patient and the family doctor. That of a patient to a specialist or a full-time clinic or hospital physician can, at best, never be very personal or fully satisfying, in the sense that the relation of such a patient to a family doctor can be. Every patient should have a medical base, through which all his medical benefits derive, and that base should be the family doctor. A patient with no attachment to such a base is needlessly, and often dangerously, stranded. This important fact has been given prime consideration in the development of our program, a program which, recognizing that the fundamental basis of all medical practice is the patient-and-family-doctor relation, is designed to strengthen it and make it more effective.

In the foregoing there have been presented certain general principles, as well as the initial details

of development in their direction. It is to be emphasized that the entire program of development has purposely been left very flexible. The scope of the work is being gradually broadened and extended only as it appears to meet the needs and desires of those concerned. Individuals and local situations are given the greatest possible consideration. Practicable suggestions are constantly welcomed and developed. Everyone concerned, being under no obligation whatsoever, is free at any time to accept or reject whatever he pleases. New steps are taken only when there is assured and mutual co-operation. On such principles rests the development of the program. To such purposes is the new Joseph H Pratt Diagnostic Hospital dedicated.

#### SUMMARY

The Joseph H Pratt Diagnostic Hospital is intended to further the medical program of the Bingham Associates Fund. An attempt is made to describe in a general manner the present status of the work of the Bingham Associates Fund, through the New England Medical Center, in the extension of medical benefits to small communities, and to indicate the direction of further progress.

At present the work is divided into three main divisions: diagnostic aid, hospital extension services and postgraduate education.

The plan is broadly designed to extend into small communities the medical advantages of a metropolitan center by direct and indirect contacts between these elements, arranged on a permanent working basis. The indirect contacts are through strategically located regional centers. It is intended that the communities concerned maintain full opportunities for independent work, but that this work be integrated with that of the metropolitan and regional centers. In this manner it is hoped that there will be established regular and directed channels for the quick and effective passage of medical developments from large medical centers to small communities.

mal or didactic presentation. Informal teaching is possible only with small groups, hence our courses are limited to six physicians. Because of the natural variability of special interests, we have allowed for some degree of flexibility in subject matter. We believe it will be possible to bring about a more or less automatic state of continual education for most, if not all, of the physicians attached as staff members to the affiliated hospitals.

A postgraduate program, such as is being developed at the Joseph H. Pratt Diagnostic Hospital through Tufts College Medical School, seems particularly purposeful, being, as it is, continuous and progressive, and emanating from a source with which a permanent attachment is established locally through community hospitals, and centrally through a clinical medium for the management of difficult problems. The whole exists primarily for the benefit of the general practitioner, who may, if he wishes, use it as his own for the purpose of making available to himself, in a continuous manner, more opportunities to practice better medicine.

The final approach to the general practitioner is through his community hospital, which serves as the local base for this broad educational program. Without such a base, the educational approach from a school to the physician is beset with all sorts of difficulties, particularly as regards the establishment of a self-perpetuating and permanently functioning program.

#### GENERAL DISCUSSION

The scientific and technical advances of modern medicine, because they demand specialization and elaborate equipment, are by and large effectively applicable only through hospital or clinic facilities. Herein lies the basis for the development of so-called group practice, which is essentially clinic practice. It is our opinion that, at least so far as the general practitioner in a small community is concerned, the soundest basis for handling the needs which have given rise to the demand for group practice is a community hospital. With the opportunity to utilize, when necessary, a well-equipped and adequately functioning community hospital, the informed general practitioner can give entirely satisfactory medical care to most of his patients. If, in addition, he has facilities for easy access to help when, again, through being well informed he recognizes the need for such help, he can truly be said to be able to offer to his patients the most complete and the best available medical care. Hence the necessity for an educational program, so that the physician will be well informed, the hospital extension service, so that his hospital will function adequately, and

graded medical centers, for the handling of special problems.

There remains the problem of supplying adequately equipped hospitals. This we are financially unable to do, but we are encouraged by the fact that poorly equipped hospitals are often willing to improve their physical equipment if they are given the opportunity to make good use of these improvements. Thus, when the electrocardiographic service was offered, several of the affiliated hospitals bought electrocardiographs, and when the laboratory service was offered, several arranged to set up extremely well-equipped laboratories, whereas previously they had had practically no equipment.

Incidentally, as the hospitals of various sizes themselves are enabled to do more and better work their income can be expected to increase. When the Rumford Community Hospital can have an electrocardiogram made, or a special x-ray procedure carried out, on a patient who previously would have had to be sent some distance for such work, this hospital can expect to receive for this work the money which, also, would have gone elsewhere. For this reason, at least some of the program of hospital extension activities can be expected to be self-supporting. At present, the complete program is being almost entirely subsidized by the Bingham Associates Fund.

The hospital extension services are a natural development of the postgraduate teaching program. These services were begun after it became evident that in order to make postgraduate instruction more worth while, the physicians must utilize, in their own community hospitals, diagnostic and therapeutic aids which had been demonstrated as being valuable. Postgraduate instruction is incomplete if physicians are taught how to apply intelligently and utilize such aids, and then left with no means for securing them. In following treatment with sulfanilamide there would be no advantage in giving instruction as to the value of estimating the level of this drug in the blood unless facilities were made available in the postgraduate student's local community for such determinations. Our purpose is to make it possible for physicians practicing in small communities to be able to make more valuable their period of postgraduate study at the New England Medical Center by making locally available to them facilities which were of demonstrated practical value. Their own community hospitals can thus serve to continue the benefits of their instruction.

It is natural to want to be near one's home and family when one is sick. The fact that there has developed a tendency for patients to go from small communities to large centers for medical attention

were granted parole privileges. Improvements in this group were generally monosymptomatic or affected only very few symptoms, for example, activity disturbances such as excitement or stupor might disappear, hallucinatory experiences might become less vivid and as a consequence less harassing to the patient, delusions might show some change, although this was not frequently observed in patients in this group. Generally the ameliorated institutional adjustment was such that the patient became capable of doing some productive work, which had formerly not been the case.

D *No change*

E *Aggravation of symptoms* In this group, activity disturbances supervened and were so severe that institutional adjustment became quite poor. All these patients manifested excitements which necessitated sedation and other measures of restraint.

In Table 1 there is presented the outcome for all cases six months after treatment, and also the outcome by sex. It may be seen from this table

TABLE 1 Outcome after Six Months for All Cases and According to Sex

that 21 patients (14 per cent) manifested complete remissions, and 9 (6 per cent) were much improved. The remaining 116 patients (80 per cent) showed some improvement, no change or became worse. Thirty patients (21 per cent) had been

patients (108), but there is some indication that the former may do somewhat better. No statistical validity, however, is attached to this observation.

A remission rate of 14 per cent under treatment in schizophrenia does not seem at first glance to be of any significance. The spontaneous remission rate is approximately this figure, and by some investigators has been shown to be even slightly higher. However, when one considers the large number of chronic patients in this series, the efficacy of Metrazol treatment in the determination of the remission and improvement rate seems to be greater than might have been expected if the patients were untreated. (This point is made clear in a consideration of Tables 4 and 5.)

In Table 2 the therapeutic outcome after six months as related to the type of schizophrenia is presented. It is shown that in the group there were 31 paranoids, 50 hebephrenics, 40 catatonics, 20 patients of "other types," and 5 classified as "simple." Of the catatonic group 20 per cent manifested complete remission and of the paranoid 13 per cent. The hebephrenics had a 10 per cent remission rate and "other types" 15 per cent. From a statistical standpoint it must be stated that no differentiation of the results of therapy in these types can be observed. In this series the catatonic patients have an average duration of illness which is shorter than that of the paranoids. Since it will be shown here that the shorter the illness the better the outcome, the differences between the catatonics and the others cannot be considered significant purely on the basis of type. Furthermore, the number of cases in each group is not large enough to permit ascribing differences in outcome to type to the exclusion of other factors, for example the duration of illness.

In Table 3 the outcome as related to the patient's age is presented. It seems clear from this table that the outcome is better if the patient is

given one or more additional courses of treatment during this six-month period, and 3 had died.

The therapeutic outcome by sex was as follows. The small number of men patients (38) cannot be adequately compared with the number of women

under thirty (remission rate 21 per cent) than if he is older, but that a fair number of remissions (14 per cent) are possible in the age range of thirty to forty. In the age range of forty to fifty the outcome must be considered much more pes-

# FACTORS INVOLVED IN THE STABILITY OF THE THERAPEUTIC EFFECT IN THE METRAZOL TREATMENT OF SCHIZOPHRENIA\*

Report of 146 Cases

LOUIS H COHEN, M D†

WORCESTER, MASSACHUSETTS

FROM the data already available in the literature the significance of various factors involved in the determination of the efficacy of Metrazol treatment in schizophrenia has been pointed out. In general it has been found that the shorter the illness and the younger the patient the more likely he is to benefit by treatment<sup>4-6</sup>. There is some evidence also that the type of schizophrenia may be significant in this respect. The catatonic and the paranoid-hallucinatory types are more favorably affected than is the hebephrenic.<sup>6</sup> It is the purpose of this report to present further data concerning these variables and to indicate the significance of some factors in the prognosis after treatment has ceased.

The following data are based on observations made on 146 schizophrenic patients. Of these, 38 were men and 108 were women. None of the patients showed evidence of any physical disease. Each patient was treated with Metrazol in the same fashion. The initial dose was 3 cc of 10 per cent Metrazol (Bilhuber-Knoll). All injections were intravenous. Treatment was administered daily, the dose being increased by 1 cc until a convulsive threshold was reached and thereafter maintained at that level. Preliminary hydration and alkalization were not carried out, these having now been shown to be unnecessary.<sup>1, 2</sup> Treatment was discontinued when further improvement seemed improbable. This is admittedly an arbitrary criterion which rests entirely upon clinical judgment, however, there are no data available as yet which prove what the optimal number of seizures may be for schizophrenics as a group nor what factors must be considered in the determination of individual variations in this respect. In some of the patients repeated courses of treatment were necessary, as will be shown in the tables.

The clinical status for each patient was rated at specific time intervals after the cessation of treatment. Judgments were made at the end of treatment, and two weeks, one month, two months, four months and six months later. For many of the patients data are available for periods over a year, but in order to have a sufficient number of cases upon which to base conclusions the present

report is not concerned with outcome beyond the six-month period following treatment. Only the outcome after six months will be presented, since data with regard to shorter periods are already extensively available and do not appear to contribute very much to the elucidation of the problem.

## RESULTS

Data are presented covering the therapeutic outcome for all cases six months after treatment, the significance of sex differences, of differences due to the diagnostic types of the disease, of differences due to the patient's age, of differences due to the duration of hospitalization and of differences due to the duration of illness, and finally a comparison of the outcome after six months with that after one month.

Therapeutic outcome was judged and classified under five headings as follows:

**A Complete remission** Remission was considered to consist of complete freedom from all symptoms, the ability of the patient to leave the hospital and resume his former occupation and the absence of any observable peculiarities. In other words, the patient's condition was considered to be that of a full remission only if he again became the same person, so far as could be recognized, as he had been before his illness.

**B Marked improvement** In this group, symptoms had disappeared almost entirely, residual symptoms being such that they did not interfere with an adequate social adjustment. For example, a patient who manifested some shallowness of affect or relatively inconspicuous mannerisms would be considered to have shown much improvement if his condition were such that he could go home, or enjoy full parole privileges. The continued presence of hallucinations, delusions or severe activity disturbances would exclude any patient from this group, however much improvement might occur in his social adjustment in the hospital.

**C Some improvement** In this group were patients in whom such modification of symptomatology occurred that a better institutional adjustment became possible. In no case were these patients well enough to go home, although some

†Senior research psychiatrist, Research Service, Worcester State Hospital.

tained this status without change but the rest (69 per cent) had relapsed. Of the 31 patients who had shown no change, 1 achieved a complete remission and 2 showed slight improvement, but 90 per cent had not changed their status. It is of interest that of the 3 patients who were worse one month after treatment 2 improved without re-treatment. On the basis of this sample it would appear, therefore, that the patient's outcome six months after cessation of treatment may be predicted from his outcome one month after treatment, if he has achieved full remission, his chances

gloomy. The fact seems clear that if the patient becomes completely well after treatment his chances of remaining well are excellent, and it is only by the criterion of full remission that the potency of Metrazol, with respect to the stability of improvement, can be measured.

#### SUMMARY AND CONCLUSION

Data have been presented on the therapeutic outcome after six months in 146 schizophrenic patients in whom daily treatment with Metrazol had been carried out. It was shown, as others have

TABLE 6 Outcome One Month after Treatment as Compared with That Six Months after Treatment

SIX MONTH RATING	A		B		C		D		E

of remaining well are great (in our sample, 89 per cent), but if he has fallen short of full remission the chances of maintaining his improvement are relatively small (in our sample, 30 per cent). The conclusions may therefore be drawn that in the evaluation of Metrazol therapy one must consider that only those patients who become *completely* well will so continue, and that patients who do not become completely well have only a third as good a chance of retaining even the considerable improvement which they may have manifested immediately after cessation of treatment.\*

The data of Table 6 may lend support to some general considerations concerning the nature of the schizophrenic process. It appears from these data that in most cases recovery can be maintained only if the schizophrenic symptoms can be removed in toto. Conversely, if there remain any residual symptoms the probability of relapse is high. These statements may indicate that the schizophrenic disease process is an "infiltrating" one, analogous, perhaps, to neoplastic processes. One might push the analogy further and suggest that in the early stages the process may be relatively benign and with treatment can be effectively removed from the personality, but that when malignancy of the nature of personality infiltration has occurred, the outcome is

pointed out, that therapeutic results are better in young patients with a short hospital age and a brief duration of illness. Differences due to diagnostic type or to sex could not be demonstrated. It was found that the stability of the therapeutic effect, as compared one month and six months after cessation of treatment, depended largely on whether full remission had occurred. For those patients who achieved full remission, 89 per cent remained in this fortunate state after six months. On the other hand, of those patients who had shown much or slight improvement after one month, only 30 per cent retained the improvement after six months. The conclusion may therefore be drawn that anything short of a full remission must be considered pessimistically, so far as this therapy is concerned, with respect to ultimate clinical status, although amelioration of the patient's institutional adjustment may, in about one third of the cases, be expected to persist.

greater support is lent to this suggestion In this table it may be seen that only 22 patients (15 per cent in all) had been ill less than one year, the remission rate for this group is 59 per cent Although data on spontaneous remission rates are not available for patients who have been ill less than one year, I am of the opinion that a figure of 59 per cent is well above that which might be expected for this group

The above tables show generally what has previously been observed by other investigators, namely that the shorter the duration of illness, and, concomitantly, the younger the patient and the shorter his hospital age, the better, is the therapeutic outcome with Metrazol treatment

The question arises as to what prognostic opinion may be attached to given patients after the cessation of treatment It is a common practice, for example, for investigators in this field to state frankly to the patient's relatives that although the immediate change might be beneficial, how long it will last is another question The following data throw some light upon this question In Table 6 there are presented data which compare the patient's status six months after the cessation of treatment with that one month after the cessation of treatment The status one month after the cessation of treatment rather than immediately afterward has been taken in order to eliminate cases with short-lived changes, and also to include patients whose condition may improve within the first month after cessation of treatment

Several facts stand out in this table The most striking seems to be that of the 18 patients who underwent complete remission, 16 (89 per cent) enjoyed this status six months later Of the 40 patients who had shown much improvement, 4 attained complete remission and 8 maintained their improvement, largely due to the fact that most of these patients had had subsequent courses

come as related to these variables must be considered These data are presented in Tables 4 and 5, which should be studied together with Table 3 in the evaluation of Table 1 shown above

As was indicated in the discussion of Table 1, a remission rate of 14 per cent for all cases after six months was found In Table 4 one may observe that the remission rate is 37 per cent in patients who had been hospitalized less than one year, 7 per cent in patients hospitalized one or two years, and none in patients who had been hospitalized for longer periods On the other hand, of the entire group only 51 patients (35 per cent) had

been hospitalized less than one year The lowness of the remission rate for all cases may therefore be ascribed in part to the prevalence of cases with a high hospital age Furthermore, when these data are considered together with those of Table 5,

of treatment These 12 patients comprise only 30 per cent of the B group, hence of the 40 patients who had shown much improvement, 70 per cent had relapsed Of the 54 patients who had shown some improvement, 17 (31 per cent) had main

matters die in committee Under this procedure, a bill never sees the light of day unless a committee selects it as one on which they wish to make a report The same procedure is followed in Congress But in Massachusetts, when prorogation takes place, every measure must have been reported upon

There are a number of technical reports a committee can make, but in the main they fall into one of two classes—favorable or unfavorable

If a petition, accompanied by a bill or resolve is reported adversely by a committee, it is placed on the calendar in the branch in which it was reported and any member has the privilege of moving substitution of the bill or resolve and of getting a roll-call vote on it, providing he can get thirty members to join in the request If the petition is rejected in one branch, it must go to the other branch for concurrence in that rejection

If a bill or resolve is reported favorably by a committee on a petition referred to it, the measure is first read in the branch to which it is reported, and this is called the First Reading of the bill or resolve Unless this matter is one that requires reference to some other committee,—such as the Committee on Ways and Means or the Committee on Counties, because it provides for the expenditure of state money or is a county matter,—it is placed in the orders of the day for the next legislative day, without debate, for a second reading At this stage it is debatable, and can be amended or rejected If rejected, being a bill, it is dead, and does not go to the other branch If ordered to a third reading, it is referred to the Committee on Bills in the Third Reading of that branch This committee is a highly technical one and has a staff of legal experts attached to it Its sole function is to see that the bill has been “correctly drawn,” that is, that its provisions are not unconstitutional and that its legal phraseology is correct, and to redraft it, if necessary, in such a way that it will fit into the form of the General Laws The only report that this committee can make is that the bill has been correctly drawn, or to suggest an amendment in order to clarify the wording, and if it sees fit it can recommend that it ought not to pass In other words, it cannot make substantive changes

When the report of the Committee on Bills in the Third Reading appears on the calendar, the question before the branch considering it is, Shall the bill be passed to be engrossed? At this stage it can again be amended or rejected entirely, and if it is, it does not go to the other branch If the measure is passed to be engrossed, it is held one day so that any member may exercise his right to ask for reconsideration, and it is then sent to the second

branch, where, after its first reading, it takes the same course that it took in the first branch

If the second branch amends the bill in any particular, it is returned to the first branch for concurrence in the amendments If it substitutes a new bill, that bill is sent to the first branch and it goes through the same process as if it never had been considered by it, namely three readings If the two branches do not agree in the amendments made, and neither will recede from its decision, a committee of conference is appointed as in other cases of disagreement, and its recommendations are usually accepted If the branches still cannot agree another committee on conference may be appointed, but usually not more than three such committees are appointed, and the measure, for want of agreement, dies between the branches

After a bill has been passed to be engrossed in both branches, it is sent to the Secretary of State's office and is engrossed on parchment paper with a special typewriter This copy must be accurate, as it is the authentic document, which is reported to be “rightly and truly engrossed” by the Committee on Engrossed Bills

The bill is then enacted, first in the House, and then in the Senate after which it is sent to the Governor Under the Constitution, the Governor is allowed five days to act on the measure If he signs a bill involving general legislation, it becomes law in ninety days, under the provisions of the constitutional amendment regarding the initiative and referendum unless it has an emergency preamble, when it takes effect at once If the Governor takes no action within five days, the bill becomes a law automatically, but he may veto a bill by returning it to either branch with his objections, and if two thirds of the members of both branches vote to override his veto the bill becomes law, notwithstanding his objections

The House and Senate journals record every stage of action by both branches on a petition for legislation up to and including the moment it receives the signature of the Governor

This, briefly, is the procedure followed with regard to proposals for legislation to the General Court

From the point of view of the layman, this procedure is important Unless rules are suspended for an emergency, from two to three weeks are required, after a committee has reported on a measure, for it to get to the Governor's desk During this period of time popular sentiment can be aroused either for or against the measure.

There are differences of opinion as to what in-

## LEGISLATIVE PROCEDURE\*

CHRISTIAN A. HERTER†

BOSTON

THE Massachusetts legislature and that of Iceland are the only two truly democratic legislatures left in the world. The Massachusetts Legislature used to be called the "Great and General Court for the Redress of the Grievances of the Common People." It is now called the "General Court," and while it has never been known as such in the literal sense, it has always been thought of as a court which sits in public to listen to grievances and to remedy them, through the enactment of legislation. Hence the use of the more common name, the Legislature.

Our procedure is very different from that of other states in that it contains the elements of true democracy that none of the others have. For example we have the constitutional right of free petition, which guarantees to every citizen the right to draft and sign a petition, accompany it by a bill, resolve or resolution explaining the legislation sought, no matter how ridiculous, and have it presented to the Legislature by requesting a representative or senator to place his name on the back of the petition blank. The legislator, however, can indicate that he personally does not necessarily sponsor the provisions of the measure, by adding after his name the words "by request."

The number of petitions presented every year, considering this tremendous leeway, is small, but even a small number consumes a great amount of time when one considers the many channels through which, under the rules, a measure must pass and the careful scrutiny it receives before it is enacted into law. This year, we have before the General Court the largest number of measures ever filed—approximately twenty-five hundred, this number includes state departmental reports with recommendations for legislation, and reports of about twenty legislative recess commissions, representing studies made during the recess of last year. Under the rules, all proposals for legislation are required to be filed on or before the second Saturday following the date of convening of the session.

A petition for legislation, after being presented to the legislative clerks, is referred by them to a committee, subject to the approval of the presiding officers of both branches. There are twenty-nine joint standing committees which are appointed by the president of the Senate and the

speaker of the House. The petition is then assigned a date for a public hearing, and a clerk sends a postcard notice to the legislator who introduced the measure and to the petitioner seeking the legislation and to anyone who has requested a notice. A large amount of money has been saved in recent years by discarding the custom of the wholesale advertising in the newspapers of the date of a hearing on a petition. The rules state that when a petitioner can be reached by written notice, no such advertising shall be used. It is important that anyone who has any interest in a pending petition should notify the clerk of the committee to which it has been referred at an early date so that he may be notified of the hearing date.

The *Legislative Bulletin* publishes a list of all matters as they are referred to committees, showing the number and title of the petition and the date of the hearing. This bulletin later carries the action of the committee, an index of all matters referred to committees and a running record of what happened to each measure at every stage of its progress through the House and Senate, action by the Governor and the chapter number assigned if it becomes a law.

The bill, resolve or resolution accompanying the petition or the report is printed. Under the rules, nine hundred copies of each measure are printed for the use of the Legislature, and copies may be obtained by the public at the Legislative Document Room on the fourth floor of the State House.

At the public hearing, the committee usually hears persons in favor of a proposal first, and those in opposition afterward. Some hearings have been known to last over a period of six weeks, as in the case of a proposal to remove a judge, while others last only a few minutes. As a general rule petitioners are allowed ample opportunity to present their case, it being the function of the committee to give a fair, adequate and complete hearing to all who are interested in the measure.

After the hearing on a measure has been completed, the committee goes into executive session to determine what recommendation it will make to the Legislature with reference to the disposition of the petition, or other subject of legislation. The sessions of almost all other legislatures are limited to sixty or ninety days. In such states, they may pigeonhole or table proposals for legislation, or let

\*An address given at the annual meeting of the Massachusetts Central Health Council Boston February 16 1939

†Speaker of the Massachusetts House of Representatives

of the chest. Signs of inactive tuberculous chest lesions were found in 2 cases. One of these patients had also had a tuberculous kidney removed. One patient had a tuberculous prostate, with a urinary fistula located just above the pubic bone. A fifth case, which was treated here for disease of the symphysis pubis, is not included in the series, as it was ultimately diagnosed as non-tuberculous because of the repeatedly negative guinea-pig inoculations and Mantoux tests.

#### TREATMENT

The usual treatment in the past was thorough curettage of the infected bone and drainage of any abscesses present, in accordance with the accepted treatment for osteomyelitis. Thus, many of the earlier reports<sup>1</sup> state that the bone was curetted and the wound cleaned and drained. Unfortunately very few reports include follow-up, and the ultimate result of this procedure is not recorded. Bean treated his case with curettage, and in addition laid a bone graft across the horizontal portions of the pubis. The bone ultimately filled in, but the graft was absorbed. The patient improved and her symptoms disappeared. Jackson<sup>2</sup> in 1923 reported a case of tuberculous symphysis pubis in a girl of eleven who had difficulty in walking and then developed an abscess on the right thigh just below Poupert's ligament. She was treated conservatively and followed by x-ray studies for several years and ultimately showed new bone formation in the diseased area.

The first patient (Case 1) seen at this sanatorium was a Negro of forty-seven admitted in August, 1926. A fusion of the symphysis pubis had been performed at another hospital, a tibial graft being used to bridge the diseased area. Following the operation the wound broke down and drained. X-ray films at this institution showed the graft floating in pus. This sequestrum was removed, and the cavity curetted. Most of the operative wound healed, and the patient was eventually discharged with a small pin-point sinus still draining but with his general condition good.

The next case was that of a white man, aged fifty (Case 2). Having had experience with the previous case, and with the widely accepted clinical fact that bone grafts do not attach themselves favorably in a tuberculous field, we decided that a new method of approach was desirable. It occurred to our orthopedic consultant, Dr. Zabdriel B. Adams, that the pubic bones could be splinted by ankylosing both sacroiliac joints, thus steadying the entire bony pelvic ring.

The pelvic ring is made up of the innominate

bones, united in front by the symphysis pubis and joined in back to the sacrum. By elimination of whatever motion may be left at the sacroiliac joints, the motion in the anterior portion is reduced to a minimum. The main advantage of this procedure is that we work in a clean field, whereas the former procedure of curettage and laying down of a bone graft in a diseased field may result in the breaking down of the wound, with resultant formation of sinuses and sequestration of the graft.

This procedure was tried on this patient and also on 2 others, a girl of fifteen (Case 4) and a boy of sixteen. The type of fusion operation is of secondary importance, as the operation is performed in a clean field and on healthy bone, and any type of fusion if efficiently performed will result in ankylosis of the joint. We used both the Smith-Petersen and the Campbell methods.

In Case 4, the fusing of both sacroiliac joints did not at first prove sufficient, and we therefore resorted to the old procedure of curetting the diseased area and laying down a bone graft. Sequestration resulted, and several bone spicules were removed from a suprapubic sinus which developed after the operation. The sinus eventually stopped draining, and the patient was discharged in good condition. She was last seen two years and ten months after her last operation and was in good general condition, free of all symptoms, and with the sinus closed.

#### CASE REPORTS

*Case 1.* C. H. A., a 47-year-old Negro, in 1916 developed an abscess in the left groin. It was incised and drained for 1 week. In 1918 a similar swelling developed in the right groin. It remained the same size until 1926, when it became considerably larger. The patient was admitted to a hospital in Boston, where the abscess was aspirated. X-ray films of the pelvis taken at that time showed a destructive lesion in the symphysis pubis, and an ankylosis operation was performed, using a bone graft from the left tibia. Nine days later the wound broke down and began to drain. The patient was admitted to the Lakeville State Sanatorium on August 2, 1926, because of this discharging sinus. The discharge was profuse and was found positive for tubercle bacilli.

X-ray films of the chest showed several calcified nodes in both hili, with infiltration of both apices. Films of the pubis showed a sequestrum of the former bone graft, floating in a field of pus. This sequestrum, along with several fragments of broken-down and frayed dead bone, was removed from the channel where the graft lay, and the cavity was curetted. Most of the operative wound healed and was reduced to a pin-point size. The patient was discharged a little over 2 years after admission, with the sinus still showing a slight amount of discharge. The last x-ray films before discharge showed beginning bony ankylosis of the symphysis pubis and increased calcium deposit. He was in good general condition and free from local symptoms.

*Case 2.* R. D., a 50-year-old man had had his right

fluences the legislator in making his decision before voting on legislation. The more I have seen of the legislative process, the more I am convinced that outside agencies studying legislative problems and making analyses are responsible for more legislation than are the legislators themselves. It would be absurd to assume that a legislator could vote on twenty-five hundred matters without seeking advice. In most cases, the committee is swayed by individuals whose judgment it respects. Almost all legislative bodies act as a result of the pressure of various forces. There are always proponents and opponents. The legislator is torn between the two, and when, through lack of facts at his disposal, he is incapable of forming an independent decision, he must rely on the judgment as well as the wishes of the district from which he comes.

You hear much about lobbyists. They are a useful group to a legislator. They are, to be sure, hired by some organization. They register themselves, under the rules, as paid lobbyists, and they give the member more real information on a given subject than he could easily get elsewhere. That is their business. They try to give you facts and

if at all experienced as lobbyists, they know that it is dangerous to supply you with wrong data because it will hurt them. It is the lobby group from which the members get more information than from any other. For example, Dr. Blank is a lobbyist. He is registered as representing a definite organization. He is a good lobbyist because of his accurate information and his good judgment. Unfortunately, the term "lobbyist" is applied to everyone who tries to influence legislation. They are not all equally useful. There are a good many different ways of lobbying—that is, different techniques.

You in this organization have much greater strength than you realize. If you appeal to the intelligence of the community in which the individual legislator lives you can exert a tremendous influence, whether you realize it or not. In any man's district, two groups have great influence—the church and the medical and nursing professions. This is because both groups have contacts with many people and have many opportunities for spreading respected word-of-mouth opinion.

State House.

## TUBERCULOSIS OF THE SYMPHYSIS PUBIS

LOUIS ALPERT, MD \*

MIDDLEBORO, MASSACHUSETTS

**T**UBERCULOSIS of the symphysis pubis has been reported on a few occasions in the English literature but more frequently in the foreign journals. However, it is still considered too infrequent to warrant its description in either orthopedic textbooks or systems of medicine.

Bean,<sup>1</sup> of Salem, Massachusetts, in 1930 described a case encountered in his practice and comprehensively reviewed the literature written on this subject up to that time. Practically all the preceding reports appeared in foreign journals. Since then no other reports on this subject have appeared in the English literature although one quite frequently encounters descriptions of injuries and osteomyelitis of the pubic bone. In this paper I shall report 4 cases of tuberculosis of the symphysis pubis, treated at the Lakeville State Sanatorium, describe the commoner symptoms and findings and discuss in detail the operative procedure followed in 2 of the cases, namely surgical fusion of both sacroiliac joints.

The commonest symptoms encountered, according to most authors,<sup>1</sup> are an irregular gait, a tumor mass and pain in the region of the pubis. Many of the earlier reports emphasize an irregular or painful gait as the chief complaint. The chief symptoms our cases presented were pain over the pubis, a tumor mass and backache. The tumor mass appears oftenest in the groin or over the pubis. It is frequently mistaken for a hernia or psoas abscess. X-ray films of the pelvis, whenever this sign occurs, may show irregularity or destruction of the symphysis pubis or pubic bone. If an abscess is present, bacteriological study reveals the nature of the infection.

None of our patients showed an irregular or painful gait, possibly because they were seen earlier and before the destruction became very extensive. The first complaint that 2 patients presented was swelling in the groin, 1 had pain in both groins and 1 first experienced pain in the region of the left hip.

All the patients had routine x-ray films taken

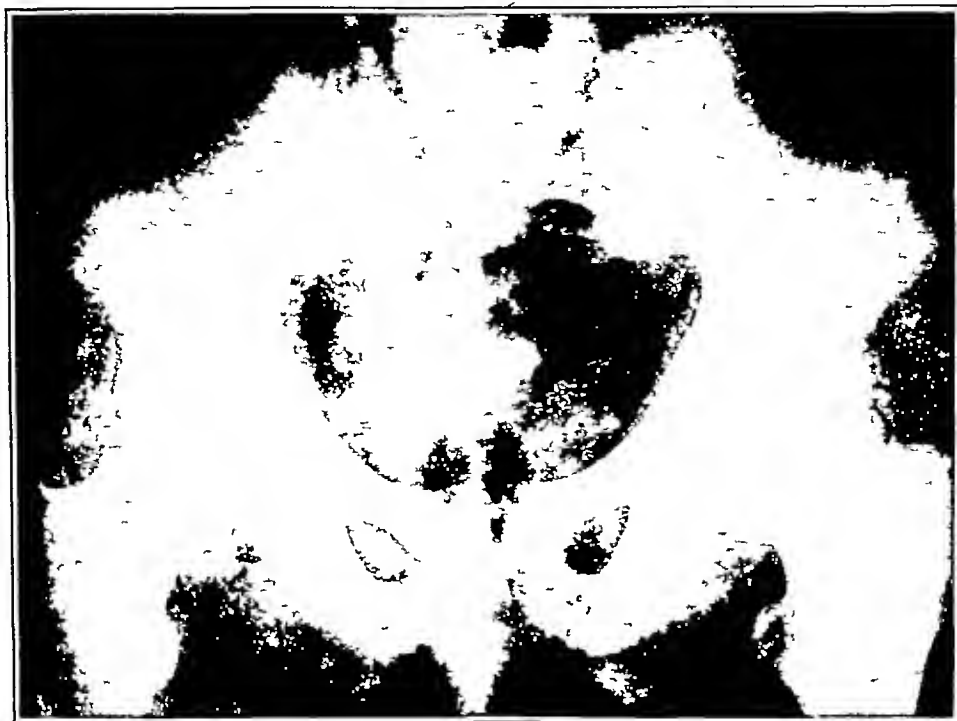

FIGURE 2. Case 2

kidney removed for tuberculosis in January, 1930. At that time he also showed tuberculous infection of the right lung by x-ray study. He was admitted to the Lakeville State Sanatorium on October 18, 1932, because of pain in both groins of 1 year's duration. Examination on admission showed tenderness on deep palpation in both groins. These areas and the region of the symphysis were free from swelling and induration. An x-ray film of the chest showed bilateral apical lesions, and that of the symphysis pubis showed a process in the left pubic bone, apparently inflammatory. In January, 1933, the left sacroiliac joint was fused surgically and in June, 1933, the right sacroiliac joint was similarly fused. The patient made a good

tract and were apparently due to an old duodenal ulcer. The patient remained only 1 month, and during that time was free of pain or symptoms referable to the symphysis pubis. The cold abscess was apparently absorbed. X-ray films at the time of discharge (Fig 2) showed new bone formation with increased calcification and apparent arrest of the destructive process.

*Case 3* B. S. was a 57-year-old white man. When the patient was 5 years of age, in 1881, a sister, aged 16, died of pulmonary tuberculosis. The patient had been in daily contact with her. In 1925 he developed lameness accompanied by swelling in the left groin. This mass broke

FIGURE 1 Case 2

*Note the destruction of left pubic bone, extending into the upper and lower rami*

postoperative recovery, the symptoms disappeared, and he was discharged.

In December, 1933, he developed pain and swelling over the pubic bone, and in March, 1934, he was readmitted. He showed a lump over the pubic bone the size of a small orange. He was treated conservatively, and the mass gradually became smaller. From time to time an old sinus in the left sacroiliac incision would drain for short intervals. An x-ray of the symphysis showed increased destruction, extending well into the pubic bone on the left side (Fig 1). The suprapubic mass became smaller and at the time of discharge, April, 1935, it was still palpable deep over the pubis and about the size of a hen's egg.

The patient was readmitted in December, 1937, because of an old sinus over the left sacroiliac incision, which continued to drain at intervals. A few drops of this material was injected into a guinea pig and was found to be positive for tubercle bacilli. The mass over the pubis, which had been present on the first admission, was absent. Most of the complaints were referable to the gastrointestinal

tract and drained, and another sinus developed over the pubis. The two seemed connected. The sinus was excised, and the pubic bone was curetted. The suprapubic sinus was later found to be connected with the bladder. The sinuses healed and patient remained well for the next 6 years, except for an occasional drop or two of serous exudate from the suprapubic sinus. In September, 1933, a tuberculous prostatic abscess was found, and the patient was sent to the Lakeville State Sanatorium for further treatment. On admission he showed a scar over the pubis, with a sinus draining purulent material and apparently connected with the bladder. Material from this sinus was found positive for tubercle bacilli on guinea pig inoculation. X-ray films of the chest were negative, but those of the pelvis showed complete loss of cartilage in the symphysis pubis, with increased density of the pubic bones and bony fusion of the symphysis (Fig 3). In addition, the patient had a tuberculous prostate and tuberculous epididymes. The lesion in the symphysis was considered arrested, and he was discharged in November, 1933. A

recent contact with this patient found him in good health and at work, but still having occasional discharge from the suprapubic sinus

*Case 4* H. M. W., a 15 year-old white girl, had a negative family history. In 1931 she began to experience pain in the region of the left hip. In 1932, while skating, she fell and the pain became worse. She was taken to a local hospital, where x-ray films showed a lesion in the symphysis pubis, and she was hospitalized for 5 months. In October, 1934, this pain became more severe and persistent, and she was admitted to the Lakeville State Sanatorium in November, 1934. Physical examination was essentially negative, except for tenderness over the left pubic bone and a groove like depression over the symphysis pubis. X-ray films of the chest were negative. Those of the pelvis showed a destructive process involving the symphysis pubis (Fig 4). Both hips were normal. The patient was treated for 3 months with a short double spica and then had both sacroiliac joints fused by the Smith Petersen method. The operations were performed about a month apart. She was allowed up in June, 1935, 1 month after her second operation. While up and about she complained of pain in the region of the pelvis, localized in the right sacroiliac region and radiating down the right thigh. This pain persisted, and it was decided to fuse the symphysis pubis directly. This operation was performed in October, 1935. A graft was removed from the left tibia and fitted into a groove, which was made to extend across both pubic crests. The appearance and contour of the crest at the time of operation suggested bone degeneration in that area.

Shortly after operation an abscess developed in the suprapubic wound, which broke down and drained. Three sinuses resulted, and two small sequestrums were removed from one of them. After various kinds of local treatment the abscess gradually became smaller and the sinuses healed. The patient was again allowed up, and was discharged in December, 1936, with all the sinuses dry and the abscess healed, she was free from pain (Fig 5). She has been followed in the Outpatient Department every 6 months since then, and was last seen in the early part of 1938. She has remained free from pain and walks normally, and the sinuses have remained dry and well healed. Routine x-ray examinations have shown increased calcification, and new bone formation bridging across and connecting both pubic bones.

#### DISCUSSION

The articulation between the pubic bones is an amphiarthrodial joint, formed between the two oval articular surfaces of the bone. Each of these surfaces is covered by a thin layer of hyaline cartilage. These opposed cartilaginous surfaces are connected by an intermediate lamina of fibrocartilage, which varies in thickness in different subjects. It often contains a cavity in its interior, and it is not lined by synovial membrane.<sup>3</sup> The pubic symphysis can be considered as an accessory joint to the pelvis, the most important mechanical function of the latter being to transmit the weight of the trunk and upper limbs to the lower extremities. The ligaments of the symphysis pubis help in resisting the separation of the iliac bones in all rapid movements. During pregnancy the ligaments are relaxed and therefore capable of more

extensive movement. During normal life there may be strain on the symphysis and its ligaments but very little if any motion. When disease affects this area, conditions are altered, and this side of the pelvic ring becomes subject to stress and strain with every twist and turn of the body. The infection destroys the cartilage and proceeds to increase the space between the pubes by destroying the adjoining bone. Figure 4 (Case 4) shows the ramus of the pubic bone on both sides destroyed by the diseased process. Fixation should be used in the early stages to protect the lesion. For complete immobilization we have used the double short plaster spica. When the patient has reached the convalescent stage a tight pelvic belt suffices.

The ultimate result sought in any tuberculous joint involvement, where the process has gone on to bone destruction, is regeneration of the diseased bone with good bony ankylosis of the articulating surfaces. This decreases to a minimum the future stress and strain on the infected tissue, and helps to prevent the reactivation of the disease. Simple curettage in the non-tuberculous infected processes very often suffices, but in acid-fast lesions this is insufficient and the additional use of a bone graft is desirable. However, experience has shown that bone grafts applied directly in a tuberculous field have very little chance of success and more often than not slough out and form sequestrums. This is true of grafts used for a tuberculous symphysis pubis. Thus, we note that in Case 1 the laying of a bone graft across the symphysis resulted in abscess formation, which cleared up only after the dead bone graft, which was found floating in pus, was removed. In Case 4, likewise, following the graft operation the patient developed a small suprapubic abscess with a few sinuses and several spicules of bone were removed.

The surgical fusion of the sacroiliac joints, on the other hand, provides a new approach to this problem. One objection to this procedure may be that we are fusing joints that normally have very little range of motion to begin with. Much has been written and said about the amount of motion present in the sacroiliac joint. Sashin,<sup>4</sup> as a result of an exhaustive study, reported in 1930 that motion in the sacroiliac joint was at best only slight. Pressure of the superimposed body weight, sudden turns or shifts or any sudden change in position subjected the joint surfaces to great trauma. As a result of this constant pounding, early degenerative changes set in which eventually led to ankylosis. His study was based on findings on 257 postmortem examinations. Brooke,<sup>5</sup> examining 200 anatomical specimens, of which 95 were male and 105 female, found that 37 per cent

## CONSERVATIVE OVARIAN SURGERY IN THE HANDLING OF DERMOID CYSTS

ALEXANDER A. LEVI, M.D.\*

BOSTON

THIS paper reports the case of a woman of thirty-three in whom dermoid cysts of both ovaries were found, that on the right involved the entire ovary, and that on the left only a portion of it. The right ovary was removed in toto, the left ovary was partially resected and repaired. This conservative point in the technic, as near as I can determine, is not followed as often as it should be. I am therefore reporting this case because it illustrates a procedure, as related to dermoid cysts, not described in textbooks and rarely suggested in the gynecological literature.

Many authors have written papers in which they condemn the indiscriminate removal of ovaries. Few of them have stressed the fact that dermoid cysts can be partially resected and need not always be completely removed. It certainly seems justifiable to spend the time that is required to perform this type of operation when two facts are considered. The first is that dermoid cysts are recognized most frequently during the childbearing years.<sup>1</sup> This consideration alone calls for conservatism. Secondly, the development of an artificial menopause in a young woman presents a difficult problem.

Bonney<sup>2</sup> and Bell<sup>3-5</sup> in their writings also make such a plea. The latter,<sup>3</sup> in order to emphasize this point, says "To me, and to many others, ovarian conservation is a surgical axiom, and I consider the indiscriminate 'clean-sweep' removal of ovaries—as a routine procedure—a surgical sacrilege." However, to my knowledge, this conservative procedure has not been employed in Boston. I have questioned a large number of prominent surgeons and gynecologists many of whom hold teaching positions of professional rank in local medical schools, and only one had ever performed the procedure here described. This individual stated that his case was a very recent one.

For many years it has apparently been the custom in cases of dermoid cysts for surgeons to remove both ovaries completely when bilaterally involved. In many cases this was not done if the patient was in the childbearing stage of life. In such cases the smaller ovary was permitted to remain intact—a procedure dangerous in itself. If, however, the surgeon feared the consequences of leaving such an ovary, whether or not the patient was in the childbearing stage, both ovaries were removed. This produced an artificial meno-

pause with its varying signs and symptoms, often converted a relatively well patient into who suffered more from the symptoms of the pause than she had ever suffered from the dermoid cyst. It therefore seemed to me advisable to serve whatever normal ovarian tissue might encountered in a case of this sort. This opinion concurred in by a pathologist with whom the technic was discussed some time after the operation. He thought that if normal tissue could be demonstrated there would be no reason for removing

I realize that only scanty conclusions can be drawn from one case, but in spite of this I believe am justified in making this report and the accompanying suggestions, since few references to conservation of ovarian tissues in these cases are found in the literature. In addition, the case question is reported because in the seven months which have passed since the operation the patient has had regular menstrual periods and has had no symptoms referable to the menopause. This least indicates the normal functioning of the portion of ovary that was left in and reconstructed at the time of operation, and therefore seems to justify conservative surgery.

### CASE REPORT

L. A. W., a 33-year-old, unmarried woman, had always been in good health except for some of the contagious illnesses of childhood. She presented herself for a routine physical examination because friends had suggested. Her menstrual periods had begun when she was 12 years old, and occurred regularly every 28 days, lasting 3 to 4 days. On occasion her periods were accompanied by slight pain. The amount of flow was moderate, requiring the use of not more than four or five napkins a day. Her last period had occurred on June 22, 1938.

The physical examination was essentially negative. Vaginal examination could not be performed because of a virgin introitus. Rectal examination, however, disclosed the uterus to be normal in size and position. The right ovary seemed slightly enlarged and tender. The left ovary seemed to be about the size of a closed fist, although filling the right vault. It was not movable, was quite tender and felt tense. A diagnosis of bilateral dermoid cysts was made.

The patient was admitted to the Cambridge Hospital and was operated on July 6, 1938. Exploration of the abdominal cavity disclosed the appendix to be in a retrocecal position, bound down by numerous adhesions and enveloped by a large amount of fat. Only the tip was visible. The uterus was normal in size and position. The right ovary was about the size of a fist. Its capsule was extremely thick, and the ovary lay deep in the pelvis, filling the right vault and posterior cul-de-sac. Numerous hard masses were present near the mid portion of the right

\*Teaching assistant in Department of Gynecology, Tufts College Medical School, senior gynecologist, Cambridge Hospital.

of all male joints were completely immovable and ankylosed. In none of the female specimens was bony ankylosis present. This study also showed that an increase in cases of bony ankylosis corresponded directly to an increase in age.

The fact remains that clinically we are unable to determine whether the sacroiliac joint is ankylosed. That an infected process did develop in the anterior part of the pelvic ring suggests that the ring in these cases could benefit by additional strength, which is provided by fusing the posterior joints. Our results with this procedure have been most gratifying.

The operation was performed on 3 patients and in two stages, one sacroiliac joint being fused at each stage. The operation takes half or three quarters of an hour and is not shocking to the patient. The first patient who underwent this procedure (Case 2) stood it very well. A large suprapubic abscess, which was present before operation, disappeared, and the patient continued symptom free, even though the symphysis pubis was not completely healed according to x-ray films. Curetting the symphysis pubis and laying a graft of bone across would have meant operating in a tuberculous field, which might have resulted in sinus formation.

We used this procedure also on a boy of eighteen who had draining sinuses from a suppurative process in the symphysis pubis, which later proved to be non-tuberculous in origin. After he was discharged he went to work on a bread truck, making house-to-house deliveries. He was seen several years later, still active and working hard. The sinuses had remained dry, and he was symptom-free.

The third patient (Case 4) received, in addition to the fusion of the sacroiliac joints, curettage of the diseased area and the laying of a bone graft across the pubis. It is doubtful whether the graft held, as she developed a draining sinus and spicules of bone were removed. Nevertheless, she eventually became symptom free and has remained so for three years.

It would be premature to recommend this treatment for every tuberculous symphysis pubis, but our results indicate that it should be considered, and should be used in selected cases. It seems to offer better protection against the return of the disease and its symptoms than do other procedures, and allows the patient to carry on a very active life after the disease has become arrested.

#### SUMMARY

Four cases of tuberculous symphysis pubis are reported.

The commoner signs and symptoms of this disease are described.

A new method of surgical treatment, namely the fusion of both sacroiliac joints, is described, and its results and advantages discussed.

Subsequent to submitting this paper for publication, two more cases of tuberculosis of the symphysis pubis have been admitted to this institution, which suggests that the disease is not so rare as its absence in the literature would indicate.

of erythema multiforme. These results seem incredible, and will require confirmation. However, both diseases may be so troublesome that it is well worth while to know of this treatment, even if it should be effective in only a small percentage of cases.

These advances in the handling of several recalcitrant skin diseases may be viewed with enthusiasm, but sulfanilamide must be used with great caution. There is a steadily mounting literature concerning its unpleasant and dangerous side effects. Among the various complications are the following: agranulocytosis (sometimes fatal), acute hemolytic anemia, jaundice, fever, purpura, scarlatiniform and morbilliform eruptions, erythema, urticarial tendencies and exfoliative dermatitis. The development of such complications calls for immediate withdrawal of the drug.

Of special interest is the action of sulfanilamide in producing sensitization of the skin to the action of natural sunshine or ultraviolet light. During the administration of the drug and for ten days or more following its discontinuation, a dermatitis may develop in areas exposed to either form of ultraviolet light. The implications of this fact are obvious. No person under sulfanilamide therapy should be so exposed.

#### PSORIASIS

The mystery of psoriasis remains unsolved, but recent investigations have produced evidence which challenges verification and two outstanding new lines of therapy have been described.

As one reviews the old and the new literature on the treatment of psoriasis, impressive descriptions of dozens of fantastically successful "cures" may be found. There, one may find the case histories of hundreds of psoriatic patients who though suffering from severe and widespread involvement for many years, have cleared up under one or another new form of therapy. The typical patient resists all forms of treatment until finally he submits to the "Asiatic pill," whole pancreas, injection of psoriatic scales, cortical hormone, liver, gold, deep x-ray therapy to the spine, colloidal sulfur, colloidal manganese or some one of many apparently unrelated types of therapy.

It is important to recall that these brilliant results are reported by authors of unquestioned integrity and ability. Their authenticity cannot be questioned. The case histories are convincing because so many of the patients have resisted all therapeutic approaches and have remained unimproved for years, but have cleared up dramatically in response to one of many diverse treatments. Perhaps psoriasis is a disease of multiple etiology and is amenable only to multiple types of

treatment. It does seem true that one often finds the answer to stubborn cases of psoriasis only in a persistent search, by a trial-and-error method among the many available methods of treatment.

At the present time, in facing the problem of treating this disease, the practitioner should be well acquainted with the technic of administering several of the best accepted forms of treatment. He should bear in mind the efficacy of 3 to 6 per cent crude coal tar, 0.1 to 0.25 per cent anthralin to 6 per cent chrysarobin and 5 to 20 per cent moniodinated mercury ointments. These agents are among the best. Ultraviolet light is good therapy and may be given in the office, or the patient may purchase a lamp and receive more frequent administered exposures at home, after adequate instructions.

X-ray is useful to a limited extent, but should scarcely ever be employed to the exclusion of other methods. For the treatment of the patient having only a solitary patch of psoriasis, x-ray seems to be particularly effective and lasting in its action. In the average case with more widespread involvement, psoriasis clears up almost uniformly with x-ray, but recurrence is the rule, and it should therefore be used only in carefully selected cases and with great conservatism. Psoriasis is a chronic recurrent disease, and the use of x-ray always introduces the hazard that the patient may receive an excessive and unsafe total dosage. Remembering the beneficial effects of the first course of x-ray, he is apt to seek further treatment, and go to a succession of doctors until he gets it. It seems likely that colloidal manganese will stand the test of time and rate a substantial place in the general therapeutic armamentarium, at least if a true specific is found.

In the very long list of therapeutic methods, two outstanding new agents have been mentioned: sarsaparilla and vitamin D. In my experience, both of these methods are well worth trying, but sarsaparilla has seemed to give results far less uniform than those represented in published reports. Vitamin D is known to be effective in only 50 per cent of cases. In 6 successive cases I studied the effects of sarsaparilla consumed faithfully in large doses for several months. Convincing results were not obtained, but in a seventh case a therapeutic miracle was witnessed, and surprisingly good results have been seen in several patients treated by sarsaparilla combined with other remedies. The sarsaparilla treatment of psoriasis goes out of studies concerning fat metabolism of the disease. The total blood fat, cholesterol and blood phosphatids are all about 40 per cent elevated in psoriasis, according to studies by Bürger and Ullrich.

Very favorable results in the treatment of

were larger than about half the size of a pea. The left ovary was freely movable and about twice the normal size. About two thirds of it was made up of a single cyst, the capsule of which was extremely thick. There was present, projecting through the wall of the capsule on the upper surface of the ovary, a hard mass. The remaining portion of this ovary appeared normal. The right tube and ovary were removed, and the capsule over the hard structure on the surface of the left ovary was incised. The mass was removed and was found to be a tooth. Cheese like material oozed through the incision, which was clamped in order to prevent further escape. An incision was made through the normal portion of the ovary just below the level of the capsule, and the cyst was completely removed. The raw surface of the remaining portion of the ovary appeared to be normal, and the surfaces were approximated by means of a continuous figure-of-eight stitch. Reconstruction of this portion of the ovary was accomplished, leaving an organ which was about 3 cm long, 1 cm wide and 1 cm deep. Appendectomy was performed, and the abdomen was closed in layers.

The postoperative course was uneventful, and the patient was discharged on the 14th postoperative day. The pathological examination disclosed the right ovary to be replaced by a cystic cavity, filled with greasy, yellowish material and a moderate amount of hair, and the small cyst of the left ovary to be filled with greasy material and two small cysts filled with clear fluid, accompanied by a small tooth. The final pathological diagnosis of all the tissues removed read as follows: Bilateral dermoid cysts of the ovaries, healed salpingitis, healed appendicitis, no evidence of malignancy.

Follow up examinations were made on July 28, August 26 and November 25, 1938, and January 20, 1939. Rectal examination on each of these dates disclosed the uterus to be normal in size and position, and the left ovary to be

about the same in size as it was after repair at the time of the operation. In addition, great importance is attached to the fact that since the operation the menstrual periods have occurred with regularity (every 28 days), have not been painful and have lasted as long as they did prior to the operation.

#### CONCLUSIONS

As previously stated, conclusions should not be drawn from the results of one case. Yet, because this patient has had normal menstrual periods without menopausal symptoms since operation, and because this technic is rarely described in the literature, it becomes apparent that a paper of this type may have value for several reasons. It may encourage the employment of this procedure and also impel others to describe their results in the various medical journals. The hope is held out that a possible guide for surgical conduct may develop by the accumulation of such papers, so that one may give an accurate prognosis, based on results obtained in many cases of this type.

## REPORT ON MEDICAL PROGRESS

### DERMATOLOGY

PERRY C BAIRD, JR., M.D.

BOSTON

THIS brief consideration of present trends in the field of dermatology is in no sense intended to be comprehensive. Instead, several important subjects have been selected and these have been dealt with from a practical viewpoint.

#### SULFANILAMIDE

The steadily increasing use of sulfanilamide in the treatment of diseases of the skin is to be expected from the widespread use of the drug in other conditions. In England and in this country, cases of actinomycosis have been reported to recover following the use of sulfanilamide, after standard forms of treatment had failed.<sup>1</sup> It seems unlikely that all cases of actinomycosis will respond to

sulfanilamide as well. Nevertheless, in dealing with so virulent a disease, any suggestion regarding treatment is always welcome and further trial of the drug seems justifiable. Erysipelas, lymphogranuloma inguinale and chancroid seem to respond well to this useful chemical.<sup>2-4</sup> Cases of pemphigus have also been reported to respond favorably.<sup>5</sup>

In a recent address before the New England Dermatological Society, Abramowitz<sup>6</sup> reported remarkable results in the treatment of the highly fatal disseminating type of lupus erythematosus by small doses of sulfanilamide (5 to 20 gr daily by mouth). With similar doses he obtained excellent results in the management of bullous types

To the scalp, the following ointment (Foerster's scalp ointment) may be applied one or more times weekly, with shampoos one or more times weekly

R	Salicylic acid	2.00
	Sulfur (precipitated)	2.00
	Solution of coal tar (N. F.)	8.00
	Aquaphor (Duke)	
	Lanolin	aa ad 60.00

The following lotion (Markley's scalp lotion) may be applied daily

R	Salicylic acid	4.00
	Solution of coal tar (N. F.)	4.00
	Camphor water (U. S. P.)	30.00
	Alcohol (75%)	q s ad 180.00

General medical studies are in order, and search should be made for foci of infection, intestinal disorders and lowering of the basal metabolism. The presence of acne, however, is by no means a necessary indication that there is anything wrong with the general health. It is my experience that many patients with typical acne are vigorous, healthy, athletically inclined young people, who on expert medical examination prove to be quite normal in all respects so far as can be determined. Some of them seem to be not only healthy but exuberantly so. If some glandular abnormality must be presumed to be a factor, one cannot avoid the assumption that in these vigorous young people there may be some glandular overfunction rather than underfunction. It is well recognized that severe acne may be associated with adrenocortical tumors. The mechanism of acneiform eruption in this group of cases has never been explained adequately, but the cause may well be an oversecretion of the cortical hormone or a secondary hypersecretion of the male sex hormone, for prolonged administration of the cortical hormone to male rats produces hypertrophy of the sexual apparatus. Since acne occurs in 60 per cent of adolescent women and 70 per cent of adolescent men (Bloch), it may be argued that whatever the glandular factor may be, it must be a part of normal adolescence.

X-ray therapy remains one of the most effective weapons in the treatment of acne, particularly if employed in conjunction with good general dermatological care. Results from x-ray therapy are, however, far short of 100 per cent, though some claim it will cure 80 per cent of cases. It must

Endocrine preparations (female sex hormones (amniotin, and so forth) at various stages of pregnancy have been tried with disappointing results. Disappointment concerning the therapy of acne has been expressed by Wise and Sulzberger,<sup>12</sup> Templeton and Telford,<sup>13</sup> and others. For a careful review of the extensive studies, the reader is referred to the reports by these men and to the discussions of these papers. There is a percentage of the patients who do not respond to those obtained by orthodox therapy.

Despite the failure of orthodox therapy, one hopes that more light will be thrown on this subject and that a successful method will be devised. While awaiting the results of their studies of the urinary excretion of female sex hormones (Wile and Wile),<sup>14</sup> they found that in both sexes the excretion was increased and that the clinical picture was improved. If hypersecretion of androgenic glandular factor in acne, or any other form of glandular abnormality is involved, the present endocrine therapy is aimed in quite the wrong direction. It is devised exclusively on the basis of the supposed glandular underfunction and the balancing of glandular deficiency rather than the problem of dealing with glandular overfunction. This concept has led to disappointing results currently.

Recent evidence tends to show that in large doses may be of value in the pustular element of acne. The oiliness of the skin and comedones are unchanged, but the more severe secondary infection improves.

Highly successful results have been obtained<sup>17</sup> in 76 per cent of cases by viosterol in daily doses.

Daily doses of vitamin A of 20,000 and 100,000 U.S.P. units by Hinrichsen and Ivy,<sup>18</sup> results in one to five months in that the action of vitamin A on acne was to increase the thickness of the stratum corneum.

of psoriasis were obtained by a low-fat diet, but this form of treatment had to be continued over a period of many months and to most patients proved very burdensome. Therefore, search was made for some therapeutic agent which might be useful in lowering the blood fat without its being necessary to resort to a low-fat diet. An old remedy was resuscitated, namely the sarsaparilla root, which contains saponin as its chief active principle, and since saponin possesses the power of combining with cholesterol, it seemed a logical remedy.

The sarsaparilla treatment consists of the administration of ten to forty-five tablets (Sarsaparilla-Tabletten Bürger)\* daily for from three to five months or more. Slight to marked restriction of the fat content of the diet is usually recommended, but local treatment is omitted. After all evidences of psoriasis have completely cleared, a small maintenance dose of sarsaparilla is recommended in some instances, but in other cases, all treatment is stopped and recurrence does not take place.

Impressive results have been reported in patients treated by this method. Severe cases of psoriasis of from five to eighteen years' duration have recovered remarkably following this treatment, according to the work of Deneke.<sup>8</sup> Excellent results comparable to those reported by Deneke were reported in the summer of 1938 by Zaun,<sup>9</sup> who studied and treated 20 cases by the same method. He administered five to thirty tablets of sarsaparilla daily with large amounts of fluid, a low-fat diet and a simple salicylic acid ointment applied locally. Satisfactory results were obtained in all the cases except in a few in which the patients did not follow treatment regularly.

The use of vitamin D in the treatment of psoriasis seems logical because of the known response of many cases to natural sunshine and to artificial ultraviolet radiation. However, the doses of vitamin D found to be useful in psoriasis are so extremely large that the method cannot be recommended without a note of warning. Vitamin D is the only vitamin known to be capable of doing harm. In rabbits it causes calcification of the arteries, and there is evidence that similar changes may take place in the human arterial system under the same circumstances.

The effects of massive doses of crystalline vitamin D on 15 men with extensive psoriasis were described by Ceder and Zon.<sup>10</sup> In 11 cases the cutaneous lesions cleared in twelve weeks and no unfavorable reaction was noted following administration of average daily doses of 300,000 U.S.P.

units of vitamin D. In an effort to confirm these results, Brunsting<sup>11</sup> studied 19 cases of psoriasis. Except for 3 of these the condition was of long duration, resistant to treatment and subject to frequent recurrences. Brunsting employed vitamin D in the form of Ertron, and used 300,000 U.S.P. units daily. The only local application was petrolatum. Treatment was carried out during the fall and winter months, when psoriasis is less subject to spontaneous involution. Vitamin D in these doses was apparently well tolerated. In fact, in most cases during the early weeks of treatment there was an added sense of well-being. In 2 there was slight elevation of blood calcium associated with nausea and headache, but these symptoms disappeared after treatment was discontinued for a week or two. Of these 19 cases so treated, excellent results were obtained in 10. Three cleared completely, and 7 were markedly improved in from two to seven months.

In evaluating this method of treatment it must be borne in mind that definite danger is involved in the administration of vitamin D in large doses to human beings over a long period of time. Among children especially, the procedure should be used with the utmost caution.

#### ACNE VULGARIS

The emotional and social development of young people of either sex may be affected materially by the embarrassing if not disfiguring effects of conspicuous degrees of acne. Too often the parents of these youngsters are advised to do nothing and are urged to allow their children merely to outgrow the disturbance. Acne may not disappear spontaneously until the age of twenty-six years or later. Even without resorting to expensive dermatological care with x-ray and frequent office visits, much can be accomplished in moderating the effects of acne by means of simple home procedures including facial and scalp hygiene, dietary measures, local applications to the scalp and face, regulation of the bowels, proper use of soap and water, and so forth.

A suitable facial lotion which may be applied once or twice daily is the following:

R. Phenol	3 00
Camphor	2 40
Sulfur (precipitated)	2 00
Calamine	4 00 to 10 00
Zinc oxide	4 00 to 10 00
Alcohol (95%)	30 00
Glycerin	8 00
Water	q. s. ad 240 00

If this should prove to be too drying, it may be diluted with equal parts of water.

\*Manufactured as Sarsapar by Johannes Bürger'sat Fabrik, Wernigerode.

determined more by the state of the skin than by the cause of the eruption. In infantile eczema the most promising therapeutic approach is that which is directed against the presenting manifestation, such as the removal of crusts and scales, the combating of infections, the soothing of irritations, the alleviation of itching and the prevention of scratching.

The most practical point of view for both physician and mother is that which regards infantile eczema as a result of maladjustment of the skin to the radical changes of environment which occur when the baby is born. The skin is the most delicate and the most exposed organ, and it is that organ which has to the greatest degree the function of protecting the individual from the outside world and of adapting him to his environment. All the new substances of the outside world including dust, feathers, wool, silk, animal emanations, cleansing agents, soaps, and so forth, begin their onslaught. The various physical forces such as heat, cold, light, moisture, friction and pressure all require cutaneous adjustment. Hordes of living micro-organisms including fungi, bacilli, cocci and viruses begin to settle on the surface of the skin and take up their activities there, and these must be controlled and resisted. In addition to all these external attacks, the skin must learn to cope with the products of digestion which are brought to it in the blood stream, and to adjust itself to substances absorbed by inhalation. Furthermore, the skin must adapt itself to the products emanating from new foci of internal and external infection.

In treatment, therefore, the eczematous baby should be protected so far as possible from the violence of these varied onslaughts. The temperature of the room and of the entire environment should be kept even (about 68°F). The clothing should be light, soft and cool, and next to the skin smooth cotton or linen should always be used in preference to woolen or other rough material. The baby's skin should be kept clean and soft, and this must be accomplished without the use of soap. If there is one point on which all authors agree, it is this. Except on the scalp, soap is "poison" for most infantile eczemas. Care should be taken to see that no soap remains in the clothing or bed linen, thorough and repeated rinsing of all garments and linen is essential. Instead of soap's being used, the child should be bathed with tepid water to which starch, oatmeal or tar has been added, it is surprising how well one can clean a child by such means.

Eczematous skins are almost always sensitive to friction and to alkalis, and the diapers must

therefore always be soft, clean, loose and free from every trace of soap. Rubber pants and the like should be dispensed with. The effects of ammoniacal stool and urine must be prevented, and this is most readily accomplished by rinsing the diapers, after washing, with a mildly acid and antiseptic solution. In most instances it is sufficient to soak the diapers in a saturated solution of boric acid.

If after a reasonable trial any case of infantile eczema proves refractory to topical measures, it is advisable to undertake the elimination, one by one, of such potential common dietary causes as cow's milk, wheat, eggs, citrus fruits, spinach, peas, tomatoes, fish and fish products, named in their approximate order of importance. In regard to diet, the approach to this subject by means of a carefully taken history, the close observation of the effects of elimination and re-exposure to certain foods and the constant awareness that a few foods are notorious offenders will as a rule prove more successful than reliance on results of hundreds of cutaneous tests.

Environmental allergens such as house dust and the substances coming from pillows, mattresses, bedding, rugs, draperies and dyed and colored objects may be of great significance in certain cases of infantile eczema. It is therefore expedient to remove all sources of such dust. No feathers, Kapok mattresses, overstuffed furniture, rugs or draperies should be present. The room should be as bare as a barracks, with washable walls and floors if possible. An iron cot with a sterilized horsehair mattress and plain, painted wooden chairs should constitute the bedroom furniture. If Kapok or feathers cannot be removed, the mattress, pillows or other articles containing these allergens should be covered with a so-called allergen-proof cover.

In the matter of reassuring parents, Sulzberger mentions several points of considerable helpfulness.

- 1 The baby will almost certainly get over the cutaneous disorder. In most cases, there is spontaneous cure at about the age of two years or before.
- 2 No marks and no scars will be left by the eruption. The child's skin has every prospect of eventually being as perfect as that of any other child.
- 3 The cutaneous condition is not contagious.
- 4 The baby is a healthy one. The general health and the nutrition will not suffer because of the eczema.
- 5 There is practically no danger whatsoever of blood poisoning in spite of all the scratching.
- 6 The baby is not really suffering to the extent to which it appears to be. When it gets over this trouble no general impairment of health will remain, and no memory of the episode will persist.

The commonest forms of pruritus ani are due to fungous infections, seborrheic dermatitis and psoriasis. For practical purposes, all three of these types may be treated by identical methods. The perianal skin changes in this group are too familiar to require description, and consist of varying mixtures of erythema, scaling, maceration, excoriation and fissuring.

The practitioner will meet with far greater success in treating pruritus ani if he remembers that fecal staining is always an exciting factor of importance. Small amounts of fecal material left in the skin folds after defecation and the particles deposited after passing gas are capable alone of causing marked itching. Irritation from fecal material probably not only serves to stir up and aggravate perianal fungous infections but may prepare the soil for the original inoculation. Therefore in treatment rigid cleanliness is essential. Careful instructions should be given to cleanse the area with olive oil and Kleenex following each bowel movement, and also following episodes of passage of gas per rectum during the day. This latter point cannot be stressed too strongly.

Lilienthal<sup>19</sup> has outlined a very successful form of treatment which seems to be based almost entirely upon the simple principle of protecting the anal region against contamination with fecal matter. The affected parts are thoroughly cleansed at the start with any of the noninflammable grease solvents and the area is allowed to dry. The fissures and folds of the area are thoroughly filled with some bland substance such as ordinary zinc oxide ointment. The patient is then instructed to apply a thick coating of zinc ointment before each evacuation. In this way, the fecal material is prevented from coming in contact with the affected area of skin, and after the movement the stains may be easily removed with soft paper. After the inflammatory changes have subsided, a lighter type of ointment may be used as a prophylactic to replace the heavy zinc ointment mixture. A high percentage of success has been reported from the use of this simple and very plausible type of treatment.

The commonest error in treating pruritus ani lies in the use of excessively strong antiseptic applications. Whitfield's ointment and its commercial imitations (Kerolysin) contain 6 per cent salicylic acid and 12 per cent benzoic acid, and are much too corrosive for the sensitive anal region, in the average case. More suitable local remedies include permanganate (1:10,000 dilution) wet dressings, ointments containing 1 to 3 per cent salicylic acid, 1 to 3 per cent sulfur, 3 per cent pine tar ointment (USP), 5 to 10 per cent ammoniated mercury, 6 per cent crude coal tar or

5 to 10 per cent Supertah, and many others. The use of crude coal tar ointment is a "messy" type of treatment but is one of the best.

To be highly recommended in the treatment of pruritus ani is the following formula (Foerster's groin ointment)

R	Salicylic acid	2.00
	Sulfur ointment (USP)	2.00
	Pine tar ointment (USP)	2.00
	Aquaphor (Duke)	q s ad. 60.00

This may be applied directly to the affected area, morning and night.

It is well to keep in mind that all fungicidal remedies for pruritus ani are potential allergens, and that their use is complicated frequently by varying degrees of chemical dermatitis, which may serve to aggravate the condition considerably. The patient should be warned of this possibility so that his confidence will be preserved, and alternative forms of treatment substituted if necessary.

X-ray is sometimes an indispensable aid in the therapy of pruritus ani, and ultraviolet light proves to be of value in occasional cases. Neither x-ray nor lamp should, however, be used to the exclusion of anal hygiene and properly selected local applications.

#### INFANTILE ECZEMA

In the management of infantile eczema, Sulzberger<sup>20</sup> has presented a highly practicable and simplified conception along with many clear-cut suggestions regarding treatment. Sulzberger considers that the expert should be able to differentiate eight different forms of eczematoid dermatoses, but he expressed doubt whether the general practitioner will, in the present rudimentary state of knowledge in this field, derive much value in attempting to distinguish between the various forms of eczematoid dermatitis in children below the age of two years. There are several good reasons for this, including the fact that the infantile eczematoid eruptions do not as a rule present the typical distributions which constitute such important aids in the differential diagnosis of the adult form. In addition, the tendencies toward vesiculation and weeping, which are almost pathognomonic of adult contact type of dermatitis, and which are completely absent in the uncomplicated atopic type and seborrheic dermatitis in adults, are likely to be present in all forms of infantile eczema.

Sulzberger considers that, from the purely practical viewpoint, the physician will be more successful if he discards theory and, for the present at least, regards infantile eczema as a cutaneous eruption to be managed as a single disease, and he advises that the dermatological treatment be

determined more by the state of the skin than by the cause of the eruption. In infantile eczema the most promising therapeutic approach is that which is directed against the presenting manifestation, such as the removal of crusts and scales, the combating of infections, the soothing of irritations, the alleviation of itching and the prevention of scratching.

The most practical point of view for both physician and mother is that which regards infantile eczema as a result of maladjustment of the skin to the radical changes of environment which occur when the baby is born. The skin is the most delicate and the most exposed organ, and it is that organ which has to the greatest degree the function of protecting the individual from the outside world and of adapting him to his environment. All the new substances of the outside world including dust, feathers, wool, silk, animal emanations, cleansing agents, soaps, and so forth, begin their onslaught. The various physical forces such as heat, cold, light, moisture, friction and pressure all require cutaneous adjustment. Hordes of living micro-organisms including fungi, bacilli, cocci and viruses begin to settle on the surface of the skin and take up their activities there, and these must be controlled and resisted. In addition to all these external attacks, the skin must learn to cope with the products of digestion which are brought to it in the blood stream, and to adjust itself to substances absorbed by inhalation. Furthermore, the skin must adapt itself to the products emanating from new foci of internal and external infection.

In treatment, therefore, the eczematous baby should be protected so far as possible from the violence of these varied onslaughts. The temperature of the room and of the entire environment should be kept even (about 68°F). The clothing should be light, soft and cool, and next to the skin smooth cotton or linen should always be used in preference to woolen or other rough material. The baby's skin should be kept clean and soft, and this must be accomplished without the use of soap. If there is one point on which all authors agree, it is this. Except on the scalp, soap is "poison" for most infantile eczemas. Care should be taken to see that no soap remains in the clothing or bed linen, thorough and repeated rinsing of all garments and linen is essential. In stead of soap's being used, the child should be bathed with tepid water to which starch, oatmeal or tar has been added, it is surprising how well one can clean a child by such means.

Eczematous skins are almost always sensitive to friction and to alkalis, and the diapers must

therefore always be soft, clean, loose and free from every trace of soap. Rubber pants and the like should be dispensed with. The effects of ammoniacal stool and urine must be prevented, and this is most readily accomplished by rinsing the diapers, after washing, with a mildly acid and antiseptic solution. In most instances it is sufficient to soak the diapers in a saturated solution of boric acid.

If after a reasonable trial any case of infantile eczema proves refractory to topical measures, it is advisable to undertake the elimination, one by one, of such potential common dietary causes as cow's milk, wheat, eggs, citrus fruits, spinach, peas, tomatoes, fish and fish products, named in their approximate order of importance. In regard to diet, the approach to this subject by means of a carefully taken history, the close observation of the effects of elimination and re-exposure to certain foods and the constant awareness that a few foods are notorious offenders will as a rule prove more successful than reliance on results of hundreds of cutaneous tests.

Environmental allergens such as house dust and the substances coming from pillows, mattresses, bedding, rugs, draperies and dyed and colored objects may be of great significance in certain cases of infantile eczema. It is therefore expedient to remove all sources of such dust. No feathers, Kapok mattresses, overstuffed furniture, rugs or draperies should be present. The room should be as bare as a barracks, with washable walls and floors if possible. An iron cot with a sterilized horsehair mattress and plain, painted wooden chairs should constitute the bedroom furniture. If Kapok or feathers cannot be removed, the mattress, pillows or other articles containing these allergens should be covered with a so-called allergen-proof cover.

In the matter of reassuring parents, Sulzberger mentions several points of considerable helpfulness.

- 1 The baby will almost certainly get over the cutaneous disorder. In most cases, there is spontaneous cure at about the age of two years or before.
- 2 No marks and no scars will be left by the eruption. The child's skin has every prospect of eventually being as perfect as that of any other child.
- 3 The cutaneous condition is not contagious.
- 4 The baby is a healthy one. The general health and the nutrition will not suffer because of the eczema.
- 5 There is practically no danger whatsoever of "blood poisoning" in spite of all the scratching.
- 6 The baby is not really suffering to the extent to which it appears to be. When it gets over this trouble, no general impairment of health will remain, and no memory of the episode will persist.

Statements of this type will often pave the way to cure by reassuring the members of the distressed family so that they become of valuable assistance in the further management of the case

### VITAMINS AND THE SKIN

The skin, which carries a storage of vitamins A, C, D and possibly B<sub>2</sub>, may reflect the earliest clinical signs of vitamin deficiency, a fact worth bearing in mind in this age of vitamin enthusiasm. For example, the dryness, scaliness and other cutaneous changes characteristic of vitamin A deficiency may appear before the onset of night blindness or xerophthalmia. So much attention has been focussed recently upon the vitamins, in relation to health and diseases, that it is worth while to know what the skin teaches us about this interesting subject. Recent reports concerning vitamins and the skin have come from Youmans and Corlette<sup>21</sup> concerning vitamin A and from Goodman,<sup>22</sup> who has made an extensive review of the literature.

#### *Vitamin A Deficiency*

In vitamin A deficiency the skin undergoes quite distinctive alterations. Some cases show a dry, horny condition with peculiar conical papules arising at the sites of the hair follicles and involving particularly the thighs, arms and buttocks. These changes completely disappear following the administration of cod-liver oil or haliver oil. In other cases, an acneform papular eruption involving chest, back, arms and shoulders may dominate the picture. Comedones of the face may appear, but these are more keratotic than in true acne. Pustulation is rare except as a late manifestation. The fingernails and toenails may undergo changes including lack of luster and brittleness. The acneform disturbances and the nail changes may be corrected by vitamin A therapy in the form of either haliver oil or cod-liver oil.

#### *Vitamin B<sub>2</sub>(G) Deficiency*

The dermatitis of pellagra is brought out by the action of sunlight on the exposed areas of the skin, including face, neck, wrists and backs of hands, in subjects who have subsisted on a prolonged, grossly deficient diet. The areas affected become brightly erythematous and present sharp lines of demarcation. Thickening, desquamation and pigmentation develop later. The symptoms of pellagra are relieved by the administration of brewer's yeast, liver extract or nicotinic acid combined with a liberal and well-balanced diet.

#### *Vitamin C Deficiency*

In scurvy, the capillary walls become fragile and hemorrhages occur with ease. Swollen gums, ecchymoses and purpuric and hemorrhagic tendencies become evident. In both vitamin A and vitamin C deficiency follicular hyperkeratosis occurs, and the early follicular lesions in these two conditions are indistinguishable. In more advanced stages, however, the hyperkeratosis of the hair follicles in scurvy may be distinguished by perifollicular hemorrhages. Follicular hyperkeratosis may be the first recognizable sign of the scorbutic tendency, and may permit diagnosis before the onset of other scorbutic symptoms.

All symptoms of scurvy, including the pigmentation seen in occasional cases, may be relieved quite promptly by the administration of orange juice, lemon juice, tomato juice and other rich sources of vitamin C. Cevitamic acid, the crystalline form of this vitamin, may also be used.

Of great interest is the convincing literature which has accumulated in the last few years concerning a relation between vitamin C and hypersensitiveness to arsphenamine.<sup>23</sup> In the treatment of exfoliative dermatitis due to arsenical therapy, vitamin C has been employed with success far surpassing the older methods used in this troublesome ailment. The evidence is that vitamin C should be employed routinely in large dosage as an adjunct in arsphenamine therapy.

#### *Other Vitamins*

The relations between vitamins B<sub>1</sub>, E and F and the skin are at present so ill defined clinically as to merit no special mention in this summary.

In the treatment of acne, psoriasis and pemphigus, vitamin D seems to be of value if employed in large dosage. There is little clear-cut evidence, however, that deficiency of vitamin D is of importance in the etiology of these diseases.

Pustulation is rare except as a late manifestation. The fingernails and toenails may undergo changes including lack of luster and brittleness. The acneform disturbances and the nail changes may be corrected by vitamin A therapy in the form of either haliver oil or cod-liver oil.

#### *Vitamin B<sub>2</sub>(G) Deficiency*

The dermatitis of pellagra is brought out by the action of sunlight on the exposed areas of the skin, including face, neck, wrists and backs of hands, in subjects who have subsisted on a prolonged, grossly deficient diet. The areas affected become brightly erythematous and present sharp lines of demarcation. Thickening, desquamation and pigmentation develop later. The symptoms of pellagra are relieved by the administration of brewer's yeast, liver extract or nicotinic acid combined with a liberal and well-balanced diet.

#### *Vitamin C Deficiency*

In scurvy, the capillary walls become fragile and hemorrhages occur with ease. Swollen gums, ecchymoses and purpuric and hemorrhagic tendencies become evident. In both vitamin A and vitamin C deficiency follicular hyperkeratosis occurs, and the early follicular lesions in these two conditions are indistinguishable. In more advanced stages, however, the hyperkeratosis of the hair follicles in scurvy may be distinguished by perifollicular hemorrhages. Follicular hyperkeratosis may be the first recognizable sign of the scorbutic tendency, and may permit diagnosis before the onset of other scorbutic symptoms.

All symptoms of scurvy, including the pigmentation seen in occasional cases, may be relieved quite promptly by the administration of orange juice, lemon juice, tomato juice and other rich sources of vitamin C. Cevitamic acid, the crystalline form of this vitamin, may also be used.

Of great interest is the convincing literature which has accumulated in the last few years concerning a relation between vitamin C and hypersensitiveness to arsenamine.<sup>23</sup> In the treatment of exfoliative dermatitis due to arsenical therapy, vitamin C has been employed with success far surpassing the older methods used in this troublesome ailment. The evidence is that vitamin C should be employed routinely in large dosage as an adjunct in arsenamine therapy.

#### *Other Vitamins*

The relations between vitamins B<sub>1</sub>, E and F and the skin are at present so ill defined clinically as to merit no special mention in this summary.

In the treatment of acne, psoriasis and pemphigus, vitamin D seems to be of value if employed in large dosage. There is little clear-cut evidence, however, that deficiency of vitamin D is of importance in the etiology of these diseases.

## CASE 25191

### PRESENTATION OF CASE

A sixty-nine-year-old married Italian woman was admitted complaining of swelling of the legs and shortness of breath.

She was born in Italy and had lived there for fifty years in good health. Fifteen years prior to admission, approximately at the time of coming to Boston, she developed a chronic cough which was productive of a small amount of white phlegm. The cough was noticed especially in the morning. It was never blood streaked. She saw numerous physicians without relief. There was no weight loss, weakness, anorexia or fever. At times the coughing attacks lasted until her skin became blue. One and a half years before entry she noticed shortness of breath following activity, and swelling of her legs after standing, for which she was treated with "red capsules." The attacks which resulted in her becoming blue returned at that time. She resumed normal activity after three weeks. During the previous year she had noticed shortness of breath on climbing stairs, and at times her legs became markedly swollen at night, the swelling disappearing in the morning. Six weeks before admission she had had an attack of shortness of breath in the morning to the extent that she could not speak. During the previous four weeks, without evident cold, sore throat or infection, she became progressively bluer. Her legs became swollen and she went to bed, but in bed her abdomen and buttocks became swollen. Her cough persisted. She gained about 30 pounds in weight. During the previous three weeks she had been given two pills of digitalis daily for one week, followed by one pill daily for two weeks. "Brown pills" and Salyrgan injections were also given, which increased her urinary output.

Physical examination showed a large, blackly cyanotic, orthopneic woman in acute distress, with short rapid shallow respirations. The cyanosis involved the face, neck and hands. The superficial veins were markedly distended, especially those of the neck which showed also a deep sustained venous pulse. The heart was enlarged to the left anterior axillary line and 4.5 cm. to the right of the midline. There was a prominent pulsation in the pulmonic area, with systolic and diastolic

shock. P<sub>2</sub> was much louder than A<sub>2</sub>. There was a faint systolic apical blow, and a faint third sound. The rate was regular at 80. The blood pressure was 136 systolic, 70 diastolic. The lungs were resonant but full of moist rales and rhonchi, especially in the lower lobes. The liver was enlarged to about 10 cm. below the right costal margin. The chest was not barrel-shaped, but was fairly large, consistent with her large build. There was a definite fluid wave in the abdomen, and edema up to the waist. Rectal and pelvic examinations were negative.

The temperature was 99.5°F, rectally, the pulse 70, and the respirations 30.

Examination of the urine was negative except for 8 to 10 white cells per high-power field. The blood showed a red-cell count of 6,610,000 with 110 per cent hemoglobin, and a white-cell count of 7300 with 76 per cent polymorphonuclears. Blood Hinton and Wassermann tests were not done. An electrocardiogram showed low T waves in all four leads. QRS<sub>1</sub> and QRS<sub>2</sub> were slightly slurred, ST<sub>3</sub> sagging. There was right axis deviation.

After arrival on the ward from the Emergency Ward it was thought that she tried to indicate pain over her heart. Following this her pulse dropped to 56. On the second hospital day her circulation time (arm to medulla, lobelin method) was 30 seconds (normal, 15 seconds). The venous pressure was 270 mm. of water. Digitalis and Salyrgan had no obvious effects. An oxygen tent partly relieved the cyanosis, but she continued rapidly downhill, became unconscious and died three days after admission.

### DIFFERENTIAL DIAGNOSIS

DR. DONALD KING. The clinical picture in this case seems clear. In the first place, there is right-sided cardiac failure of extreme degree, with all the signs that go with that condition. In the second place, the right-sided failure is probably due to gross changes in the pulmonary vascular bed. I cannot think of any other lesion which would give the pulsation in the pulmonary area, with the double shock and the very marked or black cyanosis. In the third place, I know of only three conditions which would so obstruct the pulmonary vessels. Of course, we have to think of Ayerza's disease, but this patient was sixty-nine years old and I do not believe that patients with obliterating arteritis, which we mean when we speak of Ayerza's disease, would live to be that old. I do not believe that in this case a syphilitic infection or any other specific etiologic factor is producing obliteration of the arteries. That leaves only extensive thrombosis or multiple emboli, and my

diagnosis will be multiple pulmonary emboli, with probable thrombi and infarcts

To go a little farther, what possible conditions would be associated with such vascular changes? We should like to find something to explain them. We have no evidence of phlebitis in the peripheral vessels. There is no evidence of anything wrong in the heart, except the cor pulmonale with right-sided failure. There is no indication of coronary thrombosis, valvular disease, hypertensive heart disease, constrictive pericarditis or a congenital heart lesion. There is no fibrillation, and no proof that there are mural thrombi. So far as the lungs go, we have the story of a morning cough for fifteen years. There is nothing in the history or physical examination to warrant the diagnosis of emphysema. A true cor pulmonale is usually associated with emphysema, particularly if chronic bronchial infection is present. We have then no evidence of cardiac or pulmonary lesions, and all we know is that there are marked changes in the pulmonary vessels. You may remember that a year ago Dr. Means discussed a similar case.\* To complete the picture I shall assume that the autopsy showed phlebitis, perhaps in the popliteal or pelvic vessels. I shall assume that the heart was negative and that the lungs showed multiple emboli with thrombi and multiple small pulmonary infarcts. I do not know why the record should stress the fact that a Wassermann test was not done, in any case, I shall throw out the possible diagnosis of syphilis.

DR. TRACY B. MALLORY: Does anyone want to disagree or to hazard another diagnosis?

DR. KING: I might say that in this case we have to make the diagnosis of pulmonary emboli and infarcts without a source that can be demonstrated, —without pain, without hemoptysis and without fever,—but we have had such cases. I do not see how we can make any other diagnosis.

I did not see the x-ray film.

DR. MALLORY: You are welcome to it.

DR. KING: I am at a loss to explain the fifteen years' cough, and this x-ray film does not help. I believe that there was some clinical emphysema. Perhaps early stages of cardiac failure would explain the cough. In Dr. Means's case, which I looked up today, the patient had had cough for many years and repeated attacks of bronchitis, so-called, yet the postmortem showed no change in the lungs.

DR. J. H. MEANS: There is another case that Dr. Mallory and I reported years ago. At postmortem there was a thrombosis in the pulmonary artery which completely occluded one main branch. The

circulation of the lung had been taken care of by a bronchial artery as big as my little finger. There was marked cyanosis.

DR. KING: As black as in the present case?

DR. MEANS: Not quite.

DR. KING: The cyanosis seems to have been the most marked that we have ever seen in cases of pulmonary emboli.

DR. MEANS: I should like to raise the question, and have Dr. Mallory comment, as to whether there is any extravascular lesion which could impinge on the pulmonary artery in any fashion so as to give cyanosis such as this.

DR. MALLORY: I do not remember ever having seen one.

DR. KING: I tried to bring carcinoma into this picture but could not.

DR. RICHARD SCHATZKI: You may be glad you did not have the advantage of the x-ray interpretation.

DR. KING: I did not insist on it.

DR. SCHATZKI: We do not have any antemortem films. These films were taken after the patient died. The heart appears to be enlarged, but the appearance of the heart in postmortem films is absolutely unreliable, though I think that the heart was enlarged. There are definite changes in the right lower lung field, it is dense. In the lateral view there is additional evidence of a lesion in the right lower lobe and possibly the right middle lobe. This may be collapse.

DR. KING: Could it be infarct?

DR. SCHATZKI: Yes, that is what I was going to say,—a large infarct with collapse. It could be pneumonia with collapse. Whatever it is, I think it is something with marked decrease of aeration of this lobe. I do not try to interpret the vascular changes on postmortem films. The appearance of the pulmonary vessel on this film is consistent with pulmonary stasis. That is all one can say. I cannot see any calcified pulmonary vessels.

DR. KING: What about the pulmonary conus?

DR. SCHATZKI: I refuse to make any statement from the postmortem film. There is marked arteriosclerosis of the aorta if that is of any help to you.

DR. KING: You would accept pulmonary infarct?

DR. SCHATZKI: As a possibility?

DR. KING: Yes.

DR. SCHATZKI: This type of pulmonary infarct would not explain the clinical picture, would it? If this is pulmonary infarct it has come within the last few weeks.

DR. CHESTER M. JONES: Would it explain the fifteen years of cough?

DR KING Has she any evidence of emphysema?

DR SCHATZKI No gross emphysema. The films must be taken at the end of inspiration in order to see that.

DR KING She has no blebs that you can see?

DR SCHATZKI Definitely not, I should say.

DR MEANS What do postmortem x-rays show in emphysema? Does the emphysema disappear?

DR SCHATZKI I have not seen enough to say.

DR BENJAMIN CASTLEMAN The emphysema remains.

DR SCHATZKI So emphysema is out, I should say.

#### CLINICAL DIAGNOSES

Pulmonary endarteritis

Pulmonary fibrosis

#### DR KING'S DIAGNOSES

Multiple pulmonary emboli with associated thromboses and pulmonary infarcts

Probable phlebitis in popliteal or pelvic veins

#### ANATOMICAL DIAGNOSES

(Ayerza's disease)

Idiopathic cor pulmonale

Cardiac cirrhosis of liver

#### PATHOLOGICAL DISCUSSION

DR MALLORY The postmortem examination is not going to explain this case. We found, of course, a cor pulmonale. The left side of the heart was normal in size, but the heart as a whole was greatly hypertrophied, weighing 500 gm, that hypertrophy was almost exclusively due to dilatation and hypertrophy of the right ventricle. The latter was about four times as large as normal in volume, and in spite of the extreme dilatation its wall was 5 to 6 mm in thickness. If a ventricle of that size were contracted, the muscle would certainly measure at least 15 mm, quite as thick as that of the left ventricle. The lungs were normal in size. There was no trace of blebs or emphysema that could be made out in gross. The pulmonary arteries were empty. There were no thrombi or emboli, no areas of infarction. The larger pulmonary arteries appeared definitely dilated and showed numerous bright-yellow atheromatous plaques. As one progressed downward, the atheromatous plaques disappeared, but the dilatation continued as far as we could see the vessels grossly. On microscopic examination the pulmonary arterioles were absolutely normal in size and thickness. The atheromas did not extend down beyond the major branches. There were small areas in the upper lobes where there was

a slight amount of emphysema microscopically but not more than most people would consider normal for an individual approaching seventy years of age. Anyone at that age, of course, shows larger alveoli than does an individual of twenty or thirty. So I do not see how we can make a diagnosis of emphysema. The bronchi were not dilated, there was no bronchiectasis, just a minimal chronic inflammatory infiltration. There was a terminal pneumonia.

A PHYSICIAN No phlebitis elsewhere?

DR MALLORY No.

DR MEANS Do you think the diameter of the pulmonary circuit was all right?

DR MALLORY It was larger than normal.

DR ALLEN G BRAILEY What was the nature of the lesion Dr Schatzki pointed out?

DR MALLORY A terminal pneumonia in the right lower lobe.

A PHYSICIAN Was there any epithelium in the alveoli of the lungs?

DR MALLORY In a normal lung one never sees epithelium in the alveoli, and we did not see any here. We cut many sections. I am sure I looked at slides from fifteen blocks. We also examined a large amount of alveolar tissue which was cut with very thick sections that allow one to look down on the surface of the alveoli and so enable one to estimate quite accurately the vascularity of the alveolar walls. These were as vascular as I have ever seen. Certainly no diminution in the capillary bed could be made out.

A PHYSICIAN Was there any abnormal thickness of the interstitial supporting tissue?

DR MALLORY There was the average amount of interstitial alveolar tissue, nothing more.

DR A THORNTON SCOTT Is it possible it could be explained by pulmonary hypertension?

DR MALLORY It seems to be the only possible solution, but I do not know any way of proving that anatomically. I have seen an identical picture in a case that we reported as Ayerza's disease in a twelve-year-old girl. She also had black cyanosis, with a marked cor pulmonale, perfectly normal lungs, atheromas in the major arteries, but no obstructive vascular lesions whatever. This syndrome occurs without any question.

DR KING At this age?

DR MALLORY No. I should think that that is quite unusual.

DR MEANS Could the atheromatous process interfere with the elasticity of the artery sufficiently to cause an embarrassment, hemodynamically speaking, to the flow of blood through the pulmonary circuit?

DR MALLORY There is little direct relation be-

tween atheroma and elasticity of arteries. With progressive age the elasticity of the arteries diminishes regardless of atheromatous changes, and one can have severe atheromatosis in younger individuals with well-maintained elasticity. We did not actually test the elasticity of the pulmonary vessels. So far as the microscope can help, there was a normal amount of elastic tissue in the pulmonary arteries. The changes are merely superficial ones in the intima and do not involve the media at all.

DR HOWARD B. SPRAGUE: Was there any suggestion of trouble in the pulmonary veins?

DR. MALLORY: No, I looked carefully for that because by exclusion it seemed that if there were an anatomical cause it had to be found there.

DR. SIEGFRIED THANNHAUSER: There was no thickening of the heart valves?

DR. MALLORY: None whatever. The tricuspid ring was quite dilated; it is true, and I cannot say that there was not some degree of relative insufficiency and regurgitation there.

I neglected to mention that the liver showed an extreme grade of chronic passive congestion, including a definite central sclerosis, this justified a diagnosis of cardiac cirrhosis.

DR. ALBERTO C. TAQUINI: It is natural that interest in Ayerza's disease has remained very lively in South America and particularly in Buenos Aires. Bullrich and Behr<sup>1</sup> in 1925 suggested that the vascular changes seen in Ayerza's disease were probably secondary to pulmonary hypertension. In a series of experimental studies between 1930 and 1932, Ayerza, Solari and Berconsky,<sup>2</sup> Arrillaga, Berconsky and Taquini,<sup>3</sup> and Houssay and Berconsky<sup>4</sup> showed that in Ayerza's disease the oxygen tension in the alveolar air is definitely lower than normal. Their findings closely parallel those of Dautreband, Davies and Meakins<sup>5</sup> in a study of emphysema. They were able to show that cyanosis develops only when the alveolar oxygen tension drops below 80 mm of mercury. Since the oxygen content of the blood is the same as that of the alveolar air, they believe very strongly that the primary disease is due to a hypoventilation of the alveolar air, that is, to some primary malfunction of the lung parenchyma, not to disease of the circulatory system. They divide the disease into three stages: (1) bronchial—chronic bronchitis of some type which these patients almost invariably have, (2) pulmonary—extension of the disease around the bronchi and spread to the lungs producing fibrosis and emphysema, and (3) circulatory—secondary changes in the arterioles which may intensify the circulatory obstruction developing in the second stage and eventually lead to right heart failure.

DR. MALLORY: I am sure we are grateful to Dr. Taquini for this information from Ayerza's own clinic. I can only say that in this case I found very little anatomic evidence of chronic bronchitis and certainly no bronchial stenosis. I have no anatomic evidence, therefore, to explain a primary hypoventilation of the alveoli. Conceivably this could develop from faulty breathing habits and it has indeed been claimed that functional polycythemia may appear under such conditions and disappear later when the patient has been re-educated to proper breathing habits. We have, however, no positive evidence to point to any such mechanism here.

## CASE 25192

### PRESENTATION OF CASE

*First Admission* A fifty-four-year-old married Italian entered complaining of right flank pain and hematuria.

Six weeks before admission the patient had passed some bright-red urine. He had had no pain, but two hours later passed more red urine, immediately following which he was seized with a sudden, severe pain in the right testicle which radiated up through the right groin into the lumbar region where it persisted, causing the patient to double up and roll around. He was relieved by pills prescribed by his physician. Anorexia and nausea were noted, and he vomited once. Following the attack he had urinary frequency and burning. The hematuria persisted for about twenty-four hours, but a residual soreness remained in the right lumbar area for about ten days. One week before entry he passed bloody urine twice, unaccompanied by pain. Four days later he passed some thick, red urine, immediately after which there was a sudden severe pain in the right lumbar region which persisted throughout the night. The hematuria continued until entry. Frequency, dysuria and straining were present and he passed only small amounts of bloody urine, sometimes only a few drops. He had nausea but no vomiting.

Thirty years before admission he had had gonorrhea. Ten years later he was treated for syphilis.

DR KING Has she any evidence of emphysema?

DR SCHATZKI No gross emphysema. The films must be taken at the end of inspiration in order to see that.

DR KING She has no blebs that you can see?

DR SCHATZKI Definitely not, I should say.

DR MEANS What do postmortem x-rays show in emphysema? Does the emphysema disappear?

DR SCHATZKI I have not seen enough to say.

DR BENJAMIN CASTLEMAN The emphysema remains.

DR SCHATZKI So emphysema is out, I should say.

#### CLINICAL DIAGNOSES

#### PATHOLOGICAL DISCUSSION

DR MALLORY The postmortem examination is not going to explain this case. We found, of course, a cor pulmonale. The left side of the heart was normal in size, but the heart as a whole was greatly hypertrophied, weighing 500 gm, that hypertrophy was almost exclusively due to dilatation and hypertrophy of the right ventricle. The latter was about four times as large as normal in volume, and in spite of the extreme dilatation its wall was 5 to 6 mm in thickness. If a ventricle of that size were contracted, the muscle would certainly measure at least 15 mm, quite as thick as that of the left ventricle. The lungs were normal in size. There was no trace of blebs or emphysema that could be made out in gross. The pulmonary arteries were empty. There were no thrombi or emboli, no areas of infarction. The larger pulmonary arteries appeared definitely dilated and showed numerous bright-yellow atheromatous plaques. As one progressed downward, the atheromatous plaques disappeared, but the dilatation continued as far as we could see the vessels grossly. On microscopic examination the pulmonary arterioles were absolutely normal in size and thickness. The atheromas did not extend down beyond the major branches. There were small areas in the upper lobes where there was

a slight amount of emphysema microscopically but not more than most people would consider normal for an individual approaching seventy years of age. Anyone at that age, of course, shows larger alveoli than does an individual of twenty or thirty. So I do not see how we can make a diagnosis of emphysema. The bronchi were not dilated, there was no bronchiectasis, just a minimal chronic inflammatory infiltration. There was a terminal pneumonia.

A PHYSICIAN No phlebitis elsewhere?

DR MALLORY No.

DR MEANS Do you think the diameter of the pulmonary circuit was all right?

DR MALLORY It was larger than normal.

DR ALLEN G. BRAILEY What was the nature of the lesion Dr Schatzki pointed out?

DR MALLORY A terminal pneumonia in the right lower lobe.

A PHYSICIAN Was there any epithelium in the alveoli of the lungs?

DR MALLORY In a normal lung one never sees epithelium in the alveoli, and we did not see any here. We cut many sections. I am sure I looked at slides from fifteen blocks. We also examined a large amount of alveolar tissue which was cut with very thick sections that allow one to look down on the surface of the alveoli and so enable one to estimate quite accurately the vascularity of the alveolar walls. These were as vascular as I have ever seen. Certainly no diminution in the capillary bed could be made out.

A PHYSICIAN Was there any abnormal thickness of the interstitial supporting tissue?

DR MALLORY There was the average amount of interstitial alveolar tissue, nothing more.

DR A. THORNTON SCOTT Is it possible it could be explained by pulmonary hypertension?

DR MALLORY It seems to be the only possible solution, but I do not know any way of proving that anatomically. I have seen an identical picture in a case that we reported as Ayerza's disease in a twelve-year-old girl. She also had black cyanosis, with a marked cor pulmonale, perfectly normal lungs, atheromas in the major arteries, but no obstructive vascular lesions whatever. This syndrome occurs without any question.

DR KING At this age?

DR MALLORY No. I should think that that is quite unusual.

DR MEANS Could the atheromatous process interfere with the elasticity of the artery sufficiently to cause an embarrassment, hemodynamically speaking, to the flow of blood through the pulmonary circuit?

DR MALLORY There is little direct relation be-

like a typical history because he had no history of previous bladder disturbance

I cannot see how the past history would have any definite bearing on the present trouble. The gonorrhea might possibly have resulted in a stricture of the urethra, but I do not believe that the stricture of the urethra in and of itself could cause the situation I have just read or that the bleeding peptic ulcer would influence the situation. We do not know what kind of ulcer it was. It might have been malignant, but that was ten years ago and, if it were malignant, I do not believe he would have been so well as he was when he came in.

"The blood pressure was 152 systolic, 104 diastolic." He was a man of fifty-four and that might be high but perhaps not incompatible with his age. Nowadays one must think of renal hypertension, but I am not aware that it is necessarily accompanied by the symptoms about which we have been reading.

I should like to know what the rectal examination showed besides the hemorrhoids. There might have been something wrong with the prostate. It might have been nodular, irregular and large, or perhaps there was induration at the bladder base, which might help in saying that he had a carcinoma of the prostate or possibly a malignant neoplasm of the bladder.

The white-cell count would go with some urinary infection, probably due to urinary back pressure. He also had evidence of some trouble involving the right kidney. I should say that the disease from which he sought relief had not made much change in the kidney function, at least on one side. It certainly had not lowered the hemoglobin and red count much if at all, and the chemical findings in the blood show that the kidneys were functioning quite well, and I should say that the blood calcium and phosphorus are not indicative of hyperparathyroidism. The x-ray findings and the fact that, on cystoscopy, the right ureter was bulging indicate the possibility of a ureteral stone. However, it might have been a neoplasm, or a blood clot that came down to that point.

We then find that a catheter could be passed all the way up to the kidney without difficulty, a fact which suggests that the object seen in the x-ray film had disappeared. A blood clot for instance, might easily have gone to pieces and passed down the ureter, or it may have been a stone that was pushed back or went back into the kidney by retrograde peristalsis. It might still have been a neoplasm in the ureter. The fact that he had *Staphylococcus albus* in the urine implies that the first cystoscopy had introduced it because the urine was previously negative. That is not an

uncommon result. It might also be that the stone, if it were a stone, was there and that the ureter was dilated enough so that the catheter passed by without evidence of obstruction—a not uncommon finding.

These filling defects in the kidney pelvis might have been due to a stone or to a neoplasm of the pelvis of the kidney rather than one in cortical substance. These defects might also simply have been due to blood clots from previous hematuria.

The x-ray findings do not rule out, but help to rule out, the possibility of a cortical neoplasm. Such a growth would probably form a mass or a bulge of some sort in the kidney.

"In the lateral film the mass extended downward to the region of the middle calyx, and the calyx lay mainly posterior." That is hard to explain. The lesion might be due to stone or to a pelvic neoplasm such as I have described, or again it might be due to blood clot.

I have mentioned various things, and because I do not like to leave anything out, I should like to mention also the possibility of infarct of the kidney. Such a lesion is rare but is one which might produce some of the symptoms which we have read about. It is obvious that the trouble was in the right kidney, and I shall include also the right ureter. We have first to think of the possibilities of neoplasm, for a neoplasm of the pelvis of the kidney with blood clots would give some of the filling defects that are seen in the ureter and kidney pelvis. We have to think strongly of ureteral neoplasm, but the one case I have had personally and the other few I have heard about produced permanent obstruction to the passage of the catheter up the ureter. While I do not think this lesion can be ruled out I think it is unlikely. I believe we can rule out tuberculosis on the evidence at hand. I think we probably can rule out hemorrhagic nephritis. I cannot really exclude it because I remember one case which we mistook for one of kidney tumor. The patient had hematuria, pain, and so forth, the pain being due to blood clot which was retained in the kidney. So my diagnosis is (1) pelvic neoplasm with blood clots, (2) renal stone which at one time might have become ureteral, and (3) ureteral neoplasm, probably primary. Either of these three things—stone or neoplasm of the kidney pelvis or ureter—would account for the blood clots which would cause the filling defects that were described.

DR FLETCHER H COLBY. In discussing this case I ask you, in the first place, to notice that the patient had three admissions to the hospital, so we were in considerable doubt as to the diagnosis, even with the added information that we had from seeing the patient, doing the cystoscopic examinations and personally studying the x-ray films

Ten years prior to entry he was treated in an outside hospital for bleeding peptic ulcer

Physical examination showed a well-developed and nourished man in no distress. Examination of the head and chest was negative. The blood pressure was 152 systolic, 104 diastolic. The abdomen was negative. There was slight costo-vertebral tenderness on the right. Rectal examination showed tender external hemorrhoids.

The temperature was 101°F., the pulse 100, and the respirations 20.

The urine showed a trace of albumin and contained many white cells and red cells, the specific gravity was 1.020, and culture showed no growth. A phenolsulfonephthalein kidney-function test was normal. The blood showed a red-cell count of 4,700,000 with 85 per cent hemoglobin, and a white-cell count of 6600. The nonprotein nitrogen of the blood serum was 35 mg per 100 cc, the sugar 101 mg, the calcium 10.46 mg, the phosphorus 3.84 mg and the uric acid 4.4 mg. A blood Hinton test was negative.

A retrograde pyelogram showed slight diffuse dilatation of the right kidney pelvis, calices and ureter. The ureteral dilatation ended abruptly just below the sacroiliac joint, where there was a rounded filling defect having the appearance of a stone. Three days later another retrograde pyelogram showed slight dilatation of the entire right ureter, but the rounded defect previously described was no longer visible. Cystoscopic examination on the day of admission showed a prominent reddened ureteral orifice on the right, and grossly bloody urine came from the right ureter.

On the fourth hospital day the patient was much improved. He had not complained of any acute symptoms since entry. Only an occasional red cell was seen in the urine. He was discharged on the eighth hospital day.

**Second Admission** (one month later). Three days after discharge he again had hematuria, with no associated pain. This promptly ceased, but three days later recurred. He then had intermittent hematuria until entry. He had had slight pain in the right costo-vertebral angle, but no severe paroxysm.

The physical examination showed no change since the previous admission.

On the second hospital day, cystoscopic examination showed slight injection of the trigone. A No. 6 catheter was easily passed to the right kidney, and bloody urine, soon followed by clear urine, was obtained. A culture of this showed *Staphylococcus albus*. He was discharged on the sixth hospital day.

**Third Admission** (two weeks later). The patient had had no further hematuria but had had

an occasional twinge of pain in the right flank. The physical examination was unchanged.

The temperature was 98, the pulse 80, and the respirations 20.

Urine examination showed a slight trace of albumin and 30 red cells per high-power field.

A retrograde pyelogram showed an abnormal upper calyx of the right kidney, characterized by a non-opaque filling defect 1.5 cm in diameter. This was surrounded by dye. The lower calyx showed a less marked, indefinite deformity. The ureter was normal.

On the third hospital day a retrograde pyelogram following peri-renal air injection on the right side showed the kidney outline very well demonstrated with no deformity. There was a mass in the region of the upper calyx which spread the latter apart. In the lateral film the mass extended downward to the region of the middle calyx and the calyx lay mainly posteriorly.

On the following day another retrograde pyelogram showed the same defect to be present. On the sixth hospital day an intravenous pyelogram with the film taken after blocking the ureter with a Dourmashkin bag showed increased density of the right kidney. There was no variation in the density in the region of the mass previously described. Its degree of opacity was the same as that of the remainder of the kidney. Only a minute amount of dye was visible in the pelvis.

On the ninth hospital day an operation was performed.

#### DIFFERENTIAL DIAGNOSIS

**DR J. DELLINGER BARNEY** With this story, so far as it goes, one can think of a number of conditions that might cause the symptoms which have been described. He might have had a neoplasm of the bladder, which can give hematuria without any other symptom. He might have had a tumor of the kidney which would explain some of the renal symptoms which he had and also the blood. He might have had a stone in the bladder which might account for the blood but probably not, it is not common with bladder stone to see diffuse hematuria and also there is usually a history of more or less long-continued urinary trouble, frequency, irritability, and so forth. He might have had a renal or ureteral calculus which might produce the bladder symptoms and the hematuria and readily account for the pain, as well as the nausea, vomiting, and so forth. He might have had primary neoplasm of the ureter which would cause obstruction, hematuria and colic and all the other symptoms he had. One should not leave out the possibility of tuberculosis of the kidney, although it does not sound

like a typical history because he had no history of previous bladder disturbance.

I cannot see how the past history would have any definite bearing on the present trouble. The gonorrhea might possibly have resulted in a stricture of the urethra, but I do not believe that the stricture of the urethra in and of itself could cause the situation I have just read or that the bleeding peptic ulcer would influence the situation. We do not know what kind of ulcer it was. It might have been malignant, but that was ten years ago and, if it were malignant, I do not believe he would have been so well as he was when he came in.

"The blood pressure was 152 systolic, 104 diastolic." He was a man of fifty-four and that might be high but perhaps not incompatible with his age. Nowadays one must think of renal hypertension, but I am not aware that it is necessarily accompanied by the symptoms about which we have been reading.

I should like to know what the rectal examination showed besides the hemorrhoids. There might have been something wrong with the prostate. It might have been nodular, irregular and large, or perhaps there was induration at the bladder base, which might help in saying that he had a carcinoma of the prostate or possibly a malignant neoplasm of the bladder.

The white-cell count would go with some urinary infection, probably due to urinary back pressure. He also had evidence of some trouble involving the right kidney. I should say that the disease from which he sought relief had not made much change in the kidney function, at least on one side. It certainly had not lowered the hemoglobin and red count much if at all, and the chemical findings in the blood show that the kidneys were functioning quite well, and I should say that the blood calcium and phosphorus are not indicative of hyperparathyroidism. The x-ray findings and the fact that, on cystoscopy, the right ureter was bulging indicate the possibility of a ureteral stone. However, it might have been a neoplasm, or a blood clot that came down to that point.

We then find that a catheter could be passed all the way up to the kidney without difficulty, a fact which suggests that the object seen in the x-ray film had disappeared. A blood clot, for instance, might easily have gone to pieces and passed down the ureter, or it may have been a stone that was pushed back or went back into the kidney by retrograde peristalsis. It might still have been a neoplasm in the ureter. The fact that he had *Staphylococcus albus* in the urine implies that the first cystoscopy had introduced it because the urine was previously negative. That is not an

uncommon result. It might also be that the stone, if it were a stone, was there and that the ureter was dilated enough so that the catheter passed by without evidence of obstruction—a not uncommon finding.

These filling defects in the kidney pelvis might have been due to a stone or to a neoplasm of the pelvis of the kidney rather than one in cortical substance. These defects might also simply have been due to blood clots from previous hematuria.

The x-ray findings do not rule out, but help to rule out, the possibility of a cortical neoplasm. Such a growth would probably form a mass or a bulge of some sort in the kidney.

"In the lateral film the mass extended downward to the region of the middle calyx, and the calyx lay mainly posterior." That is hard to explain. The lesion might be due to stone or to a pelvic neoplasm such as I have described, or again it might be due to blood clot.

I have mentioned various things, and because I do not like to leave anything out, I should like to mention also the possibility of infarct of the kidney. Such a lesion is rare but is one which might produce some of the symptoms which we have read about. It is obvious that the trouble was in the right kidney, and I shall include also the right ureter. The white-cell count would go with some urinary infection, probably due to urinary back pressure. He also had evidence of some trouble involving the right kidney. I should say that the disease from which he sought relief had not made much change in the kidney function, at least on one side. It certainly had not lowered the hemoglobin and red count much if at all, and the chemical findings in the blood show that the kidneys were functioning quite well, and I should say that the blood calcium and phosphorus are not indicative of hyperparathyroidism. The x-ray findings and the fact that, on cystoscopy, the right ureter was bulging indicate the possibility of a ureteral stone. However, it might have been a neoplasm, or a blood clot that came down to that point.

We then find that a catheter could be passed all the way up to the kidney without difficulty, a fact which suggests that the object seen in the x-ray film had disappeared. A blood clot, for instance, might easily have gone to pieces and passed down the ureter, or it may have been a stone that was pushed back or went back into the kidney by retrograde peristalsis. It might still have been a neoplasm in the ureter. The fact that he had *Staphylococcus albus* in the urine implies that the first cystoscopy had introduced it because the urine was previously negative. That is not an

uncommon result. It might also be that the stone, if it were a stone, was there and that the ureter was dilated enough so that the catheter passed by without evidence of obstruction—a not uncommon finding.

These filling defects in the kidney pelvis might have been due to a stone or to a neoplasm of the pelvis of the kidney rather than one in cortical substance. These defects might also simply have been due to blood clots from previous hematuria.

The x-ray findings do not rule out, but help to rule out, the possibility of a cortical neoplasm. Such a growth would probably form a mass or a bulge of some sort in the kidney.

'In the lateral film the mass extended downward to the region of the middle calyx, and the calyx lay mainly posterior.' That is hard to explain. The lesion might be due to stone or to a pelvic neoplasm such as I have described, or again it might be due to blood clot.

I have mentioned various things, and because I do not like to leave anything out, I should like to mention also the possibility of infarct of the kidney. Such a lesion is rare but is one which might produce some of the symptoms which we have read about. It is obvious that the trouble was in the right kidney, and I shall include also the right ureter. We have first to think of the possibilities of neoplasm, for a neoplasm of the pelvis of the kidney with blood clots would give some of the filling defects that are seen in the ureter and kidney pelvis. We have to think strongly of ureteral neoplasm, but the one case I have had personally and the other few I have heard about produced permanent obstruction to the passage of the catheter up the ureter. While I do not think this lesion can be ruled out I think it is unlikely. I believe we can rule out tuberculosis on the evidence at hand. I think we probably can rule out hemorrhagic nephritis. I cannot really exclude it because I remember one case which we mistook for one of kidney tumor. The patient had hematuria, pain, and so forth, the pain being due to blood clot which was retained in the kidney. So my diagnosis is (1) pelvic neoplasm with blood clots, (2) renal stone which at one time might have become ureteral, and (3) ureteral neoplasm, probably primary. Either of these three things—stone or neoplasm of the kidney pelvis or ureter—would account for the blood clots which would cause the filling defects that were described.

DR FLETCHER H COLBY. In discussing this case I ask you, in the first place, to notice that the patient had three admissions to the hospital, so we were in considerable doubt as to the diagnosis, even with the added information that we had from seeing the patient, doing the cystoscopic examinations and personally studying the x-ray films.

Dr Barney has had the help of none of these things. The x-ray diagnosis suggested the presence of stone in the ureter. One thing that is not in this history is that a waxed-tipped bougie was passed up the right ureter and no scratches obtained. That is a delicate diagnostic procedure, and I think almost never can a stone be present in the ureter and a waxed-tipped catheter be passed by without scratches being obtained. So we were certain that ureteral calculus could be eliminated and that, as Dr Barney shrewdly observed, it was blood clot in the ureter which had caused the filling defect. The diagnosis was not arrived at until the retrograde pyelograms were done, with perirenal infiltration of air around the kidney.

DR RICHARD C BATT I shall not take time to repeat what has already been said in the x-ray report. I shall just point out that the air injection around the kidney shows up very nicely, and here is the deformity in the pelvis, which is also very apparent. The urologists have studied these types of lesions much more thoroughly than I have.

DR COLBY Dr Oliver Cope and Dr Howard I Suby visualized the outline of the renal parenchyma very well, and there was no irregularity in outline of the upper pole of the kidney to suggest solid growth of the kidney itself. However, when the film was examined carefully it was easy to see a deformity of the upper calyx which was apparently due to compression and which we considered to be caused by a solid tumor of the upper pole of the kidney. I think it is only fair for Dr Barney to have a good look at the x-ray films.

DR GEORGE G SMITH May I make one remark? We really made the preoperative diagnosis very accurately in this case. In many of the pyelograms the lower half of the pelvis was obliterated, and yet with a good filling on retrograde pyelogram, the calices in the lower half

were intact. So we argued from that that there was an extension of growth down half the cortex of the kidney which must be pressing on the cavities of the kidney and which was held away from them by the retrograde injection. When the air injection was done we made a diagnosis of solid tumor involving the upper pole but also extending down through the cortex of the kidney.

#### CLINICAL DIAGNOSIS

Tumor of right kidney

#### DR BARNEY'S DIAGNOSIS

- (1) Tumor of pelvis of kidney
- (2) Renal calculus
- (3) Ureteral neoplasm

#### ANATOMICAL DIAGNOSIS

Renal-cell adenocarcinoma

#### PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY The urological surgeons have of course the most elaborate and most accurate set of instruments and diagnostic measures for examining their patients of any specialists in medicine. The result is that their diagnoses are generally so accurate before operation that cases are seldom of much interest to discuss at clinics of this sort. It is the exceptional case where there is really a great deal of doubt at the time they decide to operate on their patient.

This man was operated on and at exploration it was possible to feel the definite tumor in the upper part of the kidney. The kidney was resected without difficulty. On section in the laboratory the clinical prognostications were completely fulfilled. There was a spherical mass in the upper pole from which extended a tongue-like projection downward through the cortical substance, two thirds of the way to the lower pole. At one point the upper calyx was invaded, this provided a source for the hemorrhage.

## SYMPOSIUM ON VIRUS AND RICKETTSIAL DISEASES

STUDENTS of infectious disease are living, at the present time, in an era which is comparable in rapidity of discovery and intellectual adventure to that which transformed medicine in the period between Pasteur and Ehrlich. Ultramicroscopic virus agents have of course been known for a very long time—indeed, ever since the observation of tobacco mosaic in 1892 and the discovery of an invisible agent as the cause of foot and mouth disease in 1897. There was in the ensuing years a natural tendency among investigators to assume the possibility of filterable agents in almost all diseases which were obviously infections, but in which bacterial causation could not be determined. It was not until 1920 that the subject began to de-

velop precision, but in the subsequent nineteen years not only have innumerable diseases of animals and man been conclusively linked with virus causation, but special technics have been devised for virus study by which determination of size and chemical constitution was made possible. Methods of tissue culture have enabled investigators to study individual virus agents in the laboratory, their relations to tissue cells and to cell metabolism, and, to some extent, the immunological reactions they arouse in infected animals. The field has expanded in such a way that it now holds a place as important in medicine as bacteriology itself, and since many of the conditions now known to be caused by these ultramicroscopic agents are among the most important known epidemic diseases, there has developed, at the same time, a special epidemiology to which methods of virus investigation are applicable—not least important among them the problem of the curious preparatory relation of some virus infections to secondary bacterial invasion, as in measles and influenza.

Nothing could be more timely for men in the professions of medicine and of public health than a thorough review of the virus and rickettsial diseases, such as will be held under the auspices of the Harvard School of Public Health during the week of June 12 to 17. Within the past year New England has been confronted with a new experience in virus disease—the human cases of equine encephalitis—and with a rickettsial disease,—Rocky Mountain spotted fever,—familiar in the West but previously unknown in this region.

The problem of keeping abreast of the rapid developments in the epidemiology, the immunology and the treatment of this whole group of diseases is beyond the power of practicing physicians without the assistance of such opportunities for review as these meetings will provide. Undoubtedly to many the Symposium will be very welcome. Details as to the program and registration will be found elsewhere in this issue of the *Journal*.

## CITY HOSPITAL TROUBLE

THE editorial with the above title, which appeared in the May 4 issue of *The Boston Herald*,

so ably expresses appreciation of the services that Joseph P Manning and Dr George G Sears, as trustees of the Boston City Hospital, have rendered for many years to the people of Boston, so strongly calls the attention of Mayor Tobin to his responsibility in appointing new trustees who are equally well qualified, and so fairly condemns the City Council for its frequent, and usually uncalled-for, attacks on the hospital administration, that it is herewith reprinted in full

Mayor Tobin will be fortunate if he can find two men as well qualified as Joseph P Manning and Dr George G Sears to act as trustees of the Boston City Hospital. The former had served for more than a quarter of a century and Dr Sears for twenty-one years. They were as conscientious in their attention to the affairs of the institution as if they received a large salary, instead of no recompense at all, for attendance at the weekly sessions of the board. They had become thoroughly familiar, of course, with the problems of administration. In spite of political pressure, to which they were compelled to give way at times, they made no compromises which impaired the technical excellence of the hospital. Mr Manning brought to the discussions of the board the experience which he had gained as a highly successful man-of-affairs. Dr Sears contributed professional judgment of a high quality.

The periodic attacks on the City Hospital have made the lot of the trustees uncomfortable. Trivial defects which could be corrected at once if called quietly to the attention of the board have been ballyhooed out of all proportion to their importance by councilors who wished to gain a few votes. Criticisms based on misunderstanding have been frequent. The good sense and competence of the trustees have been questioned without justification. This irritating sniping, which has been going on so long, was perhaps one of the causes of the resignations.

No board of public trustees, paid or unpaid, can reasonably expect to remain immune from rigorous examination and some harsh criticism. It is the duty of the councilors, the finance commission, the mayor, the budget commissioner and others to exercise authority over such groups. It is quite wholesome that they should be required to give accounts of their stewardship. But, in the case of the City Hospital, the hostility at City Hall has gone to indefensible extremes. If it continues there will inevitably be deterioration in the quality of the trustees, and that will be reflected quickly by a deplorable decline in the efficiency of the hospital itself.

Members of the council can prevent a development of this kind by withholding their fire until they are sure they are correct, and then by refraining from making political capital out of a little mistake in hospital administration.

#### BLEEDING IN THE PUERPERIUM

Mrs T H, a gravida II, at term, entered the hospital December 8, 1930, in active labor.

The family history was nonessential. Her past history was negative except for attacks of tonsillitis. The patient's first pregnancy was normal and was terminated by mid-forceps. Catamenia began at twelve, were regular with a twenty-eight-day cycle and lasted four days. Her last period was March 3, making her due for delivery December 10. The present pregnancy had been normal throughout.

Examination after admission showed that the membranes had ruptured, the vertex was presenting in the OLA position. Labor was very rapid and in three hours the baby, weighing 8 lb., 11 oz., was delivered normally. Shortly after delivery bleeding began and the placenta was expressed. The patient was given ergot and posterior pituitary extract and the head of the delivery table was lowered, as her pulse was 160 and of poor quality. She was returned to her room in an hour, the pulse was 136 and of fair quality. An ice bag was applied to the fundus. One hour later, two hours after delivery, her condition was not good, and she became restless and irrational. The pulse was 110. The patient improved slowly but was very weak. She continued to flow bright red blood, and at 8 00 a m on December 21, thirteen days after delivery, she expelled a clot. At 10 a m the same day a large clot was expressed; the patient felt weak and her pulse was 120. Another clot was expressed at 10 20 p m, and she continued to expel small clots until the next morning when another large clot was expressed. At this time the patient's pulse was 160 and very weak.

Blood examination at this time showed a hemoglobin of 45 per cent, a red blood-cell count of 2,480,000 and a white-blood-cell count of 12,700. A consultant was called, and after her blood had been typed, she was transfused by the direct method with 600 cc of blood. At the conclusion of the transfusion her pulse had improved and the

A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

blood pressure was 100 systolic, 80 diastolic. She was prepared for vaginal examination, and a piece of placenta the size of an orange was removed with the fingers. The uterus was washed out with normal saline, followed by alcohol, and packed tightly to the fundus. The pack was removed in twenty-four hours, and she was then given saline and alcohol intrauterine douches. The patient was discharged on the thirtieth postpartum day, with a hemoglobin of 75 per cent, a red-blood-cell count of 4,000,000 and a white-blood-cell count of 7000.

*Comment* Procrastination is often intelligent sometimes fatal. The evidence of the continued bleeding after the birth of this baby should have been recognized as abnormal and the uterus should have been explored much sooner than it was. Severe hemorrhage did not occur until thirteen days after delivery, but before that time there had been much more than a normal amount of flowing every day.

The treatment when the consultant was called is praiseworthy. No attempt was made to enter this uterus until after transfusion had been accomplished. The large piece of placenta was readily found and removed. This uterus was washed with normal saline and alcohol—a common performance in 1930 but one that is seldom employed today—and then packed. It is wise not to leave a pack in the uterus longer than twenty-four hours, and today most people would not follow the removal of the pack with an intrauterine douche. It is also barely possible that had posterior pituitary extract been used intravenously when the first bleeding occurred soon after the birth of the baby, this piece of placenta might have been extruded, however, relatively large pieces of retained placenta are usually somewhat adherent. The aftercare of patients that have bled freely should consist of an anemia diet, large doses of some preparation of ferrous sulfate, and fresh air and sunlight.

#### DEATHS

**AHLSTROM**—**HJALMAR AHLSTROM, M.D.**, died in February 1939. He was in his seventy-seventh year.

Dr Ahlstrom received his degree from Tufts College Medical School in 1911. He was a member of the American Medical Association and the Massachusetts Medical Society.

**KELLOGG**—**FREDERIC L. KELLOGG, M.D.** of 350 Commonwealth Avenue, Boston, died May 2. He was in his seventy-third year.

Dr Kellogg received his degree from the Bellevue Hospital Medical College, New York City, in 1889. He was

a member of the Massachusetts Medical Society and the American Medical Association.

## MISCELLANY

### NEW ENGLAND MEDICAL CENTER

On Wednesday afternoon, May 10, a reception was given by the Trustees of Tufts College at the Joseph H. Pratt Diagnostic Hospital of the New England Medical Center, as one of the activities of the recently inaugurated Tufts College Medical School Development Program. From two until four the guests were shown the activities of the New England Medical Center, under the guidance of students of Tufts College Medical School. These included visits to the various departments of the Joseph H. Pratt Diagnostic Hospital, the Boston Dispensary and the Boston Floating Hospital.

Tea was served in the library of the Diagnostic Hospital from three until four and was followed by series of short addresses in the auditorium. The speakers were Mr. Henry Parkman, Jr., chairman of the Tufts College Medical School Development Program; Governor Leverett Saltonstall, Mr. Leonard Carmichael, president of Tufts College, and Mr. Barry Smith, director of the Commonwealth Fund, New York City.

#### NOTE

The appointment, effective this fall, of Dr. Tracy J. Putnam as professor of neurology and neurosurgery at Columbia University College of Physicians and Surgeons and director of the services of neurology and neurosurgery at the Neurological Institute of the Columbia-Presbyterian Medical Center has been recently announced. Dr. Putnam is at present professor of neurology at Harvard Medical School and director of the Neurological Unit of the Boston City Hospital.

## CORRESPONDENCE

### EMERGENCY CALL FOR A WOMAN DOCTOR IN INDIA

*To the Editor* The Woman's Hospital at Gauhati, Assam, is in urgent need of a woman doctor. Located among the hill tribes in this province of northeastern India, this hospital has a unique opportunity. Until recently it had two American women doctors, but one has left to be married and the other has fallen ill. There are two American nurses on the staff, two Indian women physicians, eight Indian staff nurses and twenty-six nurses in the training school. The hospital has 45 beds and during 1938 cared for 700 inpatients. One hundred and forty operations were done during 1938, and the woman doctor now sought should be able to do surgical work. Laboratory and x-ray equipment is available.

This hospital is under the Woman's American Baptist Foreign Mission Society, which has carried on its work in India for the past century. Applications and inquiries should be addressed to the Christian Medical Council, 156 Fifth Avenue, New York City, or to Miss Hazel F. Shank, 152 Madison Avenue, New York City.

EDWARD F. HUMIE, M.D., *Director*  
Christian Medical Council  
for Overseas Work.

156 Fifth Avenue,  
New York City

## REPORTS OF MEETINGS

## WILLIAM HARVEY SOCIETY

At a meeting of the William Harvey Society of Tufts College Medical School on Friday, January 20, in the Beth Israel Hospital auditorium, Dean A. Warren Stearns introduced the speaker of the evening, Dr Stanley Cobb, whose subject was "Neurosis and Hysteria."

Dr Cobb introduced his subject by defining its importance and its limitations. General practitioners have stated that one third of their practice is concerned with acute infections, one third with chronic medical and surgical diseases and one third with what they term "functional disease," meaning thereby the neuroses. The word "neurosis" literally means "full of nerves," which obviously signifies nothing to us in this day and age. That the term means there is "nothing the matter" with the patient is untrue, a man with a neurotic symptom who asks for medical help is not to be sent away with a laugh just because physical examination and laboratory studies reveal nothing pathological. Perhaps, in the ultimate analysis, one may say that the neuroses belong in the field of neurology, by reason of the fact that they are outwardly expressed in terms of the neuromuscular system and inwardly in terms of the autonomic nervous system. The latter is often as expressive as the former, and it should be as much a part of the doctor's understanding. The sum total expression of the two systems is classed as "behaviour."

Dr Cobb's thesis for the evening was a systematic classification of the problems relative to the neuroses. The first or simplest form of neurosis he termed "exaggeration of the normal." This is a well known phenomenon to all and is a common experience in life. The palpitation, sweating, dryness of mouth, trembling, and so forth, of one who must stand before an audience is called normal. However, in some cases it may be manifestly extreme, such as in the neurotic individual who is seriously disturbed by frequent attacks of syncope. These exaggerations are often conditioned reflexes of special association, and a very common mode of expression is through the autonomic system, especially the gastrointestinal tract and the cardiorespiratory system.

The next type, in increasing degree of complexity, is the "anxiety neurosis," on which Dr Cobb has directed his special attention the past several years. The term should be applied only to one syndrome—to individuals who are anxious and have symptoms referable to the heart, lungs, chest and neck, taking the form of hyperventilation, rapid heart, a feeling of strangulation and not uncommonly a radiating heart pain indistinguishable from angina. These individuals, however, have perfectly normal hearts, lungs and thyroid glands.

The third form of neurosis is the "phobia," which is a symptom of anxiety but more specifically expressed and localized than the type described above. A special situation is required with specific associations.

Next comes "hysteria" as a special form. The term is often misused, the original meaning was "wandering uterus," in the sense that symptoms were variably referable to whatever organ or structure was the settling place of the wandering uterus at the moment. Dr Cobb believes hysteria should be reserved for a definite syndrome. He presented lantern slides abstracting ideas of several famous psychiatrists. Janet called it "retraction of the field of consciousness and dissociation," which is rather too abstract a definition for most of us to fathom. Babinski said it can be produced and relieved by suggestion, which Dr Cobb does not believe to be quite true. Adolph Meyer defines it as a condition occurring in individuals

who are somewhat limited and have something abnormal in their memory fields, and who develop medical or neurological symptoms as a result of their failure in dealing properly with an emotional problem at some early time. Such persons have an actual conversion of the anxiety into an overt symptom.

Dr Cobb presented a case report of a patient in this category. A nineteen year-old girl was first seen in a marked state of alkalosis, with hyperpnea and tetany. The maximum respiratory rate was 140 per minute, and the maximum pulse rate 140. At the time that these readings were noted, the pulse beats and respiratory movements were synchronous. She had a basal metabolic rate of +53 per cent, whereas under hypnosis, which relieved her condition, her normal was -11 per cent. The pH of her blood was 7.61, she ventilated 40 liters per minute, the normal mean ventilation being 5 to 7 liters. Dr Cobb suggested that it is useless to call this either organic or functional disease, it should rather be considered as being both, or a *ratio in equilibrio*.

The patient's history presented several possible early emotional experiences. She was underdeveloped, with respect to appearance, and had a small uterus. Such "baby doll" types are quite common among women, they know they are attractive and therefore their ideology is concerned with this fact. This is a characteristic of hysterical patients. All have an amnesia of the original cause of their present symptoms. It can be said that average men and women, if they had had similar emotional experiences earlier in life, might have developed similarly. Hysterical symptoms are called by Meyer "pseudoneurological," because they are expressions of either the neuromuscular or autonomic systems, or both. The hyperventilation described in this case was necessarily a mixture of both.

"Exaggeration of the normal," "anxiety neurosis" and "phobia" are forms of neuroses which can be grouped as coming under the autonomic or visceral sphere, and patients with such neuroses usually come to the medical wards. On the other hand, the next three classifications—"compulsion neurosis," "hypochondriasis" and "rumination tension"—are more truly in the sphere of psychology. Lastly, "dementia praecox" and the "depression psychoses" are true psychoses. This classification illustrates gradations of increasing involvement, increasing divergence from the normal, and an increasingly unfavorable prognosis as one goes down the list.

Dr Cobb concluded his presentation with the statement that, as in all the sciences, there must be a first or descriptive period, so in psychiatry we are still collecting and describing, and perhaps just beginning to go on to the second period—to work on the problems of the underlying mechanism.

## HARVARD MEDICAL SOCIETY

At a meeting of the Harvard Medical Society on Tuesday, January 24, in the amphitheater of the Peter Bent Brigham Hospital, Drs Merrill C. Sosman and Samuel A. Levine gave a presentation on the subject "Some Clinicoroentgenological Correlations, using case records and roentgenograms for illustration and confining their remarks to the heart, lungs and esophagus."

Dr Levine stated that the thesis for the evening was, "To make clearly understandable the limitations of both clinical and roentgenological methods." He said that in some cases the x-ray film is of no material assistance, whereas in other cases diagnosis and even the plan of treatment depend on it, and that the same holds true for physical examination.

The first case illustration concerned a fifty-eight-year-old man, who came in with a history of typical anginal distress, marked on effort, of several months duration. At discharge, his heart was clinically normal and in good condition, the x-ray findings confirmed this, the heart being normal in size. Two years later he returned with increased symptoms, and the x-ray findings included enlargement of the heart to the left and parallel areas of calcification in the coronary arteries. The patient underwent a total thyroidectomy, following which the heart showed a still further increase in diameter. The appearance was typical of myxedema, and after treatment with thyroid extract, the heart measurements decreased. The patient did very well for the next four years, then his attacks returned, and he died soon after. At autopsy, the calcified coronary artery walls were well demonstrated.

In this case the physical examination and x-ray examination were at first negative, the diagnosis depended on the history. Later, the x-ray films did show calcified coronaries. However, one may have calcification of the coronary arteries without angina pectoris, and vice versa. The x-ray, then, merely offered evidence incriminating the heart, and the case illustrated that angina must be diagnosed from the history and not from x-ray study. It was added that, in recent years at this hospital, thyroidectomy had not been performed because it was concluded that patients so treated became a great burden to themselves and later developed recurrences which were very difficult to treat.

The second case history was that of a sixty-three-year-old man, who complained of angina. He had pain and a choking sensation in his throat lasting from three to fifteen minutes and radiating down the sternum. However, effort and walking even in the coldest weather caused no pain. Physical examination revealed a heart slightly enlarged to percussion, an aorta large enough to be percussible (both of these findings Dr Levine had to admit meant little), a Grade I systolic murmur at the base, and a definitely visible pulsation at the base of the neck on the right. His blood pressure was 140 systolic, 80 diastolic. It was fairly certain the patient did not have angina pectoris, but what he did have was the problem.

X-ray examination revealed marked dilatation of the ascending, transverse and descending aorta. It was called "aneurysmal," but pulsations were absent. Dr Sosman stated that the absence of pulsations does not rule out aneurysm, but that their presence does not necessarily mean aneurysm. The x-ray film also disclosed enlargement of the heart, but in a backward direction such that it was inconceivable that it had been picked up by percussion.

The patient suddenly died five or six years later of rupture of the aneurysm into the pleura, he had never had "angina." Dr Levine stressed the facts that syphilitic aortitis does not produce pain except by occlusion of the coronaries or by erosion of the bones due to pressure from the aneurysm and that the aortic insufficiency in such patients does not give the pain of angina. Simple evidence for this is that in the South, where aortic insufficiency is so common, patients of this type do not have anginal symptoms. This case illustrates the great importance of x-ray study in the diagnosis of aneurysm of the aorta.

The third case was that of a sixty-six-year-old man, who, for six months, had had dyspnea on exertion, and later even at rest, and cough with the production of sputum. Physical examination revealed an enlarged heart, distant sounds, premature beats, a Grade II systolic murmur at the apex, a diastolic murmur, gallop rhythm, edema, an enlarged liver, and rales at both lung bases. The blood pressure was 145 systolic, 96 diastolic. The di-

agnosis was questionable syphilitic aortitis with aortic insufficiency. The x-ray films showed ventricular hypertrophy, and calcification in the aortic valve as seen in the oblique view. The latter, according to Dr Sosman, is usually a sign of rheumatic heart disease and has not been found in syphilis.

Dr Levine brought out the fact that in suspected syphilitic heart disease 80 per cent of the patients have a positive Wassermann test. Of the 20 per cent with negative tests, if the x-ray film shows calcification in the valve, then the lesion is of rheumatic etiology. This case illustrates the value of finding calcification of the aortic valve in ruling out the diagnosis of syphilis.

The fourth case was that of a nurse who came in for x-ray study of the chest more in jest than for any indication. The film showed the typical picture of rheumatic mitral disease with slight pulmonary congestion. Dr Levine had found a clear-cut, but faint, presystolic murmur, and obtained a meager history of chorea. The patient was symptom free for seven more years, then had dyspnea, and so forth, of a fulminating type. X-ray examination this time showed a much larger heart, and increased pulmonary congestion, which is often interpreted as rheumatic pneumonia. She died abruptly within a few months.

X-ray study having been the means of diagnosis in this case, Dr Sosman cannily asked Dr Levine if it were possible to have mitral stenosis without a murmur. Dr Levine countered by saying "Possibly, but almost never, whereupon Dr Sosman demonstrated roentgenograms showing a very large left auricle in a case in which Dr Levine had been unable to find a diastolic murmur. According to Parkinson, of London, x-ray examination revealing a large left auricle is the second most important sign of mitral stenosis. The inferences from these experiences were that auscultation of the heart is the most important method in the diagnosis of mitral stenosis, but that occasionally x-ray study is indispensable.

The fifth case was that of a fifty-three-year-old woman who had a history of palpitation and ascites of two years' duration. Her blood pressure was 160 systolic, 84 diastolic, her heart was slightly enlarged, with regular gallop rhythm, no murmurs, an electrocardiogram showing low voltage in the ventricular complexes, edema and a negative blood Wassermann test. A satisfactory diagnosis could not be made.

X-ray examination revealed marked cardiac enlargement and a dense shell of calcification all around the heart but more pronounced on the right, findings typical of constrictive pericarditis. Dr Sosman demonstrated kymograms of a similar case to show the improvement as measured by heart-border excursion after operation. In the present case, however, since the patient was comfortable and the progress of the disease very slow, it was thought that the risk of operation was not warranted. It was stated that some cases of calcification do not show constriction.

Dr Levine prefaced the discussion of congenital hearts by comparing congenital with acquired heart disease in general terms. The cyanosis of the former is the result of right-to-left shunting of the blood, whereas in the latter type it is due to poor aeration in the lungs as well as peripheral dilatation of the venules. In acquired heart disease, clubbed fingers occur only in subacute bacterial endocarditis, but are common in cyanosed patients with congenital heart disease. A loud murmur in a young patient is suggestive of the latter, and the electrocardiogram is of little use in diagnosis except in cases with dextrocardia and a few other rare anomalies. Polycythemia

is a common finding. Congenital hearts are subject to bacterial endocarditis, and have a high incidence of associated tuberculosis, mental deficiency and acquired rheumatic heart disease. Coarctation of the aorta and a patent ductus are relatively easy to diagnose, the tetralogy of Fallot and Rogers's disease and one or two other types are difficult but possible to diagnose.

Dr. Sosman then presented several roentgenograms illustrating these conditions. A right-arched aorta is demonstrated by the deviation of the esophagus; in adults, this may result in dysphagia lusoria. Coarctation could, at one time, be diagnosed only by the x-ray findings of a small aortic knob, moderate cardiac enlargement, notching of the ribs and a large supra-aortic saddle. It can be clinically suspected, now, where hypertension is found in youth. Dr. Levine emphasized how slight the coarctation may be, and how very easily missed. He suggested that one routinely feel of the femoral arteries in cases of hypertension, especially in youth. In coarctation the femoral pulse is very weak or absent. The hazard for these patients lies in heart failure, rupture, bacterial endocarditis or cerebral accident.

The sixth case was that of a sixty-eight-year-old man, who complained of dyspnea, pain in the chest and weakness of several weeks duration, not related to effort. Physical examination revealed a questionable mid-diastolic murmur, a rumble at the apex, dullness in the right axilla and at the right lung base, scattered bronchial squeaks, and rales not like those in heart failure. The diagnosis was questionable bronchiogenic carcinoma of the lung. The x-ray film showed atelectasis of the right middle lobe. Bronchoscopy established the diagnosis. X-ray therapy alleviated the pain, but the patient died a few months later. Radiation does not alter the course of the disease, but it is of definite value in the relief of pain. This case illustrated the fact that cancer of the lung may simulate heart failure.

The seventh case, that of an eighteen-year-old boy, who had a history of hemoptysis off and on over a period of ten months following an attack of grippe. Physical examination was negative except for a small area of dullness over the right lung base near the spine, which was unfortunately not taken seriously enough. The roentgenologist also missed the diagnosis at first, but on further consideration it was noted that the hilar shadow on the right side was less dense than normal. The entire lower lobe was atelectatic and pressed against the heart shadow. A diagnosis of a benign blocking tumor was made, and on operation a fetal bronchial adenoma was successfully removed.

The eighth case was that of a twenty-three-year-old woman, who had had pleurisy at the right base post partum. Four years later she came in complaining of being tired and listless and having lost 12 pounds. On physical examination it was stated that the lungs were clear and resonant. X-ray examination revealed an extensive pneumonic consolidation of the right base, consistent with an unsensitized type of tuberculosis, and also definite apical tuberculosis that was not picked up on physical examination.

This is one disease in which it matters a great deal whether the diagnosis is made early or late. A negative physical examination is an absolutely useless criterion of the presence or absence of pulmonary tuberculosis. In one series reported from Saranac, 15 per cent of the cases were negative to physical examination on entry, and this in a place where only a few of the entries had early forms of tuberculosis. X-ray study is of prime importance in this field.

At this point Dr. Sosman threw on the screen pictures of the shrine of St. Anne de Beaupre surrounded by crutches, braces, casts, and so forth, mute evidence of cures effected by faith, and then, drawing the analogy, pictured a corner of his x-ray laboratory with stethoscopes piled high in equally mute tribute to their uselessness in diagnosis!

The ninth case was that of a twenty-five-year-old woman, who had a story, of ten months duration, of an irregular fever of 102 to 103°F, with loss of weight and strength, stomatitis, pain in the flank, pelvis and lower quadrants, and night sweats. She had no cough. On physical examination she was found to have a Grade I apical systolic murmur, a few nodes in the axilla and groin, and tenderness in the right upper and left lower quadrants. Laboratory tests showed a hemoglobin of 57 per cent, a red-cell count of 4,000,000, and a white-cell count of 13,000 to 20,000. Various diagnostic possibilities were considered: tuberculosis, focal infection, and pelvic or renal disease.

By x-ray study she was shown to have a very slightly widened supracardiac shadow, which on fluoroscopy suggested a mass of lymph nodes behind the sternum. X-ray therapy resulted in a decrease in the shadow, and the temperature came down almost by crisis. For the three years since that time the patient has been perfectly well. Apparently the lesion was a localized type of Hodgkin's disease, and the alleviation is probably only temporary. It was stated that very few cases of Hodgkin's disease survive for more than five years, but that one case at the hospital had been followed for ten years. The type that promptly responds to radiation recurs just as rapidly. It was said that this case illustrated the use of x-rays as a method of diagnosis by therapeutic result, it was the sole method of diagnosis and treatment.

The tenth case was that of a sixty-one-year-old man, who had had pain in the chest and dyspnea for six months. The pain was described as pressing on the mid-sternum, usually coming on at night, and lasting several hours. The patient had had no disability on effort. He was admitted with a diagnosis of angina. Physical examination revealed a blood pressure of 128 systolic, 70 diastolic, a normal heart, limited chest expansion, diminished breath sounds, and bronchial squeaks and rales on inspiration and expiration, which were also audible at the front of the chest—findings not consistent with heart failure except in its most terminal stage. There was marked cyanosis. A diagnosis of questionable mediastinal obstruction was made.

Roentgenograms showed moderate enlargement of the mediastinal area, marked pulmonary emphysema and displacement of the trachea, first to the left, then to the right. The diagnosis was a substernal thyroid gland. On fluoroscopy, a typical thyroid plunge could be demonstrated when the patient was asked to cough. The trachea was also displaced forward by the retrotracheal extension of the non-toxic gland.

After operation, breathing was relieved, but as is usually the case, there remained chronic bronchitis and emphysema. Although clinically a mediastinal tumor was suspected, x-ray study more precisely established the diagnosis of thoracic goiter.

For their final case history Dr. Levine and Dr. Sosman presented an old case, that of a man who was forty-eight years old in 1920 and first came in for angina pectoris. He had pains in the midsternum which came on usually in the middle of the night and were unaffected by effort. He had been studied by almost every doctor and clinic in the United States and elsewhere at one time or another, with no success so far as the correct diagnosis or

treatment was concerned. Finally a roentgenogram taken during an attack of pain showed constriction of the esophagus, relieved by a drink of hot water. Esophagoscopy at first suggested carcinoma, then a benign adenoma, but finally a diagnosis of aberrant gastric mucosa and ulcer was made. Thereafter his course was not different from that of the average ulcer patient under treatment, and today he is alive and well at sixty six.

## NOTICES

### SYMPOSIUM ON THE VIRUS AND RICKETTSIAL DISEASES

The Faculty of the Harvard School of Public Health offers a short course of lectures, clinics, and demonstrations on the virus and rickettsial diseases, with special emphasis on their public health significance, to be held at the school during the week of June 12-17.

The fee for the course will be \$25.00, payable at any time up to June 12. Enrollment, however, should be arranged before June 1, as facilities for many of the clinics and demonstrations are limited. The lectures will be published later in a single volume, which will be sent to each person who has registered for the course.

The Registration Office in the Harvard School of Public Health will be open for registration Saturday and Sunday, June 10 and 11, from 9 until 5 o'clock. Persons attending the symposium are requested to register as promptly as possible after arriving in Boston.

Further information may be had by writing to the Secretary of the School of Public Health, 55 Shattuck Street, Boston.

The complete program follows.

\* \* \*

#### MORNING SESSIONS

Vanderbilt Hall

MONDAY, JUNE 12

*Presiding*—Dr. Cecil K. Drinker, dean and professor of physiology, Harvard School of Public Health

10 00-10 10 Greeting President James B. Conant.

10 10-10 45 Epidemiologic Problems in Virus Diseases. Dr. John E. Gordon, professor of preventive medicine and epidemiology.

10 45-11 30 Insects as Vectors of Virus Diseases. Lieut. Col. James S. Simmons, Medical Corps, U. S. Army, assistant corps area surgeon, Headquarters First Corps Area, Boston.

11 30-12 15 The Immunology of Infections by Filterable Virus Agents. Dr. Hans Zinsser, Charles Wilder Professor of Bacteriology and Immunology.

12 15-1 00 The Physical and Chemical Properties of Filterable Viruses. Dr. J. Howard Mueller, associate professor of bacteriology and immunology.

TUESDAY, JUNE 13

*Presiding*—Dr. Edwin H. Place, instructor in communicable diseases, Courses for Graduates, and physician-in-chief of the South Department, Boston City Hospital.

9 00-9 30 The Epidemiology and Control of Variola. Dr. Frederick F. Russell, professor of preventive medicine and epidemiology, emeritus.

9 30-10 00 Methods of Preparation and Use of Smallpox Vaccine Virus. Dr. Elliott S. A. Robinson, assistant professor of applied immunology and director of the Division of Biologic Laboratories, Massachusetts Department of Public Health.

10 00-10 15 Generalized Vaccinia. Dr. Ralph A. Ross, assistant in pediatrics.

10 15-10 30 Neurologic Complications of Vaccination. Dr. R. Cannon Eley, associate in pediatrics and communicable diseases.

10 30-10 45 The Etiology of Measles. Dr. John F. Enders, assistant professor of bacteriology and immunology.

Recess

11 00-11 40 The Prevention and Modification of Measles. Dr. Charles F. McKhann, associate professor of pediatrics and communicable diseases.

11 40-12 10 Administrative Problems in the Control of Measles. Dr. Harold D. Chope, instructor in public health administration and director of public health, Newton, Massachusetts.

12 10-1 00 Mumps: Its glandular and neurologic manifestations. Dr. Conrad Wesselhoef, associate in communicable diseases.

WEDNESDAY, JUNE 14

*Presiding*—Dr. Frederick F. Russell.

9 00-10 00 The Absorption of Toxic and Infectious Material from the Respiratory Tract. Dr. Cecil K. Drinker.

10 00-10 30 General Considerations of Virus Diseases of the Respiratory Tract. Dr. John A. Mote, associate in research, House of the Good Samaritan, Boston.

10 30-11 00 Distemper in Animals. Lieut. Col. Raymond A. Kelser, Veterinary Corps, U. S. Army, chief of Veterinary Division, Office of the Surgeon General, Washington, District of Columbia.

Recess

11 15-12 15 The Human and Swine Influenzas. Dr. John A. Mote.

12 15-12 45 Psittacosis. Dr. John F. Enders.

12 45-1 00 Lymphogranuloma Inguinale. Dr. Nels A. Nelson, lecturer on public health administration and director, Division of Genitoinfectious Diseases, Massachusetts Department of Public Health.

THURSDAY, JUNE 15

*Presiding*—Dr. Richard M. Smith, assistant professor of pediatrics and child hygiene.

9 00-9 30 The Epidemiology of Poliomyelitis. Dr. W. Lloyd Aycock, assistant professor of preventive medicine and hygiene.

9 30-9 50 The Clinical Features and Treatment of Poliomyelitis. Dr. Charles F. McKhann.

9 50-10 10 Poliomyelitis: A review of preventive measures. Dr. W. Lloyd Aycock.

10 10-10 45 The Classification of Encephalitis with a Consideration of Certain Epidemic Types. Dr. LeRoy D. Fothergill, Silas Arnold Houghton Assistant Professor of Bacteriology and Immunology.

is a common finding. Congenital hearts are subject to bacterial endocarditis, and have a high incidence of associated tuberculosis, mental deficiency and acquired rheumatic heart disease. Coarctation of the aorta and a patent ductus are relatively easy to diagnose, the tetralogy of Fallot and Rogers's disease and one or two other types are difficult but possible to diagnose.

Dr Sosman then presented several roentgenograms illustrating these conditions. A right-arched aorta is demonstrated by the deviation of the esophagus, in adults, this may result in dysphagia lusoria. Coarctation could, at one time, be diagnosed only by the x-ray findings of a small aortic knob, moderate cardiac enlargement, notching of the ribs and a large supra-aortic saddle. It can be clinically suspected, now, where hypertension is found in youth. Dr Levine emphasized how slight the coarctation may be, and how very easily missed. He suggested that one routinely feel of the femoral arteries in cases of hypertension, especially in youth. In coarctation the femoral pulse is very weak or absent. The hazard for these patients lies in heart failure, rupture, bacterial endocarditis or cerebral accident.

The sixth case was that of a sixty-eight-year-old man, who complained of dyspnea, pain in the chest and weakness of several weeks duration, not related to effort. Physical examination revealed a questionable mid-diastolic murmur, a rumble at the apex, dullness in the right axilla and at the right lung base, scattered bronchial squeaks, and rales not like those in heart failure. The diagnosis was questionable bronchiogenic carcinoma of the lung. The x-ray film showed atelectasis of the right middle lobe. Bronchoscopy established the diagnosis. X-ray therapy alleviated the pain, but the patient died a few months later. Radiation does not alter the course of the disease, but it is of definite value in the relief of pain. Four years later she came in complaining of being tired and listless and having lost 12 pounds. On physical examination it was stated that the lungs were clear and resonant. X-ray examination revealed an extensive pneumonic consolidation of the right base, consistent with an unsensitized type of tuberculosis, and also definite apical tuberculosis that was not picked up on physical examination.

This is one disease in which it matters a great deal whether the diagnosis is made early or late. A negative physical examination is an absolutely useless criterion of the presence or absence of pulmonary tuberculosis. In one series reported from Saranac, 15 per cent of the cases were negative to physical examination on entry, and this in a place where only a few of the entries had early forms of tuberculosis. X-ray study is of prime importance in this field.

At this point Dr Sosman threw on the screen pictures of the shrine of St. Anne de Beupre surrounded by crutches, braces, casts, and so forth, mute evidence of cures effected by faith, and then, drawing the analogy, pictured a corner of his x-ray laboratory with stethoscopes piled high in equally mute tribute to their uselessness in diagnosis!

The ninth case was that of a twenty-five-year-old woman, who had a story, of ten months duration, of an irregular fever of 102 to 103°F, with loss of weight and strength, stomatitis, pain in the flank, pelvis and lower quadrants, and night sweats. She had no cough. On physical examination she was found to have a Grade I apical systolic murmur, a few nodes in the axilla and groin, and tenderness in the right upper and left lower quadrants. Laboratory tests showed a hemoglobin of 57 per cent, a red-cell count of 4,000,000, and a white-cell count of 13,000 to 20,000. Various diagnostic possibilities were considered: tuberculosis, focal infection, and pelvic or renal disease.

By x-ray study she was shown to have a very slightly widened supracardiac shadow, which on fluoroscopy suggested a mass of lymph nodes behind the sternum. X-ray therapy resulted in a decrease in the shadow, and the temperature came down almost by crisis. For the three years since that time the patient has been perfectly well. Apparently the lesion was a localized type of Hodgkin's disease, and the alleviation is probably only temporary. It was stated that very few cases of Hodgkin's disease survive for more than five years, but that one case at the hospital had been followed for ten years. The type that promptly responds to radiation recurs just as rapidly. It was said that this case illustrated the use of x-rays as a method of diagnosis by therapeutic result, it was the sole method of diagnosis and treatment.

The tenth case was that of a sixty-one-year-old man, who had had pain in the chest and dyspnea for six months. The pain was described as pressing on the mid-sternum, usually coming on at night, and lasting several hours. The patient had had no disability on effort. He was admitted with a diagnosis of angina. Physical examination revealed a blood pressure of 128 systolic, 70 diastolic, a normal heart, limited chest expansion, diminished breath sounds, and bronchial squeaks and rales on inspiration and expiration, which were also audible at the front of the chest—findings not consistent with heart failure except in its most terminal stage. There was marked cyanosis. A diagnosis of questionable mediastinal obstruction was made.

Roentgenograms showed moderate enlargement of the mediastinal area, marked pulmonary emphysema and displacement of the trachea, first to the left, then to the right. The diagnosis was a substernal thyroid gland. On fluoroscopy, a typical thyroid plunge could be demonstrated when the patient was asked to cough. The trachea was also displaced forward by the retrotracheal extension of the non-toxic gland.

After operation, breathing was relieved, but as is usually the case, there remained chronic bronchitis and emphysema. Although clinically a mediastinal tumor was suspected, x-ray study more precisely established the diagnosis of thoracic goiter.

For their final case history Dr Levine and Dr Sosman presented an old case, that of a man who was forty-eight years old in 1920 and first came in for angina pectoris. He had pains in the mid-sternum which came on usually in the middle of the night and were unaffected by effort. He had been studied by almost every doctor and clinic in the United States and elsewhere at one time or another, with no success so far as the correct diagnosis or

eatment was concerned. Finally a roentgenogram taken during an attack of pain showed constriction of the ophagus, relieved by a drink of hot water. Esophagoscopy at first suggested carcinoma, then a benign adenoma, but finally a diagnosis of aberrant gastric mucosa and ulcer was made. Thereafter his course was not different from that of the average ulcer patient under treatment, and today he is alive and well at sixty six.

## NOTICES

### SYMPOSIUM ON THE VIRUS AND RICKETTSIAL DISEASES

The Faculty of the Harvard School of Public Health offers a short course of lectures, clinics, and demonstrations on the virus and rickettsial diseases, with special emphasis on their public health significance, to be held at the school during the week of June 12-17.

The fee for the course will be \$25.00, payable at any time up to June 12. Enrollment, however, should be arranged before June 1, as facilities for many of the clinics and demonstrations are limited. The lectures will be published later in a single volume, which will be sent to each person who has registered for the course.

The Registration Office in the Harvard School of Public Health will be open for registration Saturday and Sunday, June 10 and 11, from 9 until 5 o'clock. Persons attending the symposium are requested to register as promptly as possible after arriving in Boston.

Further information may be had by writing to the Secretary of the School of Public Health, 55 Shattuck Street, Boston.

The complete program follows.

#### MORNING SESSIONS

Vanderbilt Hall

MONDAY, JUNE 12

*Presiding*—Dr. Cecil K. Drinker, dean and professor of physiology, Harvard School of Public Health.

10:00-10:10 Greening. President James B. Conant.

10:10-10:45 Epidemiologic Problems in Virus Diseases. Dr. John E. Gordon, professor of preventive medicine and epidemiology.

10:45-11:30 Insects as Vectors of Virus Diseases. Lieut. Col. James S. Simmons, Medical Corps, U. S. Army, assistant corps area surgeon, Headquarters First Corps Area, Boston.

11:30-12:15 The Immunology of Infections by Filterable Virus Agents. Dr. Hans Zinsser, Charles Wilder Professor of Bacteriology and Immunology.

12:15-1:00 The Physical and Chemical Properties of Filterable Viruses. Dr. J. Howard Mueller, associate professor of bacteriology and immunology.

TUESDAY, JUNE 13

*Presiding*—Dr. Edwin H. Place, instructor in communicable diseases, Courses for Graduates and physician-in-chief of the South Department, Boston City Hospital.

9:00-9:30 The Epidemiology and Control of Variola. Dr. Frederick F. Russell, professor of preventive medicine and epidemiology, emeritus.

9:30-10:00 Methods of Preparation and Use of Smallpox Vaccine Virus. Dr. Elliott S. A. Robinson, assistant professor of applied immunology and director of the Division of Biologic Laboratories, Massachusetts Department of Public Health.

10:00-10:15 Generalized Vaccinia. Dr. Ralph A. Ross, assistant in pediatrics.

10:15-10:30 Neurologic Complications of Vaccination. Dr. R. Cannon Eley, associate in pediatrics and communicable diseases.

10:30-10:45 The Etiology of Measles. Dr. John F. Enders, assistant professor of bacteriology and immunology.

#### Recess

11:00-11:40 The Prevention and Modification of Measles. Dr. Charles F. McKhann, associate professor of pediatrics and communicable diseases.

11:40-12:10 Administrative Problems in the Control of Measles. Dr. Harold D. Chope, instructor in public health administration and director of public health, Newton, Massachusetts.

12:10-1:00 Mumps. Its glandular and neurologic manifestations. Dr. Conrad Wesselhoef, associate in communicable diseases.

WEDNESDAY, JUNE 14

*Presiding*—Dr. Frederick F. Russell.

9:00-10:00 The Absorption of Toxic and Infectious Material from the Respiratory Tract. Dr. Cecil K. Drinker.

10:00-10:30 General Considerations of Virus Diseases of the Respiratory Tract. Dr. John A. Mote, associate in research, House of the Good Samaritan, Boston.

10:30-11:00 Distemper in Animals. Lieut. Col. Raymond A. Kelser, Veterinary Corps, U. S. Army, chief of Veterinary Division, Office of the Surgeon General, Washington, District of Columbia.

#### Recess

11:15-12:15 The Human and Swine Influenzas. Dr. John A. Mote.

12:15-12:45 Psittacosis. Dr. John F. Enders.

12:45-1:00 Lymphogranuloma Inguinale. Dr. Nels A. Nelson, lecturer on public health administration and director, Division of Genitoinfectious Diseases, Massachusetts Department of Public Health.

THURSDAY, JUNE 15

*Presiding*—Dr. Richard M. Smith, assistant professor of pediatrics and child hygiene.

9:00-9:30 The Epidemiology of Poliomyelitis. Dr. W. Lloyd Aycock, assistant professor of preventive medicine and hygiene.

9:30-9:50 The Clinical Features and Treatment of Poliomyelitis. Dr. Charles F. McKhann.

9:50-10:10 Poliomyelitis. A review of preventive measures. Dr. W. Lloyd Aycock.

10:10-10:45 The Classification of Encephalitis with a Consideration of Certain Epidemic Types. Dr. LeRoy D. Fothergill, Silas Arnold Houghton Assistant Professor of Bacteriology and Immunology.

## Recess

- 11 00-11 30 The Epidemiology and Prophylaxis of Rabies Lieut. Col. Raymond A. Kelsner  
 11 30-11 55 Equine Encephalomyelitis in Man. Dr LeRoy D Fothergill.  
 11 55-12 25 Lymphocytic Choriomeningitis Dr Kenneth D Blackfan, Thomas Morgan Rotch Professor of Pediatrics  
 12 25-12 40 Louping Ill Dr LeRoy D Fothergill  
 12 40-1 00 Dengue Fever Lieut. Col. James S Simmons

## FRIDAY, JUNE 16

*Presiding*—Dr George C Shattuck, clinical professor of tropical medicine.

- 9 00-9 30 The Etiology of Yellow Fever and the Characteristics of the Infectious Agent. Dr A Watson Sellards, associate professor of comparative pathology and tropical medicine  
 9 30-10 00 The Epidemiology of Yellow Fever Dr Frederick F Russell.  
 10 00-10 30 The Preparation and Use of Yellow Fever Vaccine. Dr John E Gordon  
 10 30-11 00 The Rickettsial Diseases A general survey Dr S Burt Wolbach, Shattuck Professor of Pathological Anatomy

## Recess

- 11 15-11 45 The Diagnosis and Classification of the Rickettsial Diseases Dr Henry Pinkerton, director, Department of Pathology, St. Louis University School of Medicine, formerly, assistant professor of pathology, Harvard University  
 11 45-12 15 The Clinical Features of Rickettsial Diseases Dr John E. Gordon.  
 12 15-1 00 Epidemiology and Immunity in the Rickettsial Diseases Dr Hans Zinsser

## SATURDAY, JUNE 17

*Presiding*—Dr C Sidney Burwell, dean and research professor of clinical medicine, Harvard Medical School

## PANEL DISCUSSION

- 9 00-10 00 Encephalitis Discussion directed by Dr Kenneth D Blackfan  
 10 00-11 00 Rickettsial Diseases Discussion directed by Dr S Burt Wolbach  
 11 00-12 00 Respiratory Diseases Discussion directed by Dr George K. Strode, associate director, International Health Division, Rockefeller Foundation, New York City

## AFTERNOON SESSIONS

## Harvard Medical School and Hospitals

- 2 15-3 15 and 3 30-4 30, daily Demonstration of Absorption from the Nasopharynx. Bldg C<sub>1</sub>, 2nd floor Dr Cecil K. Drinker, Dr Joseph M. Yoffey, research fellow in physiology, and Dr Madeleine F Warren, associate in physiology  
 Demonstration of the Pathologic Lesions of the Virus and Rickettsial Diseases Bldg D<sub>2</sub>, 2nd floor Dr

Henry Pinkerton, Dr Robert N Nye, instructor in bacteriology and immunology, and Dr G Kenneth Mallory, instructor in pathology

Exhibit of Insect Vectors of Virus and Rickettsial Diseases Bldg E<sub>2</sub>, 3d floor Dr Ernest E. Tyzzer, George Fabyan Professor of Comparative Pathology and Dr Joseph C Bequaert, assistant professor of entomology

Demonstration of Bartonella and Other Blood Parasites. Bldg E<sub>2</sub>, 3d floor Dr David Weinman, assistant in comparative pathology and tropical medicine.

Demonstration of Methods of Virus Culture. Bldg D<sub>2</sub>, 3d floor Dr John F Enders and Dr William M Hammon, instructor in epidemiology

3 30-4 30 Encephalitis Clinic. *Children's Hospital* Friday, June 16 If more apply than can be accommodated, there will be an additional clinic on Wednesday, June 14

Poliomyelitis Clinic. *Children's Hospital* Thursday, June 15 If more apply than can be accommodated, there will be an additional clinic on Tuesday, June 13.

Exanthemata Clinic. *Haynes Memorial Hospital* Monday, Tuesday, Wednesday and Thursday, June 12, 13, 14 and 15 Each clinic limited to forty persons Bus service will be provided. If more apply than can be accommodated, an extra clinic will be held on Friday, June 16

In order to avoid overcrowding and confusion, admission to demonstrations and to clinics will be by special ticket only Tickets will be distributed at the time of registration.

The Newton Health Department and the Whittier Street Health Unit, in which the Harvard School of Public Health is interested, will be open for inspection by any of the members of the Symposium who wish to visit them. Arrangement for visits may be made at the Registration Office.

## EVENINGS

## MONDAY, JUNE 12

- 8 30 Reception for Members of the Symposium and Their Families Courtyard and terrace of the Harvard Medical School.

## FRIDAY, JUNE 16

- 8 30 Pops Concert. Symphony Hall, Boston Tickets for the concert may be purchased at the Registration Office.

## ANNOUNCEMENT

AGNES A NERSESIAN, M.D., announces the opening of an office at 153 Nahatan Street, Norwood.

## CARNEY HOSPITAL

The monthly clinical meeting and luncheon of the Carney Hospital will be held in Andrew Carney Assembly Hall on Monday, May 15, at 11 30 a. m. Dr J J Thornton will speak on "Hormone Therapy in Gynecology" Discussion by Drs James J McMan, E. L. Kickham and L. E. Phaneuf will follow

Mr S J Barham of the Associated Hospital Service Cor

poration is going to be present to discuss a very acute problem.

Physicians and medical students are cordially invited to attend.

R. J. HEFFERNAN, M.D., *Secretary*

## BOSTON DOCTORS SYMPHONY ORCHESTRA

Rehearsals of the newly organized Boston Doctors Symphony Orchestra, conducted by Nicolas Slonimsky, are held every Thursday evening at 7 30 at Hampton Court Hotel, 1223 Beacon Street, Brookline.

Membership is still open. All physicians, dentists and medical and dental students who are interested should communicate with Dr Julius Loman, Pelham Hall Hotel, Brookline (BEA 2430)

## BOSTON DISPENSARY

A luncheon meeting of the clinical staff of the Boston Dispensary will be held on Friday, May 19, in the auditorium of the Joseph H. Pratt Diagnostic Hospital, at 12 o'clock noon.

The program, under the auspices of the Department of Nerve and Mental Diseases, will begin at 12 30 p m. Dr Arthur Berk will speak on 'The Newer Methods for the Treatment of Dementia Praecox' and Dr Herbert I Harris will talk on 'A Diagnostic Problem Neurodermatomyositis'.

All those interested in the subject are cordially invited to attend.

ROBERT W. BUCK, M.D., *President*  
JAMES M. BATY, M.D., *Secretary*

## BOSTON LYING-IN HOSPITAL

The Journal Club will hold its next meeting at the Boston Lying-in Hospital on May 17 at 8 15 p m.

### PROGRAM

Diseases of the Veins Dr Edward A. Edwards.  
Experience at the Boston Lying-in Hospital in the Care of Veins During Pregnancy and the Puerperium  
Dr Weston Sewall

Physicians and students are cordially invited to attend.

DUNCAN E. REID, M.D., *Secretary*

## HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held on Tuesday, May 16, in the amphitheater of the Peter Bent Brigham Hospital (Shattuck Street entrance), at 8 15 p m.

### PROGRAM

Presentation of cases.

The Turn of the Century—and After Dr David Cheever

Medical students and physicians are cordially invited to attend.

ROBERT M. ZOLLINGER, M.D., *Secretary*

## MASSACHUSETTS PSYCHIATRIC SOCIETY

The next meeting of the Massachusetts Psychiatric Society will be held at the Metropolitan State Hospital in Waltham, on Friday evening, May 26, at 8 30. Dr Emerick Friedman will speak on 'Alterations in Communicability, Content of Thought and Affective Response During Irritative Therapy'.

W. FRANKLIN WOOD, M.D., *Secretary*

## NEW ENGLAND OBSTETRICAL AND AND GYNECOLOGICAL SOCIETY

The spring meeting of the New England Obstetrical and Gynecological Society will be held at the Maine General Hospital on Wednesday, May 24.

Registration, ward rounds and operative clinics will be held from 8 00 to 12 00 noon. Luncheon will be served at the Maine General Hospital at 1 00 p m., and a meeting of the executive committee will be held at 1 30 p m.

A Dry Clinic at the Nurses Training School on Chadwick Street will take place at 2 00 p m. The program will be as follows:

Congenital Deformity Dr Theodore M. Stevens

Some Interesting Phases of Postpartum Care. Dr Ralph L. Reynolds.

Endometriosis of the Vagina Dr Walter F. W. Hay  
Metastatic Carcinoma of the Ovaries, Three Months Postpartum Dr Carl E. Dunham.

It Has Happened Here. Dr Adam P. Leighton

There will be a general meeting of the society and assembly at Lafayette Hotel at 5 00 p m. Dinner will be served at 6 00. The speaker of the evening will be Dr Martin Sorensen whose subject will be 'The Man from Iceland.'

## NEW ENGLAND PATHOLOGICAL SOCIETY

The annual meeting of the New England Pathological Society will be held at the Evans Memorial Hospital, 72 East Concord Street, Boston, on Thursday, May 18, at 8 00 p m. Dr Ernest W. Goodpasture, professor of pathology, Vanderbilt University School of Medicine, Nashville, Tennessee, will speak on 'Virus and Bacterial Infection in the Chick Embryo.'

Physicians and medical students are cordially invited to attend.

GRANVILLE A. BENNETT, M.D., *Secretary*

## SOCIETY MEETINGS AND CONFERENCES

### CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY, MAY 15

#### MONDAY MAY 15

11:30 a m. Carney Hospital Monthly clinical meeting and luncheon

#### TUESDAY MAY 16

9-10 a m. Roentgenological Diagnosis and Differential Diagnosis of Bone Tumors. Dr Richard Schatzki Joseph H. Pratt Diagnostic Hospital

10 a m. 12:30 p m. Tumor Clinic Boston Dispensary

8 15 p m. Harvard Medical Society Amphitheater of the Peter Bent Brigham Hospital (Shattuck Street entrance)

#### WEDNESDAY MAY 17

9 10 a m. Hospital case presentation Dr S. J. Thannhauser Joseph H. Pratt Diagnostic Hospital.

\*12 m Clinicopathological conference Children's Hospital amphitheater

\*8 15 p m Boston Lying in Hospital Journal Club meeting

#### THURSDAY MAY 18

\*9 10 a m Recent Advances in Electrocardiography Dr H Magen dantz Joseph H Pratt Diagnostic Hospital

\*8 p m New England Pathological Society Evans Memorial Hospital 72 East Concord Street Boston

#### FRIDAY MAY 19

\*9 10 a m Some Clinical Aspects of Heart Disease Dr Reginald Fitz Joseph H Pratt Diagnostic Hospital

\*10 a m 12 36 p m Tumor clinic Boston Dispensary  
12 m Urological conference, Massachusetts General Hospital lower outpatient amphitheater

\*12 m Boston Dispensary luncheon meeting of the Clinical Staff Auditorium of the Joseph H Pratt Diagnostic Hospital

#### SATURDAY MAY 20

9 10 a m Hospital case presentation Dr S J Thannhauser Joseph H Pratt Diagnostic Hospital

\*10 a m 12 m Staff rounds of the Peter Bent Brigham Hospital Conducted by Dr Henry A Christian

## BOOK REVIEWS

*Diseases of the Nose Throat and Ear* W. Wallace Morrison 675 pp Philadelphia and London W. B. Saunders Co., 1938 \$5.50

This latest addition to the several new books on diseases of the ear, nose and throat fulfills in many ways the essential requirements of a good textbook. Adequate attention to anatomy and physiology is combined with clear description of pathological findings. The subjects of history taking and physical examination receive satisfying attention, and treatment is comprehensively covered within the limits of a book dealing with otolaryngology as a whole. Operative procedures are intentionally limited with a view of providing information rather more as to what surgery the patient requires than as to how it should be performed.

The text is illustrated with 350 line drawings all from the author's pen. The labor of such personal illustrating is patently colossal and merits greater success than has, in the reviewer's opinion, been achieved. An attempt to show, in a single drawing, too many individual items has resulted in a multiplicity of numbered designations which is confusing. Such a type of illustration necessitates elaborate legends, the searching of which induces fatigue and even discouragement. Admirable features are a special index of symptoms and a most comprehensive and useful formulary for the medical treatment of many common ailments.

There is a prefaced declaration that the book is intended primarily for undergraduate medical students and general practitioners, that such a book is provided, the reviewer cannot agree. The book on diseases of the ear, nose and throat ideally suited for these readers has yet to be written and cannot be modeled along the classical textbook lines which characterize such books as that of Dr. Morrison.

*Studies from the Rockefeller Institute for Medical Research* Vol 108 and 109 New York The Rockefeller Institute for Medical Research, 1938 \$2.00 each

Volume 108 of the reprints of the Rockefeller Institute for Medical Research contains further reports by Page and others on experimental hypertension. In addition a wide field in chemistry, physical chemistry, pathology, bacteriology, general physiology and animal and plant pathology is covered.

Among the articles of special clinical interest in Volume 109 are studies on aplastic anemia by Rhoads and his associates. Of particular interest, due to the cases of equine encephalitis encountered in New England this fall, is the article by Trager on multiplication of the virus of equine encephalomyelitis in the tissues of the mosquito.

## STRANGULATED HERNIA\*

### A Report of Two Cases in Which the Sac Was Found In An Unusual Location

JOHN E. DUNPHY, M.D.†

BOSTON

WHEN the sac of a strangulated hernia is in an unusual location the difficulties in establishing the diagnosis and the subsequent mortality are greatly increased. Such is the case when strangulation develops in an interparietal hernia. In this condition the sac dissects between the layers of the abdominal wall instead of becoming subcutaneous. This type of hernia is probably more frequent than is generally realized. Many cases are overlooked or are mistaken for abdominal or retroperitoneal tumors. The following case reports are illustrative of the difficulties which may be encountered.

#### CASE REPORTS

*Case 1* A. B., a 57 year-old Jew, entered the Peter Bent Brigham Hospital complaining of abdominal pain, vomiting, distention and obstipation of 24 hours duration. Six years previously the patient had had a course of medical treatment for duodenal ulcer with complete relief of symptoms. Four years before the present admission he had had an attack of severe, cramp-like abdominal pain. The pain was situated in the lower abdomen slightly to the left, and was subsequently associated with nausea, vomiting and abdominal distention. The patient entered another hospital where an x-ray examination of the gastrointestinal tract by means of a barium meal and enema was reported to be negative. A diagnosis of chronic constipation and possible intestinal obstruction of unknown etiology was made. Operation was not thought necessary and the patient was discharged improved. Since that time he had had recurrent bouts of pain, all quite similar in character but less severe than the initial attack. The attack which brought the patient to this hospital was more severe than usual. The pain was accompanied by nausea, vomiting and abdominal distention. Always constipated, the patient felt that this symptom had been more severe in recent months. The last bowel movement was just prior to the onset of the attack.

Physical examination on admission showed a well developed, slightly obese man in moderate distress. The abdomen was moderately distended and tympanitic. In the left lower quadrant there was a tender mass about 10 cm

in length and 6 cm. in width. The external inguinal rings admitted the examining finger, but there was no tenderness, palpable mass or impulse on coughing. Digital examination of the rectum was negative. The temperature was 99°F by rectum, the pulse 90 and the blood pressure 130/80. The white-blood-cell count was 20,600, with 83 per cent polymorphonuclear leukocytes. The red-blood-cell count was 5,000,000, and the examination of the urine was negative.

The diagnosis on admission was intestinal obstruction due to neoplasm of the sigmoid. However, the surgical consultant suggested a diagnosis of a left inguinal hernia which had dissected laterally and upward toward the flank between the internal and external oblique muscles. Further confirmation of this impression was obtained by an x-ray examination which showed evidence of dilated loops of small intestine in a plain film and an apparently normal large bowel by means of a barium enema.

At operation an oblique incision similar to but higher and longer than that usually used for inguinal herniorrhaphy was made. On opening the fibers of the external oblique muscle a tense bluish mass, somewhat irregular in shape, was exposed. This was easily delivered, and proved to be a large hernial sac which had dissected upward and laterally from the internal abdominal ring between the internal and external oblique muscles. The sac contained a strangulated loop of small bowel and omentum. The latter showed extensive necrosis with much old scarring and chronic fat necrosis, indicative of previous attacks of strangulation. As the bowel was viable it was returned to the abdomen. The sac and omental tissue were excised and the neck of the sac closed by high ligation. The inguinal canal was repaired without transplantation of the spermatic cord. The post-operative course was uneventful. There has been no recurrence of symptoms to date, 1 year later.

*Case 2* C. M., a 40-year-old farmer, complained of a chronic pain in the right lower quadrant associated with the appearance of a mass in that area. Some years before, the patient had had an appendectomy with drainage but had never noticed any weakness or bulging in the wound, and the present palpable mass was lateral to the scar of the operation. When first seen, the patient was thought to have a retroperitoneal tumor. He was advised to enter the hospital for diagnostic procedures. This he refused to do. One month later he entered because of increasing pain and vomiting of 48 hours duration.

Physical examination on admission showed an obviously

From the Surgical Service of the Peter Bent Brigham Hospital, Boston.  
†Arthur Tracy Cabot Fellow in Surgery, Harvard Medical School, junior associate in surgery, Peter Bent Brigham Hospital.

ill man in severe pain. The abdomen was distended, tympanic and tender. There was an irregular puckered scar of an incision in the right lower quadrant with the scar of a drainage site about 5 cm. lateral to it. There was a mass 7 cm. lateral to the scar of the drainage site, well away from the incision. It extended from the groin upward and outward toward the right flank. At first it seemed to be retroperitoneal, but the physical examination suggested that the lesion might be more superficial. The clinical picture was obviously that of intestinal obstruction, but the mass could be correlated with this diagnosis only on the assumption that it was a ventral hernia arising from the drainage site and dissecting laterally between the layers of the abdominal wall.

At operation this was found to be the case. Between the internal and external oblique muscles, lateral to the old incision, there was a large hernial sac under acute tension. The neck of the sac could be traced to the site of the old drainage wound. The sac was found to contain a loop of gangrenous small bowel and omentum. Resection of the non viable segment of bowel with end-to-end anastomosis was performed. The convalescence, except for a slight infection in the wound, was not remarkable.

It is interesting that in both these cases the clinical picture was misleading. In one case it suggested a large-bowel lesion, and in the other a retroperitoneal tumor. In fact, these were the diagnoses of several observers. The correct diagnosis was arrived at largely by a proper interpretation of the physical examination, which in both cases suggested that the tumor was in the abdominal wall rather than retroperitoneal or intraperitoneal. A knowledge of the various types of interparietal hernia is a valuable aid in the correct appraisal of the physical examination.

Interparietal hernias are usually of the indirect inguinal type. However, direct or, as in one of the cases reported above, ventral hernias occasionally become interparietal. Interparietal hernias may be divided into three anatomical groups: properitoneal, interstitial and inguinosuperficial.<sup>1</sup> In

the properitoneal type the sac lies between the peritoneum and the transversalis fascia, in the interstitial it lies between the muscles of the abdominal wall, and in the inguinosuperficial it lies between the external oblique aponeurosis and the skin. This latter type is the commonest and is usually quite easily recognized. In the interstitial and properitoneal types the diagnosis is more difficult, and it is in these cases that the hernia is likely to be mistaken for an intraabdominal or retroperitoneal tumor.

Properitoneal and interstitial hernias are often composed of two sacs which are hourglass in shape. One may occupy the usual position in the inguinal canal and the other extend laterally between the layers of the abdominal wall. There is always a common opening into the abdomen at the neck of the sac. The size of the external inguinal ring in these cases may be normal or unusually small.

#### SUMMARY

Two cases of strangulated hernia in which the sac was found in an unusual location (interparietal) are reported. In one of these the sac arose from the internal abdominal ring and passed between the internal and external oblique muscles in a lateral and upward direction. In the other the sac arose at the site of an appendectomy drain and extended laterally into the flank between the same muscles. Familiarity with the various types of interparietal hernia is a valuable aid in the diagnosis and leads to early surgical intervention and a favorable outcome of what otherwise is a highly fatal condition.

## THE FEMALE SEX HORMONES\*

ROBERT T. FRANK, M.D.†

NEW YORK CITY

THE sex cycles of women have been known from time immemorial—the twenty-eight day, menstrual, frustrated or infertile cycle and the two-hundred-and-eighty-day, reproductive or fertile cycle.

Between 1900 and 1915 the anatomical basis of the cycles was studied intensively. Growth maturation of the ovum, ovulation and corpus luteum formation were synchronized with the changes which take place in the uterine mucous membrane. It was determined that during the ovarian follicular phase the mucosa proliferates and during the corpus luteum phase it secretes.

In the succeeding decade, physiological experiments demonstrated that these changes were due to hormones elaborated by the follicle and corpus luteum. Shortly afterward, the primary stimulus of the ovary was discovered to be centered in the anterior pituitary gland. Since then successful efforts have resulted in the production of crude gonadotropic extracts—that is, testicular and ovarian stimulating factors—as well as isolation of pure, crystalline follicular (estradiol) and corpus luteum (progesterone) hormones.

It should be mentioned that the sex hormones, both male androgenic (testosterone), female estrogenic (estradiol), progestational (progesterone) and adrenocortical (adrenosterone), are very similar in structure, that they or some of their derivatives can be changed into each other by chemical means and that they all are closely related to cholesterol. Their generic chemical name is 'steroid' hormones. The importance of this relation is significantly emphasized by the fact that women as well as men excrete both male and female sex hormones. Disturbances in the balance of this normal chemical hermaphroditism may produce serious disturbances.

By means of biological reactions obtained in animals, and in some cases by chemical tests, the presence of these hormones in the blood, urine and tissues has been determined, both qualitatively and quantitatively. This has enabled investigators to demonstrate the underlying hormonal causes which produce the sex cycles (menstrual and reproductive).

In women no cyclical phenomena appear until

the onset of puberty. The menstrual, abortive cycle is initiated by the gonadotropic secretion of the prepituitary, which reaches its acme in the blood stream between the ninth and eleventh days. This hormonal flow stimulates ovarian follicular growth. The growing follicle, in turn, as does the corpus luteum, secretes estradiol, which stimulates the uterine mucosa to proliferate. When ovulation occurs (eleventh to fourteenth day) the corpus luteum secretes estradiol and progesterone. The latter causes secretion of the uterine mucosa, a change essential for successful embedding of the fertilized ovum.

If impregnation is not achieved, the corpus luteum regresses, the secretion of hormones by the ovaries ceases, and bleeding (menstruation) takes place through the degenerating mucosa. If pregnancy should ensue, the corpus luteum persists, and with it a high level of gonadotropic, estrogenic and progestational hormones continues in the blood throughout pregnancy. As a result, the many growth changes in the genital sphere which we associate with pregnancy develop and are maintained.

Hormonal studies performed on hundreds of women have given a welcome and enlightening insight into the hormonal conditions, both in normal states and in functional disease.

Today, however, a complete hormonal study of even one patient has become a formidable task. It entails weekly assay of gonadotropic and estrogenic factors of the blood, and daily assay (in three-day batches) of gonadotropic, estrogenic, corpus luteum and androgenic factors of the urine. The norms for fertile, menstruating women show some variation within well-defined limits. Additional data are obtainable by means of suction biopsies from the uterus and by vaginal smears.

Our investigations have shown that the pituitary-follicular-corpora luteum hormonal mechanism either functions normally or, if disturbed, overfunctions or underfunctions exactly as do other glands of internal secretion.

## OVERFUNCTION

Overfunction is evidenced by a greatly increased excretion of estrogens in the urine but no increase in the blood level, is observed in functional menorrhagia and metrorrhagia. Stationary hyperplasia of uterine mucosa and hyperplasia of the uterine muscle result.

Presented in part at the New England Postgraduate Assembly, Cambridge, Massachusetts, November 16, 1938.

†Clinical professor of gynecology, Columbia University College of Physicians and Surgeons; consulting gynecologist, Mount Sinai Hospital, New York City.

In contradiction to the numerous reported favorable results with gonadotropic factor (Follutein, Antuitrin S or anterior-pituitary-like hormone) I have seen no improvement from the use of these drugs. The results obtained with androgens, recently recommended, have likewise proved disappointing.

The treatment of menorrhagia and metrorrhagia must be varied according to the age group in which it occurs.

In adolescents from eleven to sixteen years old, and young women of sixteen to twenty years, if the basal metabolism is below -15 per cent (often -35 to -25 per cent), thyroid extract in adequate dosage is curative. If the thyroid function is normal, moccasin venom (1:3000) given subcutaneously in doses increasing from 0.2 to 2 cc thrice weekly controls the bleeding.

In mature women, non-endocrine causes of bleeding, such as fibroids, threatened or incomplete abortion, adnexal inflammation, ectopic gestation and cervical and corpus carcinoma, must first be excluded. Ergot, Cotarnine Phthalate and Antuitrin S may be tried but rarely prove effective. Resort should then be had to curettage, the curettings being subjected to microscopic examination. The curettage is of both diagnostic and therapeutic value. Endometrium in the secretory phase signifies that ovulation has occurred. If the curettage has been performed during the third week of the cycle and shows a proliferative phase only, this is interpreted by many clinicians as signifying that the bleeding is due to an anovulatory cycle.

If the patient has reached thirty-five years of age and has completed her childbearing, x-ray therapy may be given to the ovaries at any time within a period of six months following the curettage, should excessive bleeding recur. Preclimacteric bleeding, if severe, demands curettage, and may be followed at once by the intrauterine use of radium or subsequent x-rays to the ovaries.\*

Postmenopausal functional bleeding is due in most cases to a tumor (granulosa cell) of the ovary. Exploratory curettage to exclude carcinoma or polyp and subsequent oophorectomy are indicated. It should be kept in mind that occasional bleeding results from excessive doses of estrogen prescribed for the symptoms of the menopause.

In other words, as is true of the other glands of internal secretion, overfunction in the genital sphere necessitates surgical intervention in most cases.

#### UNDERFUNCTION

In this group I include amenorrhea, functional

sterility and dysmenorrhea. The primary site of the underfunction usually appears to lie in the prepituitary. Two constitutional abnormalities are frequent in this group, namely infantilism and eunuchoidism. The sex cycle is also unfavorably influenced by obesity, malnutrition and pulmonary tuberculosis.

**Amenorrhea** Primary amenorrhea signifies the non-occurrence of menstruation at the expected age (fourteen to seventeen years). Congenital malformations must be excluded. These patients are generally infantile or eunuchoid. Secondary amenorrhea is the cessation of menstruation after the menarche. I have observed the spontaneous return of menstruation after intervals of two to four or even seventeen years.

Bioassay has shown that amenorrheic women may have normal, acyclical or excessive blood and urine cycles. No satisfactory explanation of the non-occurrence of the uterine bleeding can be offered. The amenorrheic uterus does not respond by bleeding to a dose of estrogen which produces bleeding in the human castrate. From five to ten times this dose is required in amenorrhea.

If obesity, malnutrition or markedly reduced thyroid function is noted, dietary measures and thyroid therapy cure the condition. In all other cases my therapeutic efforts have failed. Neither gonadotropic factors or estrogens have helped. In my opinion the results credited to therapy are accidental and coincidental.

**Functional sterility** Many of this group are also amenorrheic. I have observed conception in amenorrheic patients. Others menstruate regularly and appear to possess normal genital organs. I have no data proving that anovulatory menstruation is more frequent in these patients than in normal women.

What has been said concerning the obese and hypothyroid in connection with amenorrhea applies likewise to the functionally sterile. Unless marked stigmas of infantilism or eunuchoidism are manifest, a prognosis is largely guesswork. My predictions have proved wrong so frequently that I no longer venture any. A single ovulation, at times followed by impregnation, has been induced by the intravenous injection of pregnant mare's serum, but I have not attempted this procedure.

**Dysmenorrhea** Menstrual pain is a symptom found in normal, infantile and overworked women. It is not invariably cured by childbirth. The underlying cause is unknown. In mild cases antispasmodics such as atropine (1/250 to 1/100 gr) combined with coal-tar drugs and codeine afford

\*Radiotherapy both with x-rays and with radium should be given solely by fully qualified specialists.

relief Emmenin (sodium pregnandiol glucuronide), an estrogen extracted from the placenta, taken over a period of months, may help. In the severest grades 1 mg of progesterone, the corpus-luteum hormone, injected subcutaneously two or three days before the expected period, and 5 mg with the onset of the pain, relieve but do not cure.

Morphine is contraindicated. I have never performed presacral sympathectomy for this trouble. In several persistent sufferers over thirty-five years of age I have induced the menopause by means of x-ray.

#### PREGNANCY

During pregnancy the hormonal conditions are abruptly elevated to high levels. In the blood the gonadotropic factor increases one thousand times, the estrogenic four times. Exact figures of the change in corpus-luteum hormone are lacking. From these findings it appears illusory to give either gonadotropic extracts or estrogens in pregnancy with any expectation of therapeutic effect. Progesterone may be prescribed in habitual abortion because it does calm uterine contractions and is essential for the embedding of the ovum. It is impossible to gauge the results obtained, particularly as we know that the placenta elaborates

gonadotropic, estrogenic and progestational factors throughout the duration of gestation.

#### MENOPAUSE

The menopause, if physiologic, is manifested by the gradual or abrupt cessation of menstruation. It may have been induced by x-rays or radium, as well as by operative castration. If the uterus alone is removed the blood cycle continues.

In the menopause, cardiovascular symptoms—flushes, sweats, palpitation and dizziness—most commonly develop. Their intensity varies in different individuals. Digestive and arthritic disturbances are frequent. Psychical and mental upsets may occur. Local genital atrophies are the rule. All these manifestations are relieved by adequate doses of estrogens given by hypodermic injection or by mouth. Some patients respond to 5000 international units given three times a week for two weeks. The treatment must be resumed when symptoms recur, if possible with progressively increasing pauses.

Objective guides of the effectiveness of the therapy are disappearance of excess gonadotropic factor in the urine and persistently positive (cornified cells) stained smears from the vagina.

1035 Park Avenue.

## THE PRESENT STATUS OF THE BLOOD SEDIMENTATION RATE

ALLEN S JOHNSON, M.D.\*

SPRINGFIELD, MASSACHUSETTS

**O**BSERVATIONS on the rate of settling of the red blood cells constitute one of the oldest laboratory procedures known to medicine. The writings of Galen in the second century A.D. suggest that the humoral pathologists of his time laid great stress on this phenomenon, albeit their interpretation was erroneous. As humoral pathology fell into disrepute these hematological observations went into the discard until the subject was revived in 1772, by Hewson,<sup>1</sup> who apparently distinguished between the stratification of drawn blood due to coagulation and that due to settling of the erythrocytes. Nasse<sup>2</sup> in 1836 made an exhaustive inquiry into sedimentation velocity and the aggregation of the red blood corpuscles, and the parallelism between the two was later pointed out by Jones<sup>3</sup> in 1843.

The first scientific investigation of this phenomenon began with the epochal studies of Fahraeus<sup>4</sup> in 1917, which resulted from his accidental observations on the increased sedimentation

velocity of the red cells in pregnancy. He recognized that this phenomenon was not specific for any particular disorder or physiological state, and his studies dealt chiefly with the physicochemical factors responsible. Stokes had already determined the velocity of movement of a spherical particle suspended in a fluid of lower specific gravity. Although this law of Stokes applies without modification only when the falling movement of the particle takes place in a fluid of infinite extension, it may be said for practical purposes that the rate of settling of the red cells is proportional to the difference between the specific gravity of the particle and that of the fluid, inversely proportional to the viscosity of the fluid and directly proportional to the square of the radius of the suspended particle. In blood sedimentation this radius is not the radius of the erythrocyte but of the red-cell aggregate, because of the phenomenon of clumping. Fahraeus showed that variations in the difference between the specific gravity of the blood and that of the suspended

\*Assistant Visiting Physician, Springfield Hospital.

particle and in the viscosity of the plasma had little influence on the sedimentation velocity. Of more importance was the red-cell concentration, and of vast consequence was the radius of the suspended particle. Hence the significance of the size of the red-cell aggregates. This size is determined by properties of the blood plasma and appears to be proportional to the serum globulin and serum fibrinogen. Some authors fail to agree with this dictum, such as Aldred-Brown and Munro,<sup>5</sup> who could find no correlation in 54 cases of rheumatic disease between sedimentation rate and fibrinogen percentage or globulin percentage of plasma proteins, and who concluded that the sedimentation rate had no connection with the globulin-albumin ratio, the fibrinogen-globulin ratio or the ratio of fibrinogen plus globulin to albumin and to total proteins. Gilligan and Ernestine,<sup>6</sup> however, demonstrated a close relation between the erythrocyte sedimentation rate and the fibrinogen content of the plasma and concluded that, except in certain cases with liver damage, the plasma fibrinogen plays the major role in controlling the corrected sedimentation index. This theory is likewise accepted by Cutler, Park and Herr,<sup>7</sup> Wintrobe<sup>8</sup> and many others.

The erythrocyte sedimentation rate may be measured by any one of three methods. The Linzenmeyer technic measures the time required for the upper level of the sedimenting cells to fall a given distance. Westergren measures the distance which they fall in a specified period of time. In Cutler's<sup>7</sup> method a graph is constructed from the distance which the sedimenting cells fall per unit of time during an hour. In this way it is possible to demonstrate three phases in the phenomenon of sedimentation: (1) aggregation of the red cells with rouleaux formation, during which little drop in red-cell level occurs and the graph is almost horizontal, (2) the sedimentation phase, during which the graph slopes with varying degrees of abruptness, (3) the packing phase, wherein the rate of sedimentation decreases with a consequent return of the graph toward the horizontal.

Greisheimer, Treloar and Ryan,<sup>9</sup> in a study of the interrelation of these methods, concluded that the average sedimentation in one hour for normal subjects was reasonably concordant for the three methods despite wide differences in tube width, anticoagulant concentration and length of fluid column.

Wintrobe<sup>10</sup> has pointed out certain sources of error in performing the test by whatever method. The rate may be delayed by an excess of anticoagulant. Because cell volume may be materially influenced by the type of anticoagulant used he recommends the combination of ammonium and

potassium oxalate devised by Heller and Paul,<sup>11</sup> in which the shrinking effect of the one salt offsets the swelling effect of the other. This appears to be as reliable as heparin and is certainly much cheaper. The bore and length of the tube must be kept within certain limits and the tube must be maintained in a vertical position if erroneous readings are to be avoided. Temperature likewise influences the rate of sedimentation, but the differences in temperature of the average laboratories will not cause significant error. More than four hours' delay in carrying out the test after withdrawal of the blood may likewise give rise to inaccuracies. For the actual technic of the test the reader is referred to any standard text on laboratory procedures or to the references.<sup>10, 11</sup>

The greatest controversy has raged over the importance of correction for anemia, as it is well recognized that red-cell sedimentation is more rapid in blood having a subnormal concentration of erythrocytes. This is more marked in the short tubes, but Cutler contends that the use of the graph which differentiates the three phases of the phenomenon makes misleading corrections for anemia unnecessary. Wintrobe thinks that such variations in cell volume may interpose significant error in the final reading, and has constructed a logarithmic curve<sup>10</sup> for correction of the sedimentation rate according to the cell volume obtained by high speed centrifugation at the completion of the test. He<sup>8</sup> admits, however, that a correction for anemia may occasionally obscure a pathologic sedimentation rate, and advises that both corrected and uncorrected rates be recorded. Unfortunately, he does not say which one is to be accepted. In spite of this ambiguity I have found the sedimentation test, performed and corrected according to Wintrobe, an exceedingly useful procedure provided its significance and clinical limitations be kept in mind. The uncorrected rate has hardly ever proved to be more accurate when compared with analogous tests and with the clinical picture as a whole. Most investigators agree that the increased length of the Westergren tube (200 mm) obviates the need of correction for anemia or cell volume, as packing here has much less influence on the rate than it does in a shorter tube. Bannick<sup>12</sup> and Bouton<sup>13</sup> have reached substantially these conclusions after particularly careful study. Perhaps the greatest argument in favor of the Wintrobe method is that the subsequent centrifuging makes possible a determination of mean corpuscular volume and icteric index and a rough macroscopic estimation of platelets and leukocytes with a minimum of effort.

The range of normal physiologic variations of any test must be known before it can be relied

on for the detection or measurement of pathologic states. There appears to be a slight difference between the two sexes in the upper limits of normal erythrocyte sedimentation. A correction for this is made only in the Wintrobe method, and recently Wintrobe has advocated abandoning the double standard as unessential. Riseman and Brown<sup>14</sup> found a slight elevation of the rate to be a normal concomitant of old age although Miller<sup>15</sup> considered this insignificant. During pregnancy the sedimentation rate increases from the tenth or twelfth week, and does not become normal until the third or fourth week post partum. The slight fluctuations occurring during menstruation are not important.<sup>8</sup> The taking of food or exercise seems not to influence the sedimentation rate. The most disturbing and apparently the least appreciated cause of variations is due to meteorological conditions. Hoverson and Petersen<sup>16</sup> have shown that just as meteorologic changes can cause variations in leukocytes, fibrin, platelets, corpuscular resistance, and so forth, so they may result in daily variations in the same person's sedimentation rate amounting to 100 per cent.

In spite of these drawbacks the sedimentation test has proved of great value in clinical medicine. Over eleven hundred references in the *Quarterly Cumulative Index* during the last ten years, on which this review is based, attest the general interest in its clinical application. Almost every conceivable clinical entity has been investigated with this procedure, and there is hardly a country not represented in the avalanche of literature which shows no sign of abating. One of the most comprehensive appraisals of its use was based on Cutler's<sup>17</sup> experience with 5000 patients over a six-year period. He emphasized, as had Fahraeus eleven years earlier, that the test was not specific for any particular disease. He pointed out that the mechanism was obscure and that the phenomenon depended on the amount of cellular destruction going on in the body. He listed the diseases giving an abnormal sedimentation rate as follows:

- Chronic infection, such as syphilis or tuberculosis
- Acute infection, such as pneumonia, septicemia or the exanthemas
- Malignancy
- Localized suppuration such as pyosalpinx or mastoiditis
- Acute intoxication such as lead or arsenic poisoning
- Endocrine disturbance, such as thyrotoxicosis

To these we may add, in the light of subsequent investigations

- Acute rheumatic fever
- Acute arthritis, whether rheumatoid, gonorrheal or tuberculous

- Syphilitic aortitis
- Myocardial infarction
- Pertussis (an abnormally low rate)
- Allergy (an abnormally low rate in certain types)
- Liver disease (an abnormally low rate with low plasma fibrinogen)
- Diabetes (r)

Simple catarrhal inflammation, such as uncomplicated appendicitis or a cold, and chronic ulcerations of small extent, such as peptic ulcer, have little influence on the sedimentation rate. The following diseases do not influence the sedimentation rate: functional disorders, as for example of the circulation or gastrointestinal tract, certain nervous disorders like dementia praecox, focal infections, metabolic diseases (diabetes?), allergy (in certain types), skin diseases, simple growths, such as nevi, lipomas and fibromas, simple cysts, and chronic valvular disease of the heart (in the absence of congestive failure).

Most of these conclusions were endorsed three years later by Lesser and Goldberger<sup>18</sup> in a study of three thousand tests on 2000 patients over a two-and-a-half-year period. They found that the normally high rate in pneumonia increased with the onset of complications such as pleurisy or empyema. The sedimentation rate in tuberculosis ran parallel to the activity and extent of the infection. It was elevated in pregnancy and greatly so in the case of a ruptured ectopic pregnancy. They concluded that its greatest value was in the differentiation of acute and chronic salpingitis, as a normal sedimentation rate was practically a guarantee of the absence of an acute pelvic infection. In simple catarrhal appendicitis uncomplicated by abscess or peritonitis the rate was normal in contrast to acute salpingitis, acute cholecystitis and the condition referred to as "the acute surgical abdomen." In rheumatic fever the sedimentation rate was proportional to the degree of activity of the infection. This has been confirmed by Massell and Jones,<sup>19</sup> who concluded that the sedimentation rate and leukocyte count were of about equal value as tests of low-grade rheumatic fever. They believed, however, that the sedimentation rate was the more valuable single test, though it might be increased by upper respiratory infections or tonsillectomy. One wonders if the elevation in these cases with respiratory infections may not have been due to reactivation of the rheumatic infection itself, inasmuch as Gallagher<sup>20</sup> found no elevation of the rate in moderately severe colds in the course of examining several hundred adolescents. Lintz,<sup>21</sup> moreover, encountered no elevation of the sedimentation rate in chronic sinusitis, chronic tonsillitis or periapical dental infections. He concluded that the reduction in sedimentation rate often observed in arthritics after the removal

of one or more of these foci was due to the subsidence of the arthritic process itself

Certain corrections and additions to Cutler's original list seem indicated in the light of subsequent studies. The elevated sedimentation rate in malignancy seems to depend on whether there is tissue destruction as, for example, from necrosis of the neoplasm. Reichel<sup>22</sup> found the rate increased in 90 per cent of cases with malignant tumors, but the evidence is not convincing that mere malignancy can give an elevated rate in the absence of tissue destruction.

Kramer<sup>23</sup> found the sedimentation rate elevated in 67 per cent of 366 diabetic patients. As the elevation could not be correlated with either the duration of the disease or the level of the blood sugar, he concluded that it was due to some focal infection, though this hardly appears warranted in view of the work of Lintz.<sup>21</sup>

Not only in rheumatic fever is the sedimentation rate increased but also in rheumatoid, tuberculous and gonorrheal arthritis.<sup>8</sup> In these conditions, likewise, it appears to be a valuable guide to the severity and progress of the disorder.

Danzer<sup>24</sup> has pointed out that the rate is elevated in syphilitic aortitis. This has been confirmed by Wood,<sup>25</sup> who found it elevated also in myocardial infarction but retarded in congestive heart failure. As aortic dilatation due to hypertension or arteriosclerosis is not attended by an elevated sedimentation rate, this test may prove of considerable value in establishing a syphilitic etiology in the face of the negative blood Wassermann test occasionally reported in cases of syphilitic aortitis. Riseman and Brown<sup>14</sup> have confirmed Wood's findings in myocardial infarction and has also observed an elevated sedimentation rate in many cases of angina pectoris. Although the figure in these cases is lower than it is in coronary thrombosis, one questions the reliability of the test in differentiating the two conditions. Certainly the writer has been repeatedly confronted with corrected sedimentation rates several times the upper limit of normal in patients whose clinical history, temperature and serial electrocardiograms only warranted a diagnosis of angina pectoris. This phenomenon may be due to minute areas of myocardial softening in the region of the coronary spasm which are too slight to produce the other clinical and laboratory evidence demanded for a diagnosis of myocardial infarction. In true myocardial infarction, however, an elevated sedimentation rate is so constant a finding, as these investigators, as well as Shookhoff, Douglas and Rabinowitz<sup>26, 27</sup> have shown, that one must agree with Riseman that a persistently normal or only slightly increased sedimentation rate between the fourth and

the twelfth day after an attack of substernal pain is strong evidence against infarction.

Another use of the sedimentation rate not originally recognized by Cutler may lie in the diagnosis of whooping cough. Gold and Bell<sup>28</sup> believe that the triad of cough, leukocytosis with relative lymphocytosis and a normal or subnormal sedimentation rate is pathognomonic of pertussis, and have found a low rate in 94 per cent of the cases which have reached the stage of coughing.

Contrary to Cutler's original conclusions, allergy may affect the sedimentation rate. Schulhof<sup>29</sup> states that unless the rate is masked by infection it is abnormally slow in allergic patients and in their non-allergic close relatives. Another cause of a decreased rate is liver disease which results in a diminished plasma fibrinogen.<sup>8</sup>

Linton<sup>30</sup> believed at one time that the sedimentation was rapid in patients with obstructive jaundice who had a postoperative tendency to bleed, whereas it was normal or slow in those with no such hemorrhagic tendency. Clute and Veal's<sup>31</sup> studies have led them to question the reliability of this test, and Burke and Weir<sup>32</sup> state that the sedimentation rate is of no value in predicting postoperative hemorrhage in jaundice.

It is evident that we have learned little more of the fundamental mechanism of erythrocyte sedimentation since the epochal work of Fahraeus twenty years ago, in spite of literally thousands of papers on the subject. That it is not specific for any particular disease is well established. That the underlying mechanism is obscure is apparent. That it depends on, and is commensurate with, tissue destruction, however, is well agreed. The technical pitfalls are many, the intrinsic and extrinsic factors capable of distorting the sedimentation rate are insidious. Yet the very appreciation of its shortcomings and limitations makes this oldest of laboratory tests an extremely valuable tool to the clinician.

## REPORT ON MEDICAL PROGRESS

### ELECTROLYTE AND WATER BALANCE\*

ALLAN M. BUTLER, M.D.†

BOSTON

THE clinician without access to a modern clinical laboratory need not necessarily feel that he is unable to take advantage of many of the chemical advances made in the treatment of disease. Although accurate chemical methods have of necessity been employed in the unraveling of certain clinical problems, the knowledge so acquired not infrequently enables the experienced physician to estimate metabolic disturbances by accurate clinical observations, and thus to reduce his dependence on information provided by the more elaborate laboratory procedures. On the other hand, there are many types of disease in which accuracy of diagnosis still depends to a large extent on chemical analyses.

It is the purpose of the present review to point out some of the frequently encountered disturbances in salt and water balances in which diagnosis and therapy are based on chemical analyses or reasoning.

The expositions of Gamble,<sup>1</sup> Peters<sup>2,3</sup> and Peters and Van Slyke<sup>4</sup> have clarified our understanding of the disturbances in salt and water balances associated with pathologic conditions that are frequently of concern to clinicians. It is now clear that edema and dehydration are more closely related to the masses of body fluids than to their

composition, whereas acidosis and alkalosis are dependent on the relative concentration of certain cations and anions of the body fluids. Since clinically significant dehydration and acidosis or alkalosis are often associated conditions, diagnosis and therapy require attention to the amount and composition both of the body fluids and of the repair solutions administered therapeutically.

A few years ago clinical analyses of the ionic composition of a patient's blood serum were often reported in such a variety of units that the physiological significance of abnormal concentrations was difficult to visualize. For example, in analyzing a patient's serum, total cations might have been reported as 140 cc. of N/10 base per 100 cc., chlorides as 320 mg per 100 cc., and carbon-dioxide content as 40 vol per cent. The correlation of values, expressed in such different units, to obtain a picture of the physiologic disturbance could not be made. Indeed, some laboratories might have reported the above serum-chloride analysis as 527 mg of sodium chloride per 100 cc., thus converting a perfectly good analysis into a misleading or meaningless result. Now, however, the expression of all plasma electrolyte concentrations in terms of milliequivalents per liter permits a ready comparison of changes which have occurred in different constituents. The normal values for the plasma electrolytes in this nomenclature are

From the Department of Pediatrics, Harvard Medical School and the Infants and the Children's hospitals, Boston.

†Assistant professor of pediatrics, Harvard Medical School; assistant visiting physician, Infants and Children's hospitals, Boston.

CATIONS		ANIONS	
	<i>m.eq</i>		<i>m.eq</i>
Sodium	138	Bicarbonate	26
Potassium	5	Chloride	104
Calcium	5	Proteinate	17
Magnesium	2	Sulfate	1
		Phosphate	2
Totals	150		150

As an illustration of the increase in information gained by employing these recognized clinical units, we may refer again to the serum of the patient cited above. Expressed as milliequivalents per liter the total cations=140, and of the anions, chloride=90 and bicarbonate=18. If the other anions normally present, that is proteinate, sulfate and phosphate, amount to their usual value of 20 milliequivalents, one has still only accounted for 128 of the 140 anion units which we know must be present for electrical neutrality. Clearly, then, the concentration of one or more of the anions normally present has increased or some abnormal anion is present in the plasma. Clinical observation, physiological reasoning and chemical analyses, singly or together, may be used to supply more specific information. But whether or not further analyses are made, the expression of such serum analyses in a single unit of concentration clarifies the clinical significance of the data. Gamble's<sup>5</sup> exposition of the chemical anatomy, physiology, and pathology of extracellular fluid clearly demonstrates the manner in which this unit of concentration permits a simple graphic representation of the chemical patterns of the blood plasma in pathologic conditions, which are otherwise difficult to visualize.

#### DEHYDRATION

No new single laboratory procedure has been introduced which indicates the presence and degree of dehydration better than the classical physical signs of dry tongue and mucous membranes, lack of skin turgor, sunken and soft eyeballs and, in the infant, depression of the fontanelle. Occasionally, however, dehydration associated with obesity or peripheral edema may be difficult to appraise without the aid of laboratory determinations. Those commonly used to obtain confirmatory or quantitative data are

- 1 Plasma volume<sup>6</sup> 7
- 2 Specific gravity of serum<sup>8</sup> 9 10 or concentration of serum proteins (refractometric,<sup>11</sup> Kjeldahl<sup>12</sup>)
- 3 Red blood-cell count
- 4 Hematocrit
- 5 Hemoglobin
- 6 Blood nonprotein nitrogen or urea nitrogen<sup>12</sup>

These procedures have both practical and theoretical limitations. Determination of the plasma

volume, if done accurately enough to be reliable, is too time-consuming for general clinical use. The same criticism applies to the determination of the extracellular fluid volume by the sodium thiocyanate method.<sup>13</sup> The last four procedures may provide evidence of dehydration, if values above the norms are obtained. But many of the patients for whom estimation of the degree of dehydration is desired suffer from other disturbances which affect the values obtained by these determinations. Starvation or Bright's disease may have lowered the serum proteins so that a normal serum specific gravity or protein concentration may be obtained in the presence of dehydration. Multiple myeloma, kala-azar or a liver tumor may give elevated values for serum specific gravity and protein concentration although dehydration is not present. A lipemia or azotemia may cause a high refractometric reading which is not the result of a high serum protein and dehydration. The red-blood-cell count, hemoglobin concentration and hematocrit reading are affected by anemia or polycythemia as well as by dehydration. The nonprotein nitrogen or urea nitrogen may be elevated because of renal insufficiency as well as by the oliguria of dehydration. Or the diabetic patient who is excreting a large volume of urine may be dehydrated without appreciable retention of nitrogen.<sup>14</sup>

Low serum sodium and chloride concentrations may be associated with the loss of fluids by vomiting, diarrhea and ileostomy or cecostomy drainage.<sup>15</sup> 16 They are also frequently observed in diabetic coma,<sup>14</sup> 17 18 severe chronic nephritis<sup>19-21</sup> and Addison's disease.<sup>24</sup> 25 Though they are related to the dehydration frequently present, they are not a measure of it. However, in such cases the determination of the serum concentrations of these substances may be very helpful in explaining symptoms and guiding therapy.

#### CONTROL OF HYDRATION THERAPY

More important clinically than the estimation of the degree of dehydration by laboratory determinations is the accurate control of parenteral hydration therapy by data obtained from chemical analyses.<sup>13</sup> 23 26 Since in dehydration the diminished blood volume and blood flow through the kidneys usually result in oliguria and poor renal function, plasma concentration changes are prone to occur prior to an improvement in renal function which is adequate enough to defend normal plasma concentrations. Because parenteral fluid is usually required when starvation has diminished the body nitrogen and when body fluid loss has reduced the body sodium and chloride, the administration of fluids which do

not provide sodium and chloride and plasma proteins or their nitrogenous precursors may result in a marked drop in the concentrations of these constituents of the plasma. Thus, the administration of glucose solution alone to the dehydrated patient may lower the plasma sodium and chloride concentrations to values of 115 and 60 miliequivalents per liter, respectively. Such changes so disturb the osmotic equilibrium between extracellular fluid and intracellular fluid that loss of electrolytes from the cells or passage of water into the cells produces a marked lowering in cellular concentrations.<sup>27-29</sup> The administration of isotonic sodium chloride solution may so lower the plasma protein concentration that edema results.<sup>23, 30</sup> If pulmonary edema occurs, the effect of the therapy may be unfortunate. Or, as discussed below under the next heading, the administration of sodium chloride solution alone may produce an increase in the plasma chloride concentration and a decrease in plasma bicarbonate sufficient to produce or accentuate an acidosis. The administration of parenteral fluids may be accompanied by such a fall in plasma protein concentration that edema develops before the blood volume is restored, or by such a drop in red-cell count and hemoglobin that an anemia previously masked by the dehydration becomes apparent. In either case transfusion becomes an essential part of the hydration therapy.<sup>31</sup> Clearly, then, continuous parenteral therapy for periods of twenty-four hours or longer demands a knowledge of its effects on the concentrations of plasma proteins, sodium and chloride. With a properly equipped laboratory at hand, all three of these concentrations can be determined on a 1- to 2-cc sample of serum.<sup>10-12, 32-34</sup> Without a laboratory at hand to guide parenteral fluid therapy, the factors described above demand due consideration.

With dehydration and starvation there occurs with the loss of extracellular water and constituents a loss of intracellular substances. This loss is not replaced by present-day parenteral fluid therapy. Therefore an essential part of repair therapy is the oral administration of food as soon as this may be given without danger of a recurrence of any gastrointestinal disturbance that may have existed. It is as yet too early to discuss the administration of amino acids parenterally. Though nitrogen balances have been maintained by such therapy, severe reactions have been encountered.<sup>35-37</sup>

#### ACIDOSIS AND ALKALOSIS

##### Diagnosis

The types of alkalosis and acidosis most frequently encountered in clinical medicine are those designated as "metabolic acidosis and metabolic

alkalosis."<sup>38, 39</sup> These are the types in which hyperventilation and a low serum carbon-dioxide content accompany acidosis and in which hypopnea or Cheyne-Stokes respiration and a high serum carbon-dioxide content accompany alkalosis. Thus both the character of the respirations and a single chemical analysis indicate, in what might be termed the orthodox fashion, the nature of the disturbance. However, the diagnosis of acidosis and alkalosis cannot always be reduced to such simple indices as respiratory effort and serum carbon-dioxide content.\* The respiratory center may be depressed or may be stimulated abnormally, so that the type of respiration does not reflect the disturbances in acid-base equilibrium, and a decrease or increase in serum carbon-dioxide content no longer indicates respectively acidosis or alkalosis. The Henderson-Hasselbalch equation shows clearly the relation between the variables which the clinician must consider, if he is successfully to diagnose and treat the puzzling cases. The equation states,

$$\text{pH} = 6.10 + \log \frac{\text{HCO}_3}{\text{H}_2\text{CO}_3}$$

In normal serum,  $\text{pH}=7.4$ , the carbon dioxide from  $\text{HCO}_3=26$  millimols per liter, and the carbon dioxide from  $\text{H}_2\text{CO}_3=1.3$  millimols per liter. Keeping in mind that the concentration of  $\text{H}_2\text{CO}_3$  in the plasma is determined by the concentration of alveolar carbon dioxide and that this latter concentration is dependent on pulmonary ventilation, it is seen that the equation provides the clinician with the essential relation between pulmonary ventilation, bicarbonate content of the plasma and plasma pH. The pH is not dependent on the total carbon-dioxide content of the plasma, which can be measured readily, but on the ratio of  $\text{HCO}_3/\text{H}_2\text{CO}_3$ , of which neither the numerator nor the denominator is easily measured. This leads to the difficulties which bother the clinician.

Changes in the ratio,  $\text{HCO}_3/\text{H}_2\text{CO}_3$ , can usually be inferred from the total serum carbon-dioxide content, the history and type of respirations. When inference of this kind is possible, the determination of the serum carbon-dioxide content permits a satisfactory estimation of the three variables in the equation. However, the puzzling aspects of many cases cannot be resolved so simply. In such cases the colorimetric determination of the serum pH<sup>39</sup> in addition to the gasometric determination of total carbon-dioxide content of the serum, shows whether alkalosis or

\* For the ordinary clinical laboratory the determination of the carbon dioxide content seems preferable to the determination of the carbon dioxide combining power of the plasma.<sup>32</sup>

acidosis is present and, if desired, permits the estimation of the  $\text{HCO}_3$  and  $\text{H}_2\text{CO}_3$  concentrations. For, from the original equation, since  $\text{HCO}_3 = \text{total CO}_2 - \text{H}_2\text{CO}_3$ ,

$$\text{H}_2\text{CO}_3 = \frac{\text{total CO}_2}{1 + \text{antilog (pH} - 6.1)}$$

Shock and Hastings<sup>40</sup> have recently introduced a method of doing both determinations on 0.1 cc. of capillary blood.

From the Henderson-Hasselbalch equation it is clear that a low total carbon-dioxide content of serum, that is the carbon dioxide from both the  $\text{HCO}_3$  and the  $\text{H}_2\text{CO}_3$ , indicates a low pH and acidosis only if the ratio,  $\text{HCO}_3/\text{H}_2\text{CO}_3$ , is less than normal. Such a lowering of both total carbon dioxide and the ratio occurs where the primary change is a reduction of the  $\text{HCO}_3$  either by loss of sodium or by accumulation of anions other than  $\text{HCO}_3$  in the blood or by both. This is by far the commonest type of acidosis and has been termed *metabolic acidosis*. It occurs in diabetic acidosis, the acidosis of severe renal insufficiency and the acidoses which accompany severe exercise, the ingestion of acids or acidifying salts and dehydration due to loss of gastrointestinal secretions and to the ensuing oliguria.

From the equation it is also clear that a low total carbon-dioxide content of serum may be associated with an increase in the  $\text{HCO}_3/\text{H}_2\text{CO}_3$  ratio above normal and therefore with an increase in pH and alkalosis. This situation occurs where the primary change is a decrease in alveolar carbon-dioxide pressure which causes a decrease in carbon dioxide dissolved in the plasma and a decreased carbonic acid ( $\text{H}_2\text{CO}_3$ ) concentration. This has been called the alkalosis of primary carbonic-acid deficit<sup>4</sup> or more simply, *respiratory alkalosis*.<sup>38</sup> It may be the result of the hyperpnea of encephalitis,<sup>41</sup> hysteria,<sup>42</sup> certain respiratory stimulants and oxygen lack.<sup>43</sup>

Again referring to the equation, a high serum carbon-dioxide content may be associated with an increase in the ratio and alkalosis. This has been called *metabolic alkalosis*, and may occur with the ingestion of alkaline salts, particularly in the presence of renal insufficiency<sup>44</sup> or with the loss of chloride in excess of sodium as frequently results in gastric vomiting.<sup>45</sup>

Or a high serum carbon-dioxide content may be associated with a decrease in the ratio and an acidosis. In this case the acidosis is one of primary carbon-dioxide excess<sup>4</sup> or a *respiratory acidosis*.<sup>38</sup> It may occur where there is suppression of the activity of the respiratory center because of toxins or exhaustion, paralysis of the respiratory muscles, upper respiratory obstruction or emphysema.

An accurate diagnosis of the type of alkalosis or acidosis is a prerequisite to the best therapy. The dependence of the clinician on laboratory analyses will vary with individual circumstances.

For example, in a case of diabetic coma, where the history is typical, the physical signs of dehydration, ketosis and hyperpnea are classical, and the glucosuria, ketonuria and hyperglycemia confirm the diagnosis, the chemical changes in the blood conform so closely to the pattern established by previous studies<sup>14, 17, 18, 46</sup> that the quantitative determination of the degree of acidosis contributes little diagnostically or therapeutically unless complications arise.

On the other hand, in a dehydrated patient with a history of diarrhea and vomiting, where the respiratory response may be depressed by toxemia and the urinary findings will be of almost no assistance,<sup>47</sup> the differential diagnosis of metabolic acidosis and metabolic alkalosis may depend on the determination of the carbon-dioxide content of the serum. Not infrequently a desirable understanding of the extent of specific concentration changes in the plasma occasioned by the loss of fluids is obtained only after determining the serum sodium and chloride concentrations as well.

In the treatment of a nephritic patient with acidosis it is important to know whether the lowered serum carbon-dioxide content is due to a diminished serum sodium or to an increase in the concentration of serum anions caused by the retention of metabolites. And the recognition of the recently described syndrome of chloride acidosis and nephrocalcinosis<sup>48, 49</sup> depends largely on the detection of a lowered serum carbon-dioxide and an elevated serum chloride concentration.

The diagnosis of respiratory alkalosis or acidosis usually depends on the determination of plasma pH and carbon-dioxide content. The determination of serum sodium and chloride concentrations may be helpful.

Finally, there are cases where combinations of conditions make appraisal of the situation extremely difficult. A case of methyl salicylate poisoning,<sup>50, 51</sup> for example, may be very puzzling. The vomiting tends to reduce the plasma chloride and to produce a high serum carbon-dioxide content and alkalosis. The salicylate, as a foreign organic anion, may tend to lower the serum carbon dioxide and produce an acidosis. The drug may stimulate the respiratory center, producing a hyperpnea with a low serum carbon dioxide and respiratory alkalosis. A correct appraisal of the situation, in order to ascertain whether sodium lactate or bicarbonate is indicated or definitely contraindicated by the hyperpnea, may require careful integration of the history and physical findings and several chemical determinations.

Shock and Hastings<sup>39</sup> have pointed out that the application of microtechnics in determining the acid-base equilibrium of the blood permits studying the paths of acid-base displacement and recovery after experimental displacement. Their use of triaxial co-ordinates is particularly appropriate for the graphic presentation of the three variables of the Henderson-Hasselbalch equation. Moreover, by plotting the logarithm of the percentage change in bicarbonate against time they obtained a linear relation in which the slope, "K," characterized the rate at which the blood returned from the experimental displacement to normal. Because the re-establishment of equilibrium depends largely on renal function their "constant of elimination" should prove useful in the evaluation of renal disease.

### Therapy

Clinically, *respiratory acidosis* is not in itself serious. In many cases the increase in plasma carbonic acid is beneficial because it stimulates respiration. Treatment, therefore, is directed not toward the acidosis but toward the cause underlying the respiratory disturbance.

*Respiratory alkalosis* only infrequently leads to symptoms of tetany which require treatment per se. If the tetany does demand immediate specific treatment, air containing an increased amount of carbon dioxide may be administered by having the patient rebreathe from a bag or from a closed oxygen tent with the soda lime removed from the system, or by supplying carbon dioxide directly to the inspired air. Morphine may also be helpful. The administration of calcium or ammonium chloride by mouth may increase the compensatory elevation of plasma chloride. Permanent relief, however, depends on treatment of the underlying disturbance. To mistake this type of alkalosis for acidosis and to administer an alkaline sodium salt may lead to serious tetany.

Adequate treatment of *metabolic alkalosis* resulting from an intake of alkaline sodium or potassium salts which exceeds the kidney's excretory ability is usually accomplished by discontinuing the alkaline salt and administering such amount of fluid as will provide a large volume of urine.

*Metabolic alkalosis* caused by the loss of gastric hydrochloric acid usually occurs in patients whose vomiting prevents the oral ingestion of food, fluid or medication. Dehydration and some degree of starvation therefore accompany the alkalosis and also demand treatment. Parenteral physiological saline solution is ideal for correcting the alkalosis and dehydration. It provides the three essential

substances, water, sodium and chloride, and in supplying the two latter in equal amounts\* tends to increase the plasma chloride concentration and to diminish the alkaline reserve.<sup>52</sup> The intravenous infusion of 10 per cent glucose solution stimulates the circulation, treats the starvation and provides fluid for an adequate volume of urine.

*Metabolic acidosis* due to sodium deficit sustained through loss of body fluid is usually accompanied by a gastrointestinal condition that prevents either the ingestion or absorption of substances taken orally. Dehydration and starvation are almost always present and demand treatment. The therapy must usually be provided by intravenous infusions and clyses or by continuous intravenous drip.

The dehydration and acidosis are treated by the parenteral administration of fluid containing chloride and sodium in concentrations appropriate to repair the plasma and extracellular fluid deficits and to correct the acidosis by providing for an increase in the diminished alkaline reserve. In the presence of the diminished renal function it is clear that physiological saline solution\* is not an appropriate solution for the initial parenteral therapy. In the dehydrated oliguric patient physiological saline solution tends to raise the serum chloride, lower the alkaline reserve and lower the pH of the blood.<sup>15, 28</sup> The introduction of sodium *r*-lactate for parenteral therapy by Hartmann and Senn<sup>53, 54</sup> provides a convenient, economical and appropriate parenteral solution. One part of M/6 sodium *r*-lactate solution to two parts of physiological saline solution makes a solution which contains approximately 150 milliequivalents of sodium and 100 milliequivalents of chloride per liter. The administration of this solution to the dehydrated acidotic patient provides the means of repairing the dehydration and restoring the alkaline reserve. If the acidosis is extreme, equal parts of the two solutions may be used in the initial stages of therapy. The total amount of solution to be administered is determined by the amount required to correct the dehydration. The rate of administration is based on the amount that can be given safely to each individual patient per unit of time. The therapy is controlled as already discussed under the section on the control of hydration therapy. The specification of a given number of cubic centimeters of M/6 sodium lactate solution and physiological saline solution per kilogram of body weight<sup>55</sup> seems too rigid and dogmatic to be recommended. The administration of

\*The concentrations of chloride and sodium in physiological saline solutions are each approximately 155 milliequivalents per liter. Hence the chloride concentration exceeds the normal plasma chloride concentration by 50 milliequivalents per liter.

that amount of sodium which by calculation<sup>64 66</sup> should bring the alkaline reserve, as measured by the serum carbon-dioxide content, back to normal seems theoretically of doubtful validity and practically an unphysiological procedure. There seems little justification to the use of solutions which substitute expensive Ringer's solutions for physiological saline solution. If calcium is needed, its specific administration in therapeutically effective amounts seems preferable to relying on the calcium supplied in Ringer's solution. There is no evidence to support the parenteral administration of potassium.

Except in cases of diabetic coma where intravenous glucose is not helpful and may be harmful,<sup>67</sup> the starvation is treated by 10 per cent glucose given intravenously. If the starvation is a prominent part of the picture, the basic caloric needs can be met by glucose supplied by a continuous intravenous drip without entailing hyperglycemia and glycosuria.

Metabolic acidosis due to retention of anions occurs as the result of renal insufficiency, faulty metabolism or the administration of salts which demand the differential excretion of so-called "fixed base." The last type of retention is usually corrected when the administration of the salt is discontinued. Diabetes mellitus and starvation both result in the retention of the ketone acids. The use of glucose in the treatment of the ketonemia of starvation has already been mentioned. The ketonemia in diabetes mellitus is treated by the administration of insulin while the dehydration and acidosis due to sodium deficit are being treated as outlined above. The retention of anions due to renal disease is frequently associated with diminished plasma sodium and chloride concentrations.<sup>19-23</sup> Treatment consists in providing a diet that demands a minimal excretion of the retained catabolic products, an adequate caloric intake, a liberal sodium and chloride intake (the former being somewhat in excess of the latter) and a large volume of urine.<sup>19 58 59</sup>

The recent work of Guest and Rapoport<sup>60 61</sup> on the role of diphosphoglyceric acid in the acid-base equilibrium of the blood cells has important therapeutic implications. Phosphate appears to be an essential factor in the restoration of the cells' normal chemical structure. If effective methods of providing phosphate can be found, the treatment of acidosis may be extended beyond the confines of the inactive plasma and extracellular fluids and into the regions of active cellular metabolism.

#### ADDISON'S DISEASE

Loeb<sup>24</sup> and Loeb, Atchley and Parson<sup>26</sup> have

called attention to and carefully analyzed the abnormal pattern of the blood serum in Addison's disease. The abnormalities commonly found are a decrease in serum sodium and glucose concentrations and an increase in the concentrations of serum potassium and nonprotein nitrogen.

The marked increase in the urinary excretion of sodium and chloride in Addisonian crises and the restoration of normal excretion by use of cortical extracts have been described by several groups of workers.<sup>62 64</sup>

The beneficial effects of the ingestion of sodium chloride in such amounts as will maintain normal plasma concentrations and salt balance have been demonstrated by Loeb and his co-workers,<sup>65 66</sup> Harrop, Soffer, Nicholson and Strauss,<sup>67</sup> and others. The desirability of a restricted potassium intake as recommended by Wilder, Snell, Kepler, Rynearson, Adams and Kendall<sup>68</sup> has not been confirmed by general experience.

Loeb, Atchley, and Parson<sup>25</sup> concluded that a decrease in serum sodium concentration was the most sensitive chemical criterion of adrenal insufficiency in man. Harrop and his co-workers<sup>63</sup> have suggested the use of a salt-free diet as a diagnostic test. During the period of salt restriction, which is usually from three to five days, the patient is observed for symptoms of an Addisonian crisis, for a decrease in plasma sodium and chloride and for a high urinary chloride excretion. Because the test may provoke a serious crisis, they call attention to the necessity of the closest medical supervision. Zwemer and Truszkowski<sup>69</sup> suggested the diagnostic procedure of feeding 10 to 20 mg of potassium per pound of body weight and determining the concentration of potassium in the serum at frequent intervals. Wilder and co-workers<sup>68</sup> suggested the ingestion of potassium as a means of provoking an increased excretion of sodium and potassium.

However, chemical studies to determine serum concentrations and urinary excretions under the controlled conditions mentioned above provide confirmatory, not specific, evidence for the diagnosis of Addison's disease, and entail appreciable risk to the patient. The changes in the chemical composition of serum and the negative sodium and chloride balances which occur in Addison's disease are frequently observed in nephritis,<sup>10-13</sup> asthenia,<sup>70</sup> dehydration<sup>15 16 71</sup> and uncontrolled diabetes.<sup>14 17 18</sup> The ingestion of potassium salts by the nephritic patient may be associated not only with an increase in plasma potassium and urinary sodium excretion but also with serious untoward symptoms.<sup>72-76</sup>

More recently Cutler, Power, and Wilder<sup>77</sup> have described a simplified procedure for the diagnosis of Addison's disease. The test involves the administration of standard amounts of water and potassium and sodium chloride for two days and the determination of the concentration of sodium or chloride in the urine the morning of the third day. Because the analysis of chloride in urine is easier than that of sodium, chloride alone usually is determined. Urinary concentrations of chloride greater than 63 milliequivalents per liter are stated to indicate adrenocortical deficiency. The specificity of this test still needs verification by demonstrating its ability to distinguish Addisonian patients from those with the conditions mentioned above who tend to excrete large amounts of sodium and chloride in the urine, even in the presence of low sodium and chloride concentrations.

Moreover, the repeated observation of Addisonian crises with hemoconcentration and diminished plasma volume, without a decrease in the serum sodium concentration and without a loss of body sodium, chloride or water by way of the urine, suggests the important role that abnormal distribution of water and electrolytes may play in this disease.<sup>23 78-80</sup> Data are not yet available which are adequate to show that the determination of the total plasma sodium (as measured by the plasma volume and sodium concentration) is a more satisfactory criterion of Addison's disease than are serum concentration and urinary excretion values.

The recent work of Thorn, Engel and Eisenberg<sup>81</sup> with desoxy-corticosterone gives promise that this synthetic product will provide more economical and effective therapy than any now available.

that amount of sodium which by calculation<sup>54 56</sup> should bring the alkaline reserve, as measured by the serum carbon-dioxide content, back to normal seems theoretically of doubtful validity and practically an unphysiological procedure. There seems little justification to the use of solutions which substitute expensive Ringer's solutions for physiological saline solution. If calcium is needed, its specific administration in therapeutically effective amounts seems preferable to relying on the calcium supplied in Ringer's solution. There is no evidence to support the parenteral administration of potassium.

Except in cases of diabetic coma where intravenous glucose is not helpful and may be harmful,<sup>57</sup> the starvation is treated by 10 per cent glucose given intravenously. If the starvation is a prominent part of the picture, the basic caloric needs can be met by glucose supplied by a continuous intravenous drip without entailing hyperglycemia and glycosuria.

Metabolic acidosis due to retention of anions occurs as the result of renal insufficiency, faulty metabolism or the administration of salts which demand the differential excretion of so-called "fixed base." The last type of retention is usually corrected when the administration of the salt is discontinued. Diabetes mellitus and starvation both result in the retention of the ketone acids. The use of glucose in the treatment of the ketonemia of starvation has already been mentioned. The ketonemia in diabetes mellitus is treated by the administration of insulin while the dehydration and acidosis due to sodium deficit are being treated as outlined above. The retention of anions due to renal disease is frequently associated with diminished plasma sodium and chloride concentrations.<sup>19-23</sup> Treatment consists in providing a diet that demands a minimal excretion of the retained catabolic products, an adequate caloric intake, a liberal sodium and chloride intake (the former being somewhat in excess of the latter) and a large volume of urine.<sup>19 58 59</sup>

The recent work of Guest and Rapoport<sup>60 61</sup> on the role of diphosphoglyceric acid in the acid-base equilibrium of the blood cells has important therapeutic implications. Phosphate appears to be an essential factor in the restoration of the cells' normal chemical structure. If effective methods of providing phosphate can be found, the treatment of acidosis may be extended beyond the confines of the inactive plasma and extracellular fluids and into the regions of active cellular metabolism.

#### ADDISON'S DISEASE

Loeb<sup>24</sup> and Loeb, Atchley and Parson<sup>25</sup> have

called attention to and carefully analyzed the abnormal pattern of the blood serum in Addison's disease. The abnormalities commonly found are a decrease in serum sodium and glucose concentrations and an increase in the concentrations of serum potassium and nonprotein nitrogen.

The marked increase in the urinary excretion of sodium and chloride in Addisonian crises and the restoration of normal excretion by use of cortical extracts have been described by several groups of workers.<sup>62 64</sup>

The beneficial effects of the ingestion of sodium chloride in such amounts as will maintain normal plasma concentrations and salt balance have been demonstrated by Loeb and his co-workers,<sup>65 66</sup> Harrop, Soffer, Nicholson and Strauss<sup>67</sup> and others. The desirability of a restricted potassium intake as recommended by Wilder, Snell, Kepler, Rynearson, Adams and Kendall<sup>68</sup> has not been confirmed by general experience.

Loeb, Atchley, and Parson<sup>25</sup> concluded that a decrease in serum sodium concentration was the most sensitive chemical criterion of adrenal insufficiency in man. Harrop and his co-workers<sup>67</sup> have suggested the use of a salt-free diet as a diagnostic test. During the period of salt restriction, which is usually from three to five days, the patient is observed for symptoms of an Addisonian crisis, for a decrease in plasma sodium and chloride and for a high urinary chloride excretion. Because the test may provoke a serious crisis, they call attention to the necessity of the closest medical supervision. Zwemer and Truszkowski<sup>69</sup> suggested the diagnostic procedure of feeding 10 to 20 mg of potassium per pound of body weight and determining the concentration of potassium in the serum at frequent intervals. Wilder and co-workers<sup>68</sup> suggested the ingestion of potassium as a means of provoking an increased excretion of sodium and potassium.

However, chemical studies to determine serum concentrations and urinary excretions under the controlled conditions mentioned above provide confirmatory, not specific, evidence for the diagnosis of Addison's disease, and entail appreciable risk to the patient. The changes in the chemical composition of serum and the negative sodium and chloride balances which occur in Addison's disease are frequently observed in nephritis,<sup>19-23</sup> as thenia,<sup>70</sup> dehydration<sup>15 16 71</sup> and uncontrolled diabetes.<sup>14 17 18</sup> The ingestion of potassium salts by the nephritic patient may be associated not only with an increase in plasma potassium and urinary sodium excretion but also with serious untoward symptoms.<sup>72-76</sup>

More recently Cutler, Power, and Wilder<sup>77</sup> have described a simplified procedure for the diagnosis of Addison's disease. The test involves the administration of standard amounts of water and potassium and sodium chloride for two days and the determination of the concentration of sodium or chloride in the urine the morning of the third day. Because the analysis of chloride in urine is easier than that of sodium, chloride alone usually is determined. Urinary concentrations of chloride greater than 63 milliequivalents per liter are stated to indicate adrenocortical deficiency. The specificity of this test still needs verification by demonstrating its ability to distinguish Addisonian patients from those with the conditions mentioned above who tend to excrete large amounts of sodium and chloride in the urine, even in the presence of low sodium and chloride concentrations.

Moreover, the repeated observation of Addisonian crises with hemoconcentration and diminished plasma volume, without a decrease in the serum sodium concentration and without a loss of body sodium, chloride or water by way of the urine, suggests the important role that abnormal distribution of water and electrolytes may play in this disease.<sup>23-28,80</sup> Data are not yet available which are adequate to show that the determination of the total plasma sodium (as measured by the plasma volume and sodium concentration) is a more satisfactory criterion of Addison's disease than are serum concentration and urinary excretion values.

The recent work of Thorn, Engel and Eisenberg<sup>81</sup> with desoxy-corticosterone gives promise that this synthetic product will provide more economical and effective therapy than any now available.

## CASE 25201

## PRESENTATION OF CASE

A twenty-seven-year-old single male office worker was admitted complaining of loose bowel movements of one and a half years' duration.

Vague gas pains, coming on usually about 3 p.m. and relieved by changing position or massaging the abdomen, had been noted about one and a half years prior to admission. They were felt in the right upper quadrant over an area the size of the patient's hand. He then began to lose weight gradually in spite of a good appetite and an adequate diet. He gradually developed loose stools which contained mucus and, ten months before entry on two separate occasions, blood streaks. He had noticed none of these since that time. Six months before admission he was having four or five loose movements a day and occasionally one at night. These continued until two months before entry at which time they decreased to one or two movements a day though still associated with mucus. There was no significant pain. He had eaten fruits, vegetables and meat but avoided milk because it seemed to increase the mucus.

His past and family histories were noncontributory.

Physical examination showed a markedly undernourished man who appeared to be slightly anemic. Examination of the head and chest was negative. The blood pressure was 110 systolic, 70 diastolic. There was slight tenderness above and to the right of the umbilicus.

The temperature was 97.4°F, the pulse 120, and the respirations 20.

Examination of the urine was negative. The blood showed a red-cell count of 3,270,000 with 60 per cent hemoglobin, and a white-cell count of 12,400 with 85 per cent polymorphonuclears. The serum protein was 6.4 gm per 100 cc. A blood Hinton test was negative. The sedimentation rate was 18 mm in fifteen minutes, 40 mm in thirty minutes, 50 mm in forty-five minutes, 56 mm in sixty minutes. Numerous stool examinations were negative for blood and for parasites.

X-ray films of the chest were negative. The upper gastrointestinal tract was normal. The barium passed through the small bowel rapidly. The terminal ileum showed abnormal mucosa, appear-

ing nodular proximally and destroyed in the region of the ileocecal valve. There was no "string sign," the ileum being of normal caliber. The ileocecal valve was elongated and irregular. A barium enema showed that the colon was grossly abnormal. The ascending colon showed numerous rounded and irregular filling defects, in places these simulated polyps, while in other areas the defects were plateau-like and larger. A flat mass measuring up to 3 cm in diameter was seen just proximal to the hepatic flexure. The margins of the ascending colon showed fine, irregular projections simulating ulcerations. These apparent ulcerations were spotty in distribution, some of them being seen in the descending colon as far as the crest of the ileum, whereas parts of the transverse colon were fairly normal. The sigmoid and rectum were essentially normal.

On the third hospital day proctoscopy was done. The mucosa was granular and injected but not thickened or edematous. There were no ulcerations or hemorrhagic areas.

Transfusions, vitamins and a high caloric diet brought about little improvement. On the fifty-third hospital day an operation was performed.

## X-RAY INTERPRETATION

DR. AUBREY O. HAMPTON: This was an interesting case. I did the examination, and I was particularly impressed by the location of the changes in the colon and the size of the polypoid defects. Then there was a segment in the transverse colon which was fairly normal, and another area of smaller ulcerations at the splenic flexure and at the beginning of the descending colon which faded out toward the sigmoid. These polypoid-appearing lesions are quite definite and involve the whole ascending colon and hepatic flexure. In some films taken during fluoroscopy with pressure on the lesion there seemed to be one solid plateau or one elevation separate from the polyps. I think it is possible that pressure caused multiple polyps to blend into one another and to produce a defect similar to a flat mass. You can see there that the surface is granular. The colon is small in the proximal portion but of normal caliber from there on. The ileum shows an area of disease near the valve, but even there it is not constricted. The valve is elongated and irregular. The small bowel is normal. The chest was normal.

## DIFFERENTIAL DIAGNOSIS

DR. E. PARKER HAYDEN: This story is more suggestive of an inflammatory process than it is of malignant disease. The laboratory findings were essentially negative except for a slight leukocytosis and a somewhat rapid sedimentation rate.

which suggest infection. The stools were negative for blood, parasites and amebae.

The gastrointestinal x-ray findings are quite clear and yet it is difficult to make a definite diagnosis from them. The chest films were negative, while such a finding suggests that the intestinal condition was not due to tuberculosis, this is not necessarily so. The lack of a "string sign" in the ileum does not rule out regional ileitis because this is simply an indication of a very narrow ileum with marked spasm. Not all cases of regional ileitis exhibit this picture. The defects which appear in the x-ray resemble real polyps rather than the pseudopolyps which occur in ulcerative colitis and represent islands of ragged mucosa in the midst of areas of destruction. On the other hand, some cases of ulcerative colitis develop true adenomatous polyps.

We hear more and more about resections in regional ulcerative colitis which can occasionally be done when the lesions involve only the right colon. This patient was proctoscoped, and a note made that the mucosa was injected and granular but not thickened and edematous. I cannot accept this statement as correct because if the mucosa is granular I believe that it is always thickened. If the mucous membrane of the rectum were really granular, I should consider it diagnostic of mild ulcerative colitis. It is a question of the interpretation of that particular proctoscopy. I believe there is not much doubt that this patient had an ulcerative process which involved largely the right colon and the ileum. It has been thought that there may be a relation between ulcerative colitis and regional ileitis. One patient whom I had previously proctoscoped and on whom I had made a definite diagnosis of ulcerative colitis was operated on subsequently by another surgeon who resected two isolated areas of what he considered to be typical regional ileitis.

There is one other possible diagnosis to be considered—multiple polyposis. In this disease, although diarrhea accompanies it, we ordinarily do not see inflammatory changes of any extent in the mucosa. Furthermore, polyps are almost always present in the rectum. There were none in this case. Multiple polyposis is a familial disease and does not fit the picture in this case.

I believe the most likely diagnosis is an ulcerative inflammatory process of the right colon, of non-specific rather than tuberculous origin, with secondary polyposis.

DR CHESTER M. JONES. When this young man came into the hospital the story was very suggestive of a partially obstructive process in the region of the terminal ileum, and before we heard

the results of x-ray study, I wondered whether he did not have terminal ileitis or tuberculosis of the ileocecal region. Proctoscopy showed just about what was described in the protocol, but I should have added the note that the rectosigmoid looked more as if it were irritated secondarily from some process higher up than as if there were primary disease in that area. I think occasionally one gets a confusing picture of irritation and even partial superficial erosion which is not due to ulcerative colitis. The x-ray films certainly showed trouble in the region of the ileocecal valve but much more in the colon than I anticipated, and before operation it seemed to me that there was still a possibility of a tuberculous process. The obvious thing to my mind was that this boy was terribly undernourished. We decided that as soon as we got him in decent shape he would have to have an ileostomy and a resection of a large part of the bowel, how much, only to be determined at operation. If I remember correctly, when I went over the films with Dr. Hampton we agreed that there was involvement of the upper portion of the ascending segment of the colon but that there was also something in the region below the splenic flexure.

DR. ARTHUR W. ALLEN. Before operation I thought of all the possibilities that Dr. Hayden has mentioned, and we did put a good deal of stress on the splenic flexure. You may have forgotten it, Dr. Hampton, but we found areas in this region that were definitely diseased. At exploration it was very interesting that the transverse colon was as normal as any large bowel I have ever seen. His ascending colon was diseased and his descending colon was involved almost to the rectosigmoid junction. There was this definite skip of the transverse colon. So far as you could tell grossly the involved bowel could have been diseased by any one of the processes which Dr. Hayden has mentioned. Inasmuch as the rectum had appeared quite normal by proctoscopic examination and also seemed fairly normal to palpation, the ileum was transected and the proximal end anastomosed to the rectosigmoid. He did reasonably well aside from an ischiorectal abscess, but did not gain so much as we thought he might. After removing his right colon, at a second operation, he picked up fairly rapidly and gained as much as a pound a day, so that he was in a practically normal state of nutrition at the time of discharge. In view of the definite lesions in the descending colon it is difficult to explain why he has done so well, perhaps this is due to better drainage of this segment, or simply to less disease.

## CLINICAL DIAGNOSIS

Regional ileitis?  
Ulcerative colitis?

## DR. HAYDEN'S DIAGNOSIS

Non-specific ulcerative ileocolitis

## ANATOMICAL DIAGNOSES

Ulcerative colitis  
Adenomatous polyps?

## PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY The specimen showed all the usual features of a typical ulcerative colitis and, in addition, a marked polypoid hypertrophy of the remaining mucosa, in fact more marked than any we have ever seen. Some of the polyps were large enough, I think, to be considered adenomatous polyps. Between them there were characteristic areas of inflammatory thickening of the mucosa, of ulceration and of scarring of the muscular and serosal layers. There was nothing to suggest carcinoma.

DR. HAYDEN What was the flat mass 3 cm in diameter described in the x-ray—a cluster of polyps?

DR. MALLORY I should think that was it. We found nothing else that would explain it.

DR. ALLEN Do you want to say how many cases of ulcerative colitis of this degree you have seen without involvement of the rectum?

DR. MALLORY Very few if any.

DR. ALLEN How about you, Dr. McKittrick?

DR. LELAND S. MCKITTRICK I have never seen one.

DR. ALLEN Dr. Jones, is it new to you?

DR. JONES Yes.

DR. ALLEN And you, Dr. Urmey?

DR. THOMAS V. URMAY I have never seen it.

DR. ALLEN That is why I thought it must be something else and why I connected the rectosigmoid with the terminal ileum. I have seen only one other patient that had had it done, and his rectum finally had to be removed.

DR. HAMPTON Certainly it is an unusual x-ray appearance. I do not believe you could get one out of a hundred to say that the lesion was due to ulcerative colitis.

told that he had a right kidney stone, the diagnosis having been established by x-ray examination. Six months before admission he first noted a small mass high in his right upper quadrant, beneath the costal margin. It was non-tender and caused no symptoms. Six weeks before entry he first noticed that his urine contained blood. He continued having hematuria intermittently with no urinary symptoms except occasional frequency. Three weeks later he noted that the mass was the size of an orange. It continued to grow until it occupied most of his right upper and lower quadrants. It was not tender, was movable and caused a dragging sensation while standing. His hematuria continued but was his only urinary complaint. He had been unable to eat anything but milk and eggs during the previous few weeks and had lost 20 pounds in weight during the two months before entry. He had had no other gastrointestinal symptoms, having had regular normal bowel movements and no evidence of blood in the stools. His past and family histories were non-contributory.

Physical examination showed a tall, nervous man weighing 200 pounds. Examination of the chest was negative. The blood pressure was 150 systolic, 95 diastolic. The abdomen contained a large soft mass the size of a football extending from the right upper quadrant down past the iliac crest. It was freely movable, non-tender and smooth, and descended with respiration.

The temperature was 99.5°F, the pulse 80, and the respirations 20.

The urine examination showed a specific gravity of 1.025, a trace of albumin, no casts, an occasional white blood cell and numerous red cells. Culture showed a moderate growth of *Staphylococcus aureus*. The blood showed a red-cell count of 5,000,000 with 100 per cent hemoglobin, and a white-cell count of 8000. The nonprotein nitrogen of the serum was 26 mg, the chloride 97 milliequivalents, the carbon-dioxide combining power 55.3 vol, the protein 6.4 gm and the sugar 97 mg per 100 cc. A blood Hinton test was negative. The serum calcium was 8.92 mg per 100 cc., the phosphorus 3.64 mg.

X-ray films of the chest and skull were negative. A flat abdominal film showed a large mass in the right abdomen extending from above the costal border to the crest of the ilium. No kidney shadow was visible outside of this mass. There was an ovoid area of calcification 2.5 by 1.5 cm overlying the right side of the sacrum. The right half of the pelvis, the right femur and the fourth lumbar vertebra showed evidence of extensive Paget's disease. An intravenous pyelogram showed prompt excretion of the dye on the left, filling a nor-

## CASE 25202

## PRESENTATION OF CASE

A fifty-six-year-old married Italian barber was admitted complaining of an abdominal mass of six months' duration.

Twenty-two years prior to entry the patient was

mal kidney pelvis and ureter. No excretion was visible on the right side after thirty minutes. After injection of the lower part of the right ureter through a catheter, the tip of the catheter lay just above the ureterovesicular orifice. The injected material passed upward to the area of calcification and showed the lower ureter to be grossly abnormal. Multiple irregular filling defects were demonstrated in the dilated ureter between the area of calcification and the ureterovesicular orifice.

On the fourth hospital day an operation was performed.

#### DIFFERENTIAL DIAGNOSIS

DR. FLETCHER H. COLBY. The significant points in the patient's history are the diagnosis of right renal stone twenty-two years previously, the patient's observation of a tumor in the right upper quadrant six months before admission, and the fact that this tumor had increased rapidly in size during the past six weeks. Hematuria had been present for at least six weeks. The absence of severe pain is also a feature of the history. Physical and x-ray examinations seem to localize this mass to the right kidney, since no function could be demonstrated by intravenous pyelogram and no kidney outline was visible by x-ray. Hematuria in the majority of instances is due to tumor or tuberculosis. Other causes are inflammatory lesions, polycystic kidneys and certain systemic conditions such as purpura. I believe that the uncommoner causes of bleeding can be excluded by the normal laboratory findings and the x-ray examination. Tuberculosis does not merit serious consideration because of the noncontributory past and family histories and the absence of a marked degree of bladder irritability.

A renal stone was demonstrated by x-ray twenty-two years before, and the findings at entry were those of stone in the right ureter with hydronephrosis. The most reasonable explanation of the rapid growth of this tumor is the development of hydronephrosis. The diagnosis of stone and hydronephrosis would satisfactorily account for the symptoms and the findings in this patient with the exception of the x-ray appearance of the lower portion of the right ureter. These filling defects cannot be disregarded. They suggest papillary tumor, which is either primary in the ureter itself or possibly has grown down from the kidney pelvis and involved the ureter. A primary tumor of the ureter is a very unusual condition, but I do not see why it could not be present in this patient. I cannot go farther in the way of diagnosis without seeing the x-ray films.

In this film there is a large area of calcifica-

tion in the right ureter. I assume the bone changes are those of Paget's disease and not due to metastatic carcinoma, although I do not know how to tell the difference. My diagnosis is primary carcinoma of the ureter.

#### CLINICAL DISCUSSION

DR. GEORGE G. SMITH. I do not remember whether we suspected a ureteral carcinoma when we operated on this patient. I think we did not, because I operated on him, and as I remember it, I was somewhat surprised at the findings. I went in to do a nephrectomy and found a big hydronephrotic kidney which I took out. The ureter was dilated down to the pelvic brim. We passed a uterine sound down the ureter to find out where the stone was, and ran into an obstruction. I palpated the ureter and found a solid mass filling the ureter from a point just above the pelvic brim to one down over the brim. At that time I realized that we had a carcinoma of the ureter, so I tied the upper end of the ureter, closed the kidney wound, put the patient on his back and made a midline incision, stripping the peritoneum inward. I picked up the ureter, which was the size of my thumb, it was easily freed down to the bladder, as is so often the case with these tumors. Since it seemed to be normal for several centimeters above the point of entrance into the bladder, I did not make an elliptical incision including the entire right ureteral ridge but cut off the ureter just at the bladder wall and removed the lower portion of it.

This patient came in yesterday to the Tumor Clinic. He looks fine and feels perfectly well. I think he must have Paget's disease in the bones because he had no complaints. I asked him if he had bled, and he said that two weeks ago he had seen a few blood flecks in the urine. We cystoscoped him, and up in the dome of the bladder we found two small papillary tumors. I could feel no mass in the operative region. On bimanual rectal examination there seemed to be no thickening in the right side of the pelvis, but of course these cases of primary carcinoma of the ureter that get well are few.

#### CLINICAL DIAGNOSES

Right ureteral stone  
Hydronephrosis

#### DR. COLBY'S DIAGNOSES

Primary carcinoma of the ureter  
Hydronephrosis  
Ureteral calculus

## ANATOMICAL DIAGNOSES

Primary papillary carcinoma of the ureter  
Ureterolithiasis  
Hydronephrosis

## PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY The lumen of the ureter was greatly dilated around a stone, and the stone itself was completely embedded in shaggy papillary masses of neoplastic epithelium. There was no gross or microscopic invasion of the wall that we could make out. The kidney lesion was a simple hydronephrosis, and there was no evidence of papillary tumor in the pelvis, so that there is no doubt in this case that the tumor was primary in the ureter. The later appearance of papillomas in the bladder, way up in the dome and nowhere near the mouth of the ureter, suggests, as do so many of these cases, that one is dealing with an underlying disease of the transitional epithelium that lines the entire urinary tract. This is evidenced by a tendency to the formation

of papillary neoplasms throughout the tract, and in many cases the reappearance of tumor has to be looked on as a new primary tumor and not metastasis. In this case I should think that that was almost certainly true.

How would you feel about that, Dr Smith?

DR SMITH The point against that is the fact that there are no papillomas in the other kidney and yet they are present in the bladder. I agree with you that it does seem as if there were some predisposing condition of the bladder mucosa that makes these tumors develop. That is a line of argument I have used regarding many bladder carcinomas, but I do not know that it applies in this case. I could not believe that it was due to a bit of tumor being borne down the ureter and being implanted, but that is possibly the case.

DR MALLORY Primary carcinoma of the kidney pelvis or ureter is an extremely rare disease, and on a statistical basis, one would not expect many patients to have it in both kidneys.

## ANNUAL MEETING

THIS issue of the *Journal* presents the complete program of the one hundred and fifty-eighth annual meeting of the Massachusetts Medical Society, to be held in Worcester at the Municipal Memorial Auditorium, Tuesday, Wednesday and Thursday, June 6, 7 and 8. The Auditorium is ideally suited for the meeting. Surrounded by adequate parking facilities, it has one large hall to house the scientific and commercial exhibits, a theater in which to hold the consecutively run section meetings, rooms for discussion groups and committee meetings, and space available for a cafeteria where lunches will be served,—all the daytime program will be carried out under one roof. The evenings' events, the Shattuck Lecture

and the annual dinner, will be held at the Hotel Bancroft.

The changed form of this year's program for the section meetings should receive the attention of the fellows of the society, and it is hoped, their approval. All the section meetings are to be held in the Little Theater of the Auditorium. Unlike former years, these meetings are to be consecutive general assemblies with no two sections holding simultaneous meetings. Not only does such an arrangement promise a large attendance at the individual section meetings, but the fellows will be enabled to attend any or all the meetings without the necessity of missing one of two topics in which they are interested, an inevitable occurrence while more than one of the sections were meeting simultaneously as under the form of program previously followed.

In 1937 a day devoted to a combined clinical meeting was introduced to our program. Its success both then and last year was definite. This year a somewhat different plan has been developed by the Worcester committee for Wednesday, June 7. The morning is to be taken up by a combined meeting at which Dr. Richard B. Cattell, of Boston, Dr. Arthur M. Fishberg, of New York City, Dr. Walter C. Alvarez, of Rochester, Minnesota, and Dr. Emil Novak, of Baltimore, will present subjects of interest and importance to physicians regardless of whether they are engaged in the practice of general medicine or of the specialties. Wednesday afternoon is to be devoted to round table discussions. Three of these will be run simultaneously with a change of subject every hour. The nine subjects to be discussed are "Cranio-cerebral Injuries," "Heart Disease," "Hyperthyroidism," "Pneumonia," "Low-Back Pain," "Peripheral Vascular Disease," "Urinary Infections," "Neonatal Injuries" and "Adolescent Prepsychotic Conditions."

The entire program of this year's annual meeting has been worked out thoughtfully with one chief objective to present to the fellows of the Society through the medium of speakers of wide experience in their respective fields more or less specialized subject matter of general importance.

## SPEAKING OF BATH TUBS

A TREATISE could be written on the impact of plumbing on American life and morals, to say nothing of our art and letters. Not too many years ago this influence was practically nil, the lead pipe and the tin tub were viewed askance by the virile majority of our ancestry, at a time when the flush toilet was considered in many quarters as little short of immoral.

As wealth accumulated and men decayed, an easier attitude was adopted toward hot and cold running water, it was conceded that cleanliness could still be a virtue, even if not attained under the barnyard pump with a bar of laundry soap and a curry comb. The plumber was accepted as a member of society and admitted to many churches in good standing, although, as a class, the knights of the Sullson wrench were still held up as models of clumsiness. As late as 1920 the likening of a surgeon to a plumber constituted fighting words, and even members of the new genitourinary specialty were inclined to be annoyed. Since the panic of 1929, anyone who can charge for his time while going back to the office after a forgotten blow torch is held in high esteem, and many an erstwhile banker has surreptitiously learned how to change a faucet washer and sweat a mean joint.

The bath tub is, of course, no innovation. Many Pompeians and Herculaneans were caught at the bath when proud Vesuvius erupted, and Gibbon practically attributed the decline and fall of the Roman empire to the prevailing use of the hot bath at that period of history. Warm baths are so relaxing!

Are we to meet a like fate? It is the thought that tortures us when we read in *The Commentator* that since 1900 more than 16,250,000 bath tubs have been manufactured and sold in this country. If cleanliness has come that close to godliness since the turn of the century, then woe betide us!

We recall (editorially speaking) a circular tin affair, about six inches in depth, that our paternal ancestor once had built for his personal use, plagiarizing on an English model. It was filled, pail after pail, by a perspiring servant, and was a far cry from the nited pleasantries of the twittering twenties, but still, the menace was there.

There are no two ways about it. Plumbism has its insidious dangers. We (editorially speaking) are reminded of a family that kept a tame otter by the name of Josephine. Apparently otters are readily tamed, except for certain atavistic tendencies. Uninitiated guests, on asking for the privilege of washing (sic) before dinner, would be confused and a little bewildered by finding on the bathroom door a neatly lettered placard "Please keep the door shut, as Josephine likes to sleep in the toilet."

## MASSACHUSETTS MEDICAL SOCIETY

## LEGISLATIVE NOTES

*House Bill 2151* This bill to license chiropractors was reported by the Committee on Public Health no legislation necessary. However, there were seven dissenters. Actually it was a tie vote, as Senator Olander, of Northampton, did not vote, being absent because of sickness. The names of the dissenters were Senators Montminy, of Lowell, and Skibinski, of Chicopee, and Representatives Bessette, of New Bedford, Brooks, of Lawrence, Jordan, of Revere, Lunney, of Holyoke, and Stetson, of Middleboro. The legislators who voted against the chiropractors were Senator McCooley, of Worcester, and Representatives Bergeron, of Amherst, Cutler, of Needham, Kaplan, of Boston, Kelley, of Worcester, Vaughan, of Belmont, and Whitcomb, of West Boylston.

It may be seen from this list that the Worcester District Medical Society has done the most effective legislative work in connection with this bill.

On May 16, at the third reading of the bill in the House, the committee's report of no legislation necessary was accepted, and since this report was unfavorable, the bill has been referred to the Senate for concurrence.

CHARLES C LUND, *Chairman*

## DEATH

CABOT—RICHARD C CABOT M.D., of 101 Brattle Street, Cambridge, died May 8. He was in his seventy-second year.

He received his degree from the Harvard Medical School in 1892. Dr. Cabot was made an assistant professor in medicine at Harvard Medical School in 1899 and in 1918 was raised to a full professor of clinical medicine. Two years later he was appointed professor of social ethics at Harvard University and held that position until his retirement in 1934.

Dr. Cabot was affiliated with the Massachusetts General Hospital and was a member of the consulting staff at the time of his death. He was also a consultant at the New England Hospital for Women and Children, the Westboro School for Boys and the Lancaster School for Girls. In 1905 he inaugurated a social service department at the Massachusetts General Hospital; the value of this type of work was soon appreciated and such departments were subsequently established in the majority of the large hospitals of the country.

Among his affiliations were fellowships in the Massachusetts Medical Society, the American Medical Association and membership in the Association of American Physicians.

Two brothers, Dr. Hugh Cabot and Philip Cabot, survive him.

## THE ONE HUNDRED AND FIFTY-EIGHTH ANNIVERSARY

Tuesday, Wednesday and Thursday, June 6, 7 and 8

Municipal Memorial Auditorium and Hotel Bancroft, Worcester

The exercises of the one hundred and fifty-eighth anniversary of the Society will be held in Worcester, on June 6, 7 and 8, at the Municipal Memorial Auditorium and the Hotel Bancroft. Members of the medical profession are cordially invited to attend.

The general arrangements for the meeting have been made by the Committee of Arrangements, consisting of Drs. Richard P. Stetson, chairman, Augustus Thorndike, Jr., Edward J. O'Brien, William T. O'Halloran and James A. Halsted. The local arrangements have been in charge of committees from the Worcester District Medical Society, with Dr. Charles A. Sparrow acting as general chairman and Dr. James C. McCann, as assistant chairman. The chairmen of the various local subcommittees are as follows:

COMBINED GENERAL MEETING AND ROUND TABLE DISCUSSIONS Dr. James C. McCann.

SCIENTIFIC EXHIBITS Dr. William J. Elliott.

PUBLICITY Dr. Philip H. Cook.

TRAFFIC AND PARKING Dr. Robert J. Northbridge.

SECTION MEETINGS AND AIDS Dr. George R. Dunlop.

GOLF Dr. Julius J. Tegelberg.

REFRESHMENTS Dr. Henry L. Kirkendall.

ENTERTAINMENT Dr. George C. Tully.

LADIES COMMITTEE Mrs. Charles A. Sparrow.

The registration desk will be on the stage of the Worcester Municipal Memorial Auditorium.

All section and combined meetings, as well as that of the Council, the annual meeting, commercial and scientific exhibits, and luncheons will be held in the Municipal Memorial Auditorium.

The Shattuck Lecture and the annual dinner will be held at the Hotel Bancroft.

The scientific and commercial exhibits will all be located in the main hall of the Auditorium.

A special telephone switchboard and operator will be installed in the Auditorium for the use of the fellows. The telephone number will be WORCESTER 3-1401. Please use this number.

A cafeteria will be maintained in the Auditorium for the use of those attending these meetings.

A golf tournament will be held at the Wachusett Golf Club on June 6 and 7.

Moving pictures of medical subjects will be shown throughout the meeting.

Windshield stickers will be sent to all fellows and cars bearing this sticker will be shown special parking consideration by the Police Department of the City of Worcester.

### TUESDAY, JUNE 6

#### SECTION OF MEDICINE

9 45 to 11 15 o'clock

Little Theater, Worcester Memorial Auditorium

Dr. Edward P. Baggs, Holyoke, *Chairman*

Dr. Erwin C. Miller, Worcester, *Secretary*

1 *The Importance of Hypochromic Anemia* Dr. William P. Murphy, Boston

2 *The Role of Oxygen in the Treatment of Pneumonia* Dr. Alexander M. Burgess, Providence, Rhode Island (by invitation)

3 *Atypical Pneumonia of Unknown or Possibly Virus Etiology* Dr. Michael E. Murray, Jr., Cambridge and Boston.

Committeeman in-charge Dr. William T. O'Halloran, aids, Drs. Roger W. Robinson and George C. Erickson.

#### SECTION OF DERMATOLOGY AND SYPHILOLOGY

11 30 to 1 00 o'clock

Little Theater, Worcester Memorial Auditorium

Dr. E. Lawrence Oliver, Boston, *Chairman*

Dr. John G. Downing, Boston, *Secretary*

1 *Chairman's Address* Dr. E. Lawrence Oliver, Boston.

2 *Latency and Wassermann Fastness* Dr. Paul A. O'Leary, Mayo Clinic, Rochester, Minnesota (by invitation)

3 *The Indications and Contraindications of Roentgen Rays in Dermatology* Dr. C. Guy Lane, Boston

Committeeman in-charge Dr. James A. Halsted, aids, Drs. Gerald J. Sullivan and Gerald Shelby

#### SECTION OF PEDIATRICS

2 00 to 3 30 o'clock

Little Theater, Worcester Memorial Auditorium

Dr. Elmer W. Barron, Malden, *Chairman*

Dr. James M. Baty, Belmont and Boston, *Secretary*

1 *Non-Specific Therapy* Dr. Francis C. McDonald, Stoneham and Boston.

2 *Specific Therapy* Dr. Edward C. Curnen, Boston (by invitation) and Dr. John A. V. Davies, Boston.

Discussion Dr. Maxwell Finland, Boston.

Committeeman in-charge Dr. Augustus Thorndike, Jr., aids, Drs. Smith G. Philips and Harry B. Goodspeed.

#### SECTION OF RADIOLOGY AND PHYSIOTHERAPY

3 45 to 5 15 o'clock

Little Theater, Worcester Memorial Auditorium

Dr. Herman A. Osgood, Boston, *Chairman*

Dr. Edward C. Vogt, Boston, *Secretary*

1 *Physical Therapy in the Treatment of Fractures* Dr John S Coulter, professor of physical therapy, Northwestern University Medical School, Chicago, Illinois (by invitation)

2 *The Value of X Ray in the Treatment of Infections and Inflammatory Conditions* Dr Arthur U Desjardins, Mayo Clinic, Rochester, Minnesota (by invitation)

Committeeman in-charge Dr Edward J O'Brien, aids, Drs Herman L. Matern and Charles V King

8 00 o'clock

Ballroom, Hotel Bancroft

THE SHATTUCK LECTURE

*Epilepsy and the Cerebral Lesions of Birth and Infancy* Dr Wilder Penfield, Montreal, director, Montreal Neurological Institute and professor of neurology and neurosurgery, McGill University Faculty of Medicine, Montreal.

Light refreshments will be served after the lecture.

Committeeman in-charge Dr James A Halsted, aid, Dr Henry L Kirkendall.

\* \* \*

WEDNESDAY, JUNE 7

COMBINED MEETING

9 00 to 1 00 o'clock

Little Theater, Worcester Memorial Auditorium

Dr James C McCann, Worcester, *Chairman*  
Dr James A. Halsted, Dedham, *Vice Chairman*

9 00 o'clock

*Obstructing Lesions of the Large Bowel* Dr Richard B Cattell, Boston.

10 00 o'clock

*Cardiac and Circulatory Failure* Dr Arthur M. Fishberg, New York City (by invitation)

10 45 o'clock

*Diagnostic Services for Equine Encephalomyelitis* Dr Roy F Feemster, Massachusetts Department of Public Health.

11 00 o'clock

*Management of the Nervous Patient* Dr Walter C Alvarez, Mayo Clinic, Rochester, Minnesota (by invitation)

12 00 o'clock

*Endocrines and Endocrine Therapy in Gynecology* Dr Emil Novak, Baltimore (by invitation)

Committeeman in-charge Dr James A Halsted, aids, Drs Arthur C Brassau, Thomas Hunter, Edward Budnitz and Franklyn P Bousquet

SUPERVISING CENSORS ANNUAL MEETING

10 00 o'clock

Green Room, Worcester Memorial Auditorium

ANNUAL MEETING OF COUNCIL

10 30 o'clock

Stage, Worcester Memorial Auditorium

This meeting will be followed by the Cotting Luncheon to councilors Should the council meeting be prolonged, the councilors will reconvene for an adjourned meeting.

Notices of the meeting, with the order of business, will be mailed to councilors on May 29

Committeemen in-charge Council Meeting, Dr Richard P Stetson, aid, Dr George C. Tully, Cotting Luncheon, Dr Edward J O'Brien, aid, Dr Henry L. Kirkendall.

ROUND TABLE DISCUSSIONS

Worcester Memorial Auditorium

2 00 to 3 00 o'clock

LITTLE THEATER

*Cranocerebral Injuries* Chairman, Dr Donald Munro, Boston, collaborators Dr John S Hodgson, Boston, and Dr Joseph Hahn, Springfield

ROOM A

*Heart Disease* Chairman Dr Samuel A Levine, Boston, collaborators Dr Howard B Sprague, Boston, and Dr James Z Naurison, Springfield.

ROOM B

*Hyperthyroidism* Chairman Dr Howard M. Clute, Boston, collaborators Dr Lewis M. Hurvthal, Boston, and Dr Jacob Lerman, Boston.

3 00 to 4 00 o'clock

LITTLE THEATER

*Pneumonia* Chairman Dr Donald S King, Boston, collaborators Dr Raymond H Goodale, Worcester, and Dr Elliott S A. Robinson, Boston.

ROOM A

*Low Back Pain* Chairman Dr Louis E. Phaneuf, Boston, collaborators Dr John W O'Meara, Worcester, and Dr James B Ayer, Boston

ROOM B

*Peripheral Vascular Disease* Chairman Dr Reginald H. Smuthwick, Boston, collaborators Dr John B. Sears, Boston, and Dr Robert R. Linton, Boston.

4 00 to 5 00 o'clock

LITTLE THEATER

*Urinary Infections at Different Ages* Chairman Dr E. Granville Crabtree, Boston, collaborators Dr Roger C Graves, Boston, and Dr Lester M Felton, Worcester

## ROOM A

*Neonatal Injuries* Chairman Dr Joseph W O Connor, Worcester, collaborators Dr James S P Beck, Worcester, and Dr Randolph K. Byers, Boston.

## ROOM B

*Adolescent Prepsychotic Conditions* Chairman Dr R. P. Kemble, Worcester, collaborators Dr George P Reynolds, Boston, and Dr Frederick Rosenheim, Boston.

Committeemen in-charge Little Theater, Dr James A Halsted, aids, Drs John T Carmody, John B Butts and Frank B Carr, Rooms A and B, Dr Augustus Thorndike, Jr, aids, Drs Carroll W Johnson, Edwin B Seelye, Leroy E. Mayo, Theodore B Massell, Edward S Ramsdell and Clifford Guptill.

## ANNUAL DINNER

7 15 o'clock

Ballroom, Hotel Bancroft

Tickets for the dinner (price \$1 00) should be obtained at the Registration Desk.

Committeeman in-charge Dr Edward J O'Brien, aid, Dr Charles A. Sparrow

\* \* \*

THURSDAY, JUNE 8

## SECTION OF OBSTETRICS AND GYNECOLOGY

9 00 to 10.30 o'clock

Little Theater, Worcester Memorial Auditorium

Dr Roy J. Heffernan, Boston, *Chairman*  
Dr M. Fletcher Eades, Boston, *Vice Chairman*  
Dr Raymond S. Titus, Boston, *Secretary*

- 1 *A Resume of Maternal Mortality Study in the State of Massachusetts for the Year 1938* The Secretary of the Section
- 2 *Rupture of the Uterus* Dr Frederick J. Lynch, Boston.
- 3 *Obstetric Analgesia* Dr Benjamin F. Cornwall, Salem  
Committeeman in-charge Dr William T. O'Halloran, aids, Drs Donald K. McClusky and Herbert E. Hedberg

## SECTION OF SURGERY

10 30 to 12 00 o'clock

Little Theater, Worcester Memorial Auditorium

Dr Benjamin H. Alton, Worcester, *Chairman*  
Dr Reginald H. Smithwick, Boston, *Secretary*

## SURGERY OF THE STOMACH AND DUODENUM

- 1 *Medical Aspects* Dr Chester M. Jones, Boston.
- 2 *Gastrosopic Examination* Dr Edward B. Benedict, Boston.
- 3 *X-Ray Examination* Dr William J. Elliott, Worcester

- 4 *Surgery of the Stomach* Dr Arthur W. Allen, Boston.
- 5 *Surgery of the Duodenum* Dr Frank H. Lahey, Boston.

Discussion by Dr Philemon E. Truesdale, Fall River, and Dr James C. McCann, Worcester

Committeeman in-charge Dr Richard P. Stetson, aids, Drs. John W. McKeon, Jr., and Earl E. Tophen

## ANNUAL MEETING

12 00 o'clock

Little Theater, Worcester Memorial Auditorium

Business of the Annual Meeting

Address by the President.

Annual Discourse *The Massachusetts Medical Society and Socialized Medicine* Dr Elliott P. Joslin, Boston

Committeeman in-charge Dr Augustus Thorndike, Jr., aid, Dr George C. Tully

At the close of the Annual Discourse, luncheon will be served to those who have obtained tickets at the Registration Desk.

Committeeman in-charge Dr William T. O'Halloran, aid, Dr Carroll W. Johnson

## LADIES PROGRAM

TUESDAY — JUNE 6

- 9 00–12 00 Registration, Worcester Memorial Auditorium.
- 12 00 Bus leaves main entrance of Auditorium for
  - 1 Luncheon at the Worcester Country Club
  - 2 The gardens of Mrs. Emory and Mrs. Gage in Shrewsbury
- 6 15 Dinner at the Worcester Club, 1 Oak Street.
- 8 00 Shattuck Lecture, Hotel Bancroft, by Dr Wilder Penfield, Montreal

WEDNESDAY — JUNE 7

- 9 00–12 00 Registration, Worcester Memorial Auditorium.
- 12 00 Bus will leave the Auditorium to take visitors to luncheon at the "Barn," Harvard, Massachusetts, and a tour of three museums
  - 1 Fruitlands (home of the Alcott family)
  - 2 Shaker Exhibit
  - 3 American Indian Museum

Tea will be served at the Museum Tea Room.

- 8 15 Ladies are invited to hear the speakers after the annual dinner of the Massachusetts Medical Society at the Hotel Bancroft. The gallery will be reserved for their use.

There will be no charge for any of the events. The women visitors will be the guests of the Massachusetts Medical Society and the Worcester District Medical Society

### MOVING PICTURES

Main Floor, Worcester Memorial Auditorium

Warren Sturgis, Director

#### TUESDAY — JUNE 6

- 10 00 *The Prevention and Treatment of Eclampsia*  
 10 45 *Complications of the Second Stage of Labor*  
 11 00 *The Treatment of Asphyxia Neonatorum*  
 11 30 *Intracranial Injuries of the Newborn*  
 12 00 *The Valves of the Heart in Action*  
 12 15 *The Heart Mechanism in Health and Disease*  
 12 30 *Ectopic Heart*  
 12 45 *Thrombi and Emboli*  
 1 00 *The Technic of Blood Transfusion*  
 1 30 *The Anemias*  
 2 00 *Intestinal Peristalsis*  
 2 15 *The Action of Drugs on Intestinal Motility*  
 2 30 *Bronchoscopy and Esophagoscopy on the Cadaver and on the Living*  
 2 45 *Obstructive Laryngitis*  
 3 00 *Oxygen Administration by the Oropharyngeal Catheter*  
 3 15 *Myasthenia Gravis*  
 3 30 *Teaching Diabetics*  
 3 45 *Development of the Fertilized Rabbit's Ovum*  
 4 00 *The Diagnosis and Treatment of Syphilis*  
 4 30 *A New Day (Pneumonia Serum Treatment)*

#### WEDNESDAY — JUNE 7

- 10 00 *Child Guidance Work*  
 10 15 *Reconstruction of Crippled Hands*  
 11 00 *Pneumonectomy*  
 11 15 *Empyema*  
 11 30 *Diagnostic Procedures in Tuberculosis*  
 11 45 *On the Firing Line (Tuberculosis Public Health Work)*  
 12 00 *Hernia Clinical and operative aspects*  
 12 30 *The Mechanics of Appendicitis*  
 12 45 *Appendectomy for Acute Gangrenous Appendicitis*  
 1 00 *Treatment of Burns*  
 1 30 *First Aid for Safe Transportation of Fractures of the Long Bones*  
 1 45 *Treatment of Fractures in Children*  
 2 00 *Bone Plating of Fractured Radius*  
 2 15 *Protruded Intervertebral Disk*  
 2 30 *Aftercare of Poliomyelitis*  
 3 00 *Lower Limb Amputation and Aftercare of the Patient*  
 3 30 *Human Sterility*  
 4 15 *The Aschheim-Zondek Pregnancy Test*  
 4 30 *Athetosis*

This program is subject to change without notice. The times given are approximate

### SCIENTIFIC EXHIBITS

- Main Auditorium, Worcester Memorial Auditorium
- Booth
- Cutaneous Manifestations of Syphilis* American Medical Association A & B
- Medical Education* American Medical Association C
- Patent Medicines and Quackery* American Medical Association D & E
- A M A Council on Pharmacy and Chemistry* American Medical Association F
- A M A Council on Physical Therapy* American Medical Association G
- A M A Council on Foods* American Medical Association H
- Transurethral Resection of the Prostate and Roentgen Visualization of the Prostate and Urethra.* Drs Fletcher H Colby and Howard I Suby, Urological Service, Massachusetts General Hospital, Boston I
- Cancer* Pondville Hospital, Massachusetts Department of Public Health J
- The Background of Scientific Milk Production* Medical milk commissions of Boston, Worcester and Springfield K
- Fractures* Dr Gordon M Morrison, Boston L
- Cancer Teaching Exhibit* Boston Dispensary, New England Medical Center M & N
- Division of Child Hygiene* Massachusetts Department of Public Health O
- Services for Crippled Children* Massachusetts Department of Public Health P
- Dermatitis Artefacta and Dermatitis Factitia* Dr John G Downing, Boston Q
- Observations on the Effect of Insulin in Nondiabetic Malnutrition* Dr Harry Blotner, Medical Clinic of the Peter Bent Brigham Hospital, Boston R
- Roentgenological and Pathological Studies of Pulmonary Conditions* Rutland State Sanatorium, Rutland S
- Research in Mental Disease* Cardiotachometer and encephalogram Worcester State Hospital, Massachusetts Department of Mental Health T
- Urinary Pathology* Drs. Lester M. Felton, Walter D Bieberbach, Bancroft C Wheeler and Francis J Steele, Worcester U
- Lumbosacral Pathologic Lesions as Causes of Sciatica* Dr Charles E. Ayers, Worcester V
- Blind Nailing of Fractured Hips* Drs John W O'Meara, James A. Givan and Charles V King, Worcester W
- Bilateral Fractures of the Femur* Orthopedic Service, Worcester City Hospital X

### COMMERCIAL EXHIBITS

- Main Auditorium, Worcester Memorial Auditorium
- Booth No
- 1 Ernst Bischoff Company, Incorporated, Ivoryton, Connecticut.

In our exhibit we shall feature Activin, the first American produced shockless foreign protein for non-specific therapy, Alpha Lobelin, a direct stimulant to the respiratory tract and the resuscitant indicated in all forms of respiratory failure or depression, Dia-tussin, the original drop-dose cough remedy with a thirty five year record of efficacy, Silvogon, an absolutely stainless silver antiseptic, an effective gonocide, Styptysate, a vegetable hemostatic for the control of all seeping hemorrhages, Viscysate, a dialysate of viscum album which lowers blood pressure and relieves the accompanying symptoms

- 2 Philip Morris and Company, Limited, Incorporated, New York City

Philip Morris and Company will demonstrate the method by which it was found that Philip Morris Cigarettes, in which diethylene glycol is used as the hygroscopic agent, are less irritating than other cigarettes. Its representative will be happy to discuss researches on this subject, and problems on the physiological effects of smoking

- 3 Hynson, Westcott and Dunning, Incorporated, Baltimore, Maryland.

Hynson, Westcott and Dunning will have an exhibit featuring Mercurochrome and various pharmaceutical specialties of their manufacture. There will also be a display of some of the diagnostic apparatus and ampule solutions which have been developed in co-operation with physicians. As usual, competent representatives of the company will be in attendance to demonstrate the products and to answer questions. Literature and samples will be available to physicians who are not already familiar with products exhibited or who wish to obtain a trial supply

- 4 Moore and Company, Incorporated, Worcester, Massachusetts

Moore and Company will display pharmaceutical preparations and specialties all of which are guaranteed to be true to label and conform to the requirements of the federal and state laws pertaining to the standards and purity of drugs.

- 5 Campbell X Ray Corporation, Boston

Campbell X Ray Corporation will exhibit new methods of shock proofing X ray apparatus

- 6 The E. L. Patch Company, Stoneham, Massachusetts

The Patch Company representatives will be on hand throughout the meeting to greet physicians and to be of service in any way. The Patch Company exhibit will include Patch's Cod Liver Oil, as well as the other ethical medicinal specialties made in the Patch Laboratory

- 7 Kanef Drug Company, Worcester, Massachusetts

The Kanef Drug Company will exhibit pharmaceutical and biological products manufactured by Abbott Laboratories, Lederle Laboratories, Incorporated, Sharp and Dohme, and Winthrop Chemical Company, Incorporated.

- 8-9 The P. L. Rider Company, Worcester, Massachusetts.

The P. L. Rider Company will display a complete line of physicians office equipment, surgical instru-

ments, diagnostic instruments and specialties, as well as trusses, sacroiliac and abdominal supports, stockings, suction and pressure pumps, and electrical centrifuges

- 10 Eli Lilly and Company, Indianapolis, Indiana

Eli Lilly and Company feature an eight foot exhibit stressing the importance of liver extract in the treatment of pernicious anemia, Merthiolate (sodium ethyl mercuri thiosalicylate, Lilly) in the surgical and germicidal fields, Sodium Amytal (sodium iso-amyl ethyl barbiturate, Lilly) in the field of hypnosis, and Iletin (insulin, Lilly) in the management of diabetes mellitus. This is the first appearance of the Lilly Research Laboratories at the meetings of the Massachusetts Medical Society, the exhibit unit has been specially designed for state medical meetings.

- 11 Jones Metabolism Equipment Company, New York City

The Jones Metabolism Equipment Company presents the most modern metabolism apparatus on the market. The Jones Motor-Basal eliminates corrections for barometric pressure and room temperature, and eliminates calculations. It is so simple that anyone can learn to run it in a short time and yet is accurate enough to meet the most exacting requirements of research laboratories. An exclusive geometric device checks the accuracy of each test, thus eliminating the possible error caused by the human element. The Jones Motor-Basal is guaranteed to perform with an accuracy greater than 99 per cent for the lifetime of the purchaser

- 12 Davies, Rose and Company, Limited, Boston.

Members of the Massachusetts Medical Society are so well acquainted with the products of the laboratory of Davies, Rose and Company that no further explanation of their merits is really necessary. However, the company trusts that you will visit its booth and give its representatives the honor of greeting you. Messrs Mansfield and Fleming will be in attendance.

- 13 Baby's Dy Dee Service, Incorporated, Brookline, Massachusetts.

This exhibit explains in detail the specialized equipment and methods used in sterilizing and supplying diapers to homes in Greater Boston. Starting its sixth year, this service has relieved hundreds of mothers and nurses of the daily drudgery of washing diapers and baby clothes, at the same time protecting baby's health by scientific methods impossible at home. An economical service, devoted exclusively to the baby.

Represented by Mary Eustus Sturgis and Faye Reynolds Rand.

- 14-15 John Wyeth and Brother, Incorporated, Philadelphia

John Wyeth and Brother will display the following pharmaceutical specialties from their list of products: kaomagma, an intestinal adsorbent particularly useful in checking diarrhea, Amphojel, Wyeth's aluminum hydroxide for the treatment of gastric hyperacidity and peptic ulcers, Silver Picrate Wyeth, used in the treatment of trichomonas vaginitis, Bewon Elivir, a palatable form of crystalline vitamin B<sub>1</sub>, Mucara a processed form of karaya gum used for

habitual constipation, and other products of general interest to practitioners and specialists

- 16 M and R Dietetic Laboratories, Incorporated, Columbus, Ohio

M and R Dietetic Laboratories will display Similac, a completely modified milk for infants deprived of breast feeding. Representatives will gladly explain its merit and suggested application.

- 17 E R Squibb and Sons, New York City

Physicians are cordially invited to visit the Squibb Exhibit. The complete line of Squibb vitamin, glandular, arsenical and biological products and specialties, as well as a number of interesting new items will be featured. Well informed Squibb representatives will be on hand to welcome you and to furnish any information desired on the products displayed.

- 18 Lea and Febiger, Philadelphia

Among the new books which Lea and Febiger will exhibit, in charge of Mr Paul Loveday, are Stimson's *Fractures and Dislocations*, Haden's *Hematology*, Miller's *Applied Anatomy*, Cowan's *Refraction of the Eye*, Schlanser's *Practical Otology, Rhinology and Laryngology*, Thorndike's *Athletic Injuries* and Brenner's *Pediatric Surgery*. New editions will be shown of MacKee's *X Ray Therapy*, Pohle's *Clinical Roentgen Therapy*, Pohle's *Theoretical Principles of Roentgen Therapy*, Crotti's *Diseases of the Thyroid Parathyroids and Thymus*, Kovacs's *Electrotherapy and Light Therapy*, Ballenger's *Nose Throat and Ear*, Ivy and Curtis's *Fractures of the Jaw*, Brown's *The Surgery of Oral and Facial Diseases and Malformations* and Kanaval's *Infections of the Hand*.

- 19 H J Heinz Company, Pittsburgh.

Heinz Junior Foods, a new variety for older babies, are on display. The Heinz representative is ready to assist you to inspect this new product, as well as the Heinz Strained Foods, also on display. Register at the Heinz booth for helpful literature.

- 20 Mellin's Food Company, Boston

Opportunity will be offered for a discussion of the application of Mellin's Food in the feeding of infants whose individual condition sets them apart from so-called normal babies, and whose diet needs to be adjusted in a manner calculated to correct their digestive disturbance. Mellin's Food is worthy of attention for it has occupied an outstanding position in the field of pediatrics ever since the beginning of the study of the art and science of infant feeding.

- 21 The Borden Company, New York City

Full information on Biolac, the new liquid modified milk for infants, will be available at the Borden booth. Also exhibited will be other Borden products for infant feeding, notably Klim, Dryco, Beta Lactose, Merrell-Soule products and Borden's Silver Cow Evaporated Milk.

- 22 Crosbie-Macdonald, Boston

We represent the United States Fidelity and Guaranty Company, writing physician's liability insurance for members of the Massachusetts Medical Society. Either George H. Crosbie, Edward J. O'Neil, Jr., or

Arthur H. Crosbie will be on hand at all times to discuss any questions pertaining to insurance and to quote rates for your specialty. We are notaries public, and should be glad to sign and file your narcotic drug blanks.

- 23-24 Pet Milk Company, Saint Louis, Missouri.

An actual working model of a milk-condensing plant in miniature will be exhibited by the Pet Milk Company. This exhibit offers an opportunity to obtain information about the production of Irradiated Pet Milk and its uses in infant feeding and general dietary practice. Miniature Pet Milk cans will be given to each physician who visits the Pet Milk booths. Our representatives, Mr. D. O. Tracy and Mr. G. F. Whalen, will be in charge of the exhibit.

- 25 Tailby-Nason Company, Boston.

Tailby-Nason Company has reserved space for the exhibit of Nason's Palatable Cod Liver Oil, made in the company's own plants in the Lofoten Islands of Norway, romantic Land of the Midnight Sun.

More and more leading physicians are relying on good cod liver oil in all cases requiring vitamins A and D. Nason's Oil is prescribed and recommended by leading pediatricians from the Atlantic to the Pacific for its high vitamin potency and unusual palatability.

- 26 S.M.A. Corporation, Cleveland, Ohio

This interesting new display represents the selection of infant feeding and vitamin products of the S.M.A. Corporation. Physicians who visit this exhibit may obtain complete information, as well as samples, of S.M.A. powder and special milk preparations—Protein S.M.A. (Acidulated), Alerdex and Hypo-Allergic Milk.

- 27 The Arlington Chemical Company, Yonkers, New York.

Again The Arlington Chemical Company will feature its biological and pharmaceutical products. They are offering a \$9.75 diagnostic protein outfit, consisting of eighty of the commonest causative factors in allergic conditions, also a full line of food and fungus proteins and pollen extracts for diagnosis and desensitization. The representative in charge of the exhibit will be glad to discuss any allergic problem.

- 28 Smith, Kline and French Laboratories, Philadelphia.

Smith, Kline and French Laboratories, believing that many physicians dislike efforts to make them register, have arranged their booth for self-service. Information about Benzedrine Inhaler, Benzedrine Sulfate Tablets, Benzedrine Solution, Pentnucleotide, Feosol Tablets, Feosol Elixir, Oxo-ate B Tablets and Eskay's Neuro Phosphates may be obtained from the convenient literature dispenser. If additional information is desired, the representative will be glad to answer any questions.

- 29 J. Sklar Manufacturing Company, Brooklyn, New York

The Sklar Manufacturing Company exhibit will feature new suction and pressure apparatus, including the improved Tompkins portable rotary compressor, the de luxe Tompkins, the new Imperator apparatus.

for ear, nose and throat work, the Ralks Ideal Unit and the Moorhead unit for office and clinic, and the new, improved heavy-duty hospital model of the Bellevue suction and pressure unit. The Sklar Company will also exhibit its extensive line of American made stainless-steel surgical instruments, as well as special apparatus, such as the Davidson pneumothorax apparatus, the Sorest blood transfuser, and so forth

### 30 The Macmillan Company, New York City

You are cordially invited to visit the exhibit of the Macmillan Company. On display at this booth you will find two outstanding new medical books, which the Macmillan representative will be glad to discuss with you. One is *The Experimental and Clinical Use of Sulphanilamide Sulphapyridine and Allied Compounds* by Perrin H. Long, M.D., and Eleanor A. Bliss, Sc.D. The timeliness of the subject and the unquestionable authority of the authors should give this book an immediate claim to your attention. The other is *Otolaryngology in General Practice* by Lyman Richards, M.D. An examination of the books with their unique arrangement and fine illustrations will impress you with their practical helpfulness.

Also on display will be the new fifth edition of Dr Hans Zinsser's *Resistance to Infectious Diseases* now significantly entitled *Immunity Principles and application in medicine and public health* and written in collaboration with John F. Enders, Ph.D., and LeRoy D. Fothergill, M.D.

### 31 J. B. Lippincott Company, Philadelphia

Among the newer Lippincott publications on display are the phenomenally successful Thorek's *Modern Surgical Technique* and Kracke's *Diseases of the Blood and Atlas of Hematology* from which illustrations are being displayed at the World's Fair Medical Exhibit. Other important new works include Rigler's *Outline of Roentgen Diagnosis*, Barborak's *Treatment by Diet* and Imperatori's *Diseases of the Nose and Throat*.

### 32 The Alkalol Company, Taunton, Massachusetts

The Alkalol Company will exhibit two preparations: Alkalol, a carefully balanced solution of alkaline and saline salts and essential oils, which is especially prepared for use on mucous membranes or on inflamed or irritated tissues, and Irrigol, a powder which makes an alkaline, saline, non-toxic solution and is valuable for vaginal douches, rectal enemas or colonic irrigations.

### 33 Frederick Stearns and Company, Detroit, Michigan

Frederick Stearns and Company will exhibit their Neo-Synephrin products: Mucilose, Trimax, Apple Powder and Gastric Mucin and will feature their newly developed product—Solution Zinc Insulin Crystals Stearns. Mr. J. P. Burfeind will be in charge.

### 34 Parke Davis and Company, Detroit, Michigan

Members of the staff of Parke Davis and Company will be at your service to tell you about some of their research staff's numerous scientific accomplishments: Mapharsen, Adrenalin, Pitocin, Pitressin. Theelin. Theelol and biological products will be a part of this attractive exhibit.

### 35 Petrolagar Laboratories Incorporated, Chicago

Petrolagar Laboratories offer, in addition to samples of the five types of Petrolagar, an interesting selection

of descriptive literature and anatomical charts. Ask the Petrolagar representative, Mr. E. M. Tarplin or Mr. G. E. Schneider, to show you the new *Habit Time* booklet. It's a welcome aid for teaching bowel regularity to your patients.

### 36 General Electric X-Ray Corporation, Boston.

The General Electric X-Ray Corporation will exhibit a miniature model darkroom, an electrocardiograph and a portable x-ray machine.

### 37 White Laboratories, Incorporated, Newark, New Jersey

The White Laboratories will present information covering the entire field of cod liver oil concentration, together with clinical data and evidence concerning the therapeutic efficacy of its Cod Liver Oil Concentrate, in liquid, tablet and capsule form. Informed representatives and descriptive literature, reprints and excerpts will further demonstrate cod liver oil efficacy, and point out the contributions of White Laboratories in the vitamin A and vitamin D field.

White Laboratories is the world's largest manufacturer of cod liver oil concentrates and is one of the largest users of cod liver oil for pharmaceutical purposes in the world. All physicians are cordially invited to visit the booth.

### 38 Westinghouse X-Ray Company, Incorporated, Long Island City, New York

The Westinghouse X-Ray Company will exhibit several new diagnostic x-ray items that will be of interest to all who are doing x-ray work. There will be shown for the first time an automatic head clamp which was originally developed at Temple University and has proved to be of great value to radiologists and therapists.

### 39 American Hospital Supply Corporation, Chicago

The new simple Baxter blood transfusion set will be shown. See the Baxter Vacoliter, the same intravenous solution used exclusively by many teaching institutions and by over half of all American hospitals. Investigate Coli-Bactragen, it *does* prevent peritonitis. Let us demonstrate the Oxygenaire and the Tomac oxygen insufflator. Look over the automatic apparatus for continuous Wangenstein suction. *Don't miss this booth!*

### 40 Lee De Forest Laboratories, represented by the New England X-Ray Corporation, Boston.

Lee De Forest Laboratories will demonstrate the ultimate in radiotherapy and radiosurgery, designed and built by radio scientists and engineers. Mr. George Laben will be in charge of the exhibit.

### 41 Mead, Johnson and Company, Evansville, Indiana

Three new Mead products are on display at Mead Johnson and Company's booth: Mead's Thiamin Chloride Tablets, Mead's Cevitamic Acid Tablets, Mead's Nicotinic Acid Tablets. Olac for feeding premature babies is also shown, as well as the complete line of Mead's infant-diet materials.

### 42 Lederle Laboratories Incorporated, New York City

Lederle Laboratories will exhibit a full line of biologicals and pharmaceutical specialties featuring the new drug sulfapyridine.

- 43 Winthrop Chemical Company, Incorporated, New York City

The Winthrop Chemical Company extends a cordial invitation to every member of the Massachusetts Medical Society to visit its booth where representatives will gladly discuss the latest preparations made available by this firm. You will receive valuable booklets dealing with anesthetics, analgesics, anturachitics, antispasmodics, antisyphilitics, diagnostics, diuretics, hypnotics, sedatives and vasodilators.

- 44 Surgeons' and Physicians' Supply Company, Boston

The Surgeons' and Physicians' Supply Company will exhibit the new Complex short-wave apparatus, with cable, and other new and interesting items, both in the line of instruments and in that of general supplies.

- 45 Riedel-de Haen, Incorporated, New York City

Riedel-de Haen, the pioneers in bile acid research, will feature the bile acid products, Decholin, Decholin Sodium and Degalol. The hypnotics Pernoston and Pernoston Sodium will also be shown, as well as Sigmodal, the soporific for rectal administration in obstetrics and surgery.

- 46 Gerber Products Company, Fremont, Michigan

The new Gerber Cereal Food, dry, pre-cooked, will be shown to you at the Gerber booth. Samples and professional literature about this cereal product, as well as the other Gerber baby foods, will be available to you.

- 47 Picker X-Ray Corporation, Boston

To the roentgen profession the name of Picker-Waite has always been synonymous with progress. The first successful shockproof x-ray apparatus ever built was of Waite invention. Production facilities plus the combined resources of the Picker-Waite organization, with an electrical and mechanical engineering background of over fifty nine years, have made it possible to produce x-ray equipment at a modest cost.

One of the most outstanding pieces of Picker-Waite equipment is the Picker-Waite Century (100 milliamperes—100 kilovolts), which has been presented to the medical profession as a truly modern diagnostic x-ray apparatus—introducing for the first time an entirely new principle of flexibility in radiographic-fluoroscopic x-ray design and development. Point for point and dollar for dollar the Picker-Waite Century is easily the most outstanding value in diagnostic x-ray equipment offered to a discriminating clientele. We are proud to exhibit this unit with many new and outstanding smaller accessory devices at the meeting of the Massachusetts Medical Society. Bulletins and descriptive literature may be obtained at our booth.

- 48 Horlick's Malted Milk Corporation, Racine, Wisconsin

Nourishing, digestible, appetizing—these are the three outstanding qualities for which Horlick's Malted Milk is famous, whether in powder or tablet form. Visit the exhibit. You will be interested in the many uses from infant feeding to old age, note especially the convenience of the tablets in ulcer diets.

- 49 50 Brewer and Company, Incorporated, Worcester, Massachusetts

Thesodate (Brewer) will be featured at the booth of Brewer and Company. Since the introduction of this product one year ago, it has become the xanthine of choice with many physicians. For information and a liberal supply for clinical trial, register at the Brewer booth.

- 51 G. D. Searle and Company, Chicago.

Products of research, originated in the Searle laboratories, will be the feature of the exhibit of G. D. Searle and Company. Particularly interesting are the recent work on the bile acids and information on the use of Aminophyllin-Searle, as well as the display of Bis-muth Sodium Tartrate-Searle.

52. Hanovia Chemical and Manufacturing Company, Newark, New Jersey

While at the convention do not fail to call at the Hanovia booth. There will be a complete line of the most modern equipment, consisting of ultraviolet quartz lamps with special treatment control, short wave heat generators, Sollux radiant heat lamps and Safe T Air ultraviolet lamps for air sanitation. Courteous and competent representatives will be on hand to welcome you.

- 53 Bilhuber-Knoll Corporation, Jersey City, New Jersey

New reports on the fine medicinals of the Bilhuber-Knoll Corporation are always of interest. Its products include Dilaudid Hydrochloride, an opiate for pain and cough, the well tolerated purine salts, Theocalan and Phyllicin, so useful in the treatment of heart diseases, the cardiorespiratory restorative, Metrazol, of value as an antidote to depressant drugs, for denarcotization after anesthesia, and in the emergencies of heart failure, and the non-barbiturate sedative and hypnotic, Bromural.

Well informed representatives will be in attendance to discuss the new reports with interested physicians.

- 54 The Liebel Flarsheim Company, Cincinnati, Ohio

The Liebel Flarsheim Company will exhibit a complete line of the well known L-F short wave generators, as well as the famous Bovie electrosurgical units. In addition, other new and useful physiotherapy apparatus will be shown. A cordial invitation is extended to visit the Liebel Flarsheim booth in order to inspect this new apparatus and have it demonstrated to you.

- 55 Sandoz Chemical Works, Incorporated, New York City

The Sandoz Chemical Works will feature the following preparations: Gynergen (ergotamine tartrate) for the dramatic relief of migraine, Calglucon (calcium gluconate) granules, effervescent tablets and chocolate flavored tablets, Neo-Calglucon, a new highly water soluble derivative of calcium gluconate, for parenteral calcium therapy, the three reliable bella donna products, Bellafoline, Belladonal and Bellergal, Calcibronat, an organic combination of calcium and bromine, Quinine-Calcium, Sandoz, Scillaren and Scillaren B, the cardioactive principle of squill (*Urginea maritima*), Digilanid, the crystallized initial glucosides of *Digitalis lanata*. Basergin, a stable preparation of pure ergonovine, Neo-Gynergen, a combination of ergotamine and ergonovine for obstetric and gynecological use.

## 56-57 E. F. Mahady Company, Boston

The exhibit of the E. F. Mahady Company includes the latest developments in physical therapy equipment manufactured by the Burdick Corporation, as well as Cutter's intravenous solutions in Safufask dispensers, new surgical instruments and medical books

## 58 The C B Fleet Company, Incorporated, Lynchburg Virginia.

Phospho-Soda (Fleet) is a highly concentrated and purified, aqueous solution of sodium phosphates. It is non toxic, rapid and mild in action without irritation of the gastric or intestinal mucosa. It is indicated for hepatic dysfunction, and for its thorough eliminating and cleansing action on the upper and lower intestines. The C B Fleet Company thanks the medical profession for the broader usage now being given to Phospho-Soda (Fleet). Its prompt, acceptable and controllable action makes it an exceptionally efficient laxative saline and cholagogue.

Mr R. S. Carman will again extend our courtesies

## 59 The Medical Protective Company, Wheaton, Illinois

The most exacting requirements of adequate liability protection are those of the professional liability field. The Medical Protective Company, specialists in providing protection for professional men, invites you to confer, at its exhibit, with the representative there. He is thoroughly trained in professional liability under writing

## 60 The Coca-Cola Company, Atlanta, Georgia.

The Coca-Cola Company in serving complimentary Coca-Cola at its booth hopes that "The Pause That Refreshes" will be enjoyed by guests and visitors of the meeting.

## 61 Kalak Water Company of New York, Incorporated, New York City

Visit the exhibit of the Kalak Water Company and test for yourself the palatability of this delicious, sparkling, neutralizing agent when served properly cooled. Kalak Water has been used by the profession for almost a quarter of a century to re-establish and maintain the alkali reserve and also to supply fluid to patients without producing overloading of the circulation. Because Kalak presents a proper balance of buffer salts, such as the bicarbonates of sodium, calcium and magnesium, it is ideally suited for use in buffering the untoward effects of sulfanilamide or sulfapyridine. Ask the Kalak representative for literature covering the buffering value of Kalak. It is important to remember that Kalak Water is not a laxative.

## 62 Jetter and Scheerer Products, Incorporated, New York City

The world famous line of Jetter and Scheerer surgical instruments will be exhibited again this year. A large variety of both rustless-steel and chrome plated instruments will be displayed, including many unusual and special items. The Jetter and Scheerer line has been held in highest esteem by surgeons since 1867 and is still considered to be the standard for which all others aim. You are cordially invited to visit our booth.

## 63 Sharp and Dohme, Incorporated, Philadelphia.

Sharp and Dohme will feature their well known Propadrine Hydrochloride products. There will also be on display a group of pharmaceutical specialties and biologicals prepared by this house. Capable, well-informed representatives will be on hand to welcome physicians and furnish information on Sharp and Dohme products.

## 64 Abbott Laboratories, North Chicago, Illinois

A hearty welcome awaits you in the Abbott booth where a comprehensive assortment of Abbott specialties is on display. Abbott trained representatives will be glad to answer questions and to discuss their newer products with you.

## BOSTON UNIVERSITY SCHOOL OF MEDICINE ALUMNI ASSOCIATION

A meeting and luncheon of the Boston University School of Medicine Alumni Association will be held at 12:30 p. m., Tuesday, June 6, at the Hotel Bancroft. The charge for the luncheon will be \$1.00.

## HARVARD MEDICAL ALUMNI ASSOCIATION

The annual meeting and luncheon of the Harvard Medical Alumni Association will be held at 12:30 p. m., Tuesday, June 6, at the Hotel Bancroft. The charge for the luncheon will be \$1.00.

## MASSACHUSETTS MEDICO-LEGAL SOCIETY

A meeting of the Massachusetts Medico-Legal Society will be held at 2:00 p. m., Wednesday, June 7, in the Female Chorus Room, Second Floor, Worcester Memorial Auditorium.

## TUFTS COLLEGE MEDICAL SCHOOL ALUMNI

The annual luncheon of the Tufts College Medical School Alumni Association will be held at 12:00 noon, Tuesday, June 6, on the Stage of the Worcester Memorial Auditorium. Members and guests are invited.

## SECTION OF OBSTETRICS AND GYNECOLOGY\*

RAYMOND S. TITUS, M.D., *Secretary*  
330 Dartmouth Street  
Boston

## BLEEDING IN THE PUERPERIUM

Mrs. A. K., a thirty-two-year-old gravida I, was delivered by low forceps on March 30, 1934.

The family history was non-contributory. The patient had had pneumonia as a child. She had never undergone an operation. Catamenia began at thirteen, were regular with a twenty-eight-day cycle, and lasted three to five days without pain.

A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

- 43 Winthrop Chemical Company, Incorporated, New York City

The Winthrop Chemical Company extends a cordial invitation to every member of the Massachusetts Medical Society to visit its booth where representatives will gladly discuss the latest preparations made available by this firm. You will receive valuable booklets dealing with anesthetics, analgesics, antirachitics, antispasmodics, antisyphilitics, diagnostics, diuretics, hypnotics, sedatives and vasodilators.

- 44 Surgeons' and Physicians' Supply Company, Boston

The Surgeons' and Physicians' Supply Company will exhibit the new Comprex short wave apparatus, with cable, and other new and interesting items, both in the line of instruments and in that of general supplies.

- 45 Riedel-de Haen, Incorporated, New York City

Riedel-de Haen, the pioneers in bile-acid research, will feature the bile-acid products, Decholin, Decholin Sodium and Degalol. The hypnotics Pernoston and Pernoston Sodium will also be shown, as well as Sigmodal, the soporific for rectal administration in obstetrics and surgery.

- 46 Gerber Products Company, Fremont, Michigan

The new Gerber Cereal Food, dry, pre-cooked, will be shown to you at the Gerber booth. Samples and professional literature about this cereal product, as well as the other Gerber baby foods, will be available to you.

- 47 Picker X-Ray Corporation, Boston

To the roentgen profession the name of Picker-Waite has always been synonymous with progress. The first successful shockproof x-ray apparatus ever built was of Waite invention. Production facilities plus the combined resources of the Picker-Waite organization, with an electrical and mechanical engineering background of over fifty nine years, have made it possible to produce x-ray equipment at a modest cost.

One of the most outstanding pieces of Picker-Waite equipment is the Picker-Waite Century (100 milliamperes—100 kilovolts), which has been presented to the medical profession as a truly modern diagnostic x-ray apparatus—introducing for the first time an entirely new principle of flexibility in radiographic-fluoroscopic x-ray design and development. Point for point and dollar for dollar the Picker-Waite Century is easily the most outstanding value in diagnostic x-ray equipment offered to a discriminating clientele. We are proud to exhibit this unit with many new and outstanding smaller accessory devices at the meeting of the Massachusetts Medical Society. Bulletins and descriptive literature may be obtained at our booth.

- 48 Horlick's Malted Milk Corporation, Racine, Wisconsin.

Nourishing, digestible, appetizing—these are the three outstanding qualities for which Horlick's Malted Milk is famous, whether in powder or tablet form. Visit the exhibit. You will be interested in the many uses from infant feeding to old age, note especially the convenience of the tablets in ulcer diets.

- 49 50 Brewer and Company, Incorporated, Worcester, Massachusetts

Thesodate (Brewer) will be featured at the booth of Brewer and Company. Since the introduction of this product one year ago, it has become the main thing of choice with many physicians. For information and a liberal supply for clinical trial, register at the Brewer booth.

- 51 G. D. Searle and Company, Chicago.

Products of research, originated in the Searle laboratories, will be the feature of the exhibit of G. D. Searle and Company. Particularly interesting are the recent work on the bile acids and information on the use of Aminophyllin-Searle, as well as the display of Bismuth Sodium Tartrate-Searle.

- 52 Hanovia Chemical and Manufacturing Company, Newark, New Jersey

While at the convention do not fail to call at the Hanovia booth. There will be a complete line of the most modern equipment, consisting of ultraviolet quartz lamps with special treatment control, short wave heat generators, Sollux radiant heat lamps and Safe T Aire ultraviolet lamps for air sanitation. Courteous and competent representatives will be on hand to welcome you.

- 53 Bilhuber-Knoll Corporation, Jersey City, New Jersey

New reports on the fine medicinals of the Bilhuber-Knoll Corporation are always of interest. Its products include Dilaudid Hydrochloride, an opiate for pain and cough, the well tolerated purine salts, Theocalan and Phyllicin, so useful in the treatment of heart diseases, the cardiorespiratory restorative, Metrazol, of value as an antidote to depressant drugs, for denarcotization after anesthesia, and in the emergencies of heart failure, and the non-barbiturate sedative and hypnotic, Bromural.

Well informed representatives will be in attendance to discuss the new reports with interested physicians.

- 54 The Liebel Flarsheim Company, Cincinnati, Ohio

The Liebel Flarsheim Company will exhibit a complete line of the well known L-F short wave generators, as well as the famous Bovie electrosurgical units. In addition, other new and useful physiotherapy apparatus will be shown. A cordial invitation is extended to visit the Liebel Flarsheim booth in order to inspect this new apparatus and have it demonstrated to you.

- 55 Sandoz Chemical Works, Incorporated, New York City

The Sandoz Chemical Works will feature the following preparations: Gynergen (ergotamine tartrate) for the dramatic relief of migraine, Calglucon (calcium gluconate) granules, effervescent tablets and chocolate flavored tablets, Neo-Calglucon, a new highly water-soluble derivative of calcium gluconate, for parenteral calcium therapy, the three reliable bella donna products, Bellafoline, Belladenal and Bellergal, Calebronat, an organic combination of calcium and bromine, Quinine-Calcium, Sandoz Scillaren and Scillaren B, the cardioactive principle of squill (*Urginea maritima*), Digilanid, the crystallized initial glucosides of *Digitalis lanata*, Basergin, a stable preparation of pure ergonovine, Neo-Gynergen, a combination of ergotamine and ergonovine for obstetric and gynecological use.

these and other sponsors of exhibits in the main exhibition halls may meet members of the medical and allied professions under pleasant circumstances

The medical and public-health exhibit, being both scientific and educational, comprises probably the largest single enterprise of its kind ever undertaken specifically for adult health education. The exhibit is in two sections. A vast Hall of Man, which sets forth in unique fashion essential information on human anatomy and physiology, is under sponsorship of the American Museum of Health, with generous assistance from a number of philanthropic foundations and public spirited life insurance companies and commercial institutions. Adjoining the Hall of Man is the Hall of Medical Science and Public Health, an outstanding collection of exhibits on such subjects as tuberculosis, pneumonia, syphilis and maternity and child health.

Local physicians, public health workers and allied professionals will utilize the club to entertain out-of-town guests brought here by the many meetings of national and international groups to be held in New York during the fair. Members of the International Congress of Microbiology meeting in September, 1939, to use one example, may turn to the club not only for information regarding the medical and public-health resources in and about New York City, but for guidance in seeking authoritative local sources of information on the latest developments in technical aspects of their specialized fields.

Management of the club is vested in a board of directors which includes officers of the county medical societies of the five boroughs constituting the City of New York and of adjacent Westchester and Nassau counties. It is a non-profit membership organization, incorporated under the laws of New York State.

## NOTES

Among the fifteen scientists elected to membership at the annual meeting of the National Academy of Scientists were Dr William B. Castle and Dr A. Baird Hastings, of Boston. The former is professor of medicine and the latter Hamilton Kuhn Professor of Biological Chemistry at the Harvard Medical School.

Dr Leroy M. S. Miner, dean of the Harvard Dental School and former president of the American Dental Association, was recently awarded the Jarvie Fellowship Medal by the Dental Society of the State of New York. This medal is presented each year in recognition of outstanding contributions to the dental profession.

## CORRESPONDENCE

### SELECTION OF ORATOR

*To the Editor* I note in the proposed amendments to the by laws of the Massachusetts Medical Society, a suggested change in Chapter IV, Section 3, which limits the selection of the orator for the annual meeting to members of the Council. It is very difficult for me to see any rationale for such limitation. I assume that the society wishes for its annual orator the most effective and capable man for this particular job. It is perfectly reasonable that the most desirable man would usually be a member of the Council, but this does not necessarily follow. For these reasons I should question the desirability of this part of the amendment.

HENRY A. CHRISTIAN, M.D.

721 Huntington Avenue,  
Boston.

## ARTICLES ACCEPTED BY THE AMERICAN MEDICAL ASSOCIATION COUNCIL ON PHARMACY AND CHEMISTRY

*To the Editor* In addition to the articles enumerated in our letter of March 31 the following have been accepted

### Abbott Laboratories

Tablets Barbitol Sodium — Abbott, 5 gr

### Armour Laboratories

Suprarenalin Solution 1:1000 in 1 cc Ampules (for hypodermic use)

Suprarenalin Solution 1:1000 in 10 cc. Vials (for hypodermic use)

Suprarenalin Solution 1:1000 in 1 oz Bottles (for hypodermic use)

### Cutter Laboratories

Ampules Iodobismutol with Saligenin, 2 cc.

### Gane's Chemical Works, Inc.

Racephedrine Hydrochloride

### The National Drug Co

Undulant Fever Vaccine (Abortus and Suis)

Undulant Fever Vaccine (Melitensis)

### Sharp & Dohme

Chicago, Illinois

## REPORTS OF MEETINGS

### HOSPITAL RESEARCH COUNCIL

A meeting of the Hospital Research Council of the Massachusetts General Hospital was held on Tuesday, January 31, in the Ether Dome of the Massachusetts General Hospital, Dr Arthur W. Allen presiding.

The program was opened by Dr Samuel Hertz, who spoke on Radioactive Iodine. Dr Hertz began by describing the method of measurement, using the Geiger counter, to record the amount of radioactivity emanated. The electrons set off a high voltage spark across a gap in a chamber containing air under reduced pressure by ionizing this air. The electrons pass in through a window in the chamber. The electrical discharges are converted into sounds, which can be counted and recorded. The amount of radioactivity in a test substance, then, is in proportion to the number of sounds given off by the counter.

There are five known isotopes of iodine and probably more which have not been identified. These can be made radioactive by subjecting them to bombardment from a

Her last period was August 6, 1933, making her due for delivery early in May

The patient was seen routinely throughout her pregnancy. Her blood pressure never went above 128 systolic, 66 diastolic, and her urine on only one occasion showed a very slight trace of albumin

Ten days after delivery she began to flow very freely. When seen about half an hour after the flowing had started, the pulse was 100, and the blood pressure 100 systolic, 60 diastolic. She looked poorly, but as she was not flowing when seen, the uterus was not invaded. Intravenous glucose was given, and a transfusion postponed. It was believed that the bleeding was due to a piece of placenta which had not been extruded at the time of labor. The next morning her temperature was 101.6°F, having been normal before the bleeding episode. She was passing small pieces of what appeared to be retained placenta. The temperature was normal the following day.

On the next day, April 12, the patient again began to bleed very freely. She was given posterior pituitary extract, ergot and morphine. The blood pressure was 118 systolic, 70 diastolic, and the pulse 100. Under nitrous oxide, oxygen and ether anesthesia a large piece of placenta was found extruding from the cervix. This was removed manually, as were other pieces which were adherent. An alcohol pack was left in the uterus, with the hope that if anything had been left behind it would come away on the pack when removed. The pack was removed the following morning, and because of her anemia,—the hemoglobin was 40 per cent, and the red-blood-cell count 1,280,000,—transfusion was performed, a professional donor being used. Subsequent convalescence was uneventful. On April 14 the hemoglobin was 35 per cent, and the red-blood-cell count 1,090,000, and on April 17, 60 per cent and 2,360,000. There was no further rise in temperature and no more bleeding occurred. She was discharged on April 20.

*Comment.* The treatment of this particular case is open to just criticism. Even though the initial bleeding had ceased when the patient was seen, it was evident that a great deal of blood had been lost. She should have been transfused at that time, and the pieces of tissue removed. This would have prevented the second hemorrhage which resulted in a marked anemia. It must be borne in mind that any patient who bleeds nine or ten days following the birth of a baby does so because of some abnormality inside the uterus. Whether one procrastinates and does not invade the uterus should depend entirely on the amount

of bleeding. If the bleeding is slight, oxytocics may be used successfully, if the bleeding is profuse and no pieces of tissue are observed in the blood which is passed, one must infer that foreign material still remains.

Hemorrhage is the only indication for entering the uterus after delivery, and while one should be conservative about it, one must appreciate that any of these cases may continue to bleed until the uterus is invaded and freed of its foreign material. It is possible in such cases that an accreta is the underlying cause, if so, hysterectomy is the treatment of choice. The majority of delayed hemorrhages, however, are caused by pieces of partially adherent placenta, and these can almost invariably be removed with the fingers or with ovum forceps. Curettage, if employed, should be most delicate, and sharp instrumentation should always be avoided. Transfusion is an extremely important adjunct to intrauterine instrumentation.

## MISCELLANY

### THE PROFESSIONAL CLUB

Physicians, public health workers, medical scientists and other professionals visiting the New York World's Fair 1939 will find reserved for their exclusive use the Professional Club, where members have a place to meet their colleagues in quiet, congenial surroundings.

Unique to this or any other world's fair, the club occupies an area of 5000 square feet on the main floor of the Medical and Public Health Building, which is located on the Theme Plaza, its main entrance being directly opposite the Helicline leading around the Perisphere to the Trylon, where much of importance takes place daily.

The visitor will find awaiting him a comfortable lounge, attractively decorated and furnished, a bar and a snack bar, checking facilities, rest rooms, stenographic service, telephones and other conveniences of a private club.

Membership in the club is limited to accredited members of the medical and public health and allied professions and to representatives of exhibit sponsors. Professional members pay no dues, but there is a small certification charge to cover the cost of validating credentials. Among the organizations whose membership cards entitle their owners to admittance to and use of the club are American Dental Association, American Dental Hygienists Association, American Dietetic Association, American Hospital Association, American Medical Association, American Medical Library Association, American Nurses Association, American Pharmaceutical Association, American Public Health Association, American Veterinary Medical Association, Association of Women in Public Health, Catholic Hospital Association, National League of Nursing Education, National Organization for Public Health Nursing, Pan American Medical Association, Incorporated, United States Department of Agriculture Bureau of Animal Industry, and the United States Public Health Service.

Products of manufacturers sponsoring scientific and educational exhibits in the Medical and Public Health Building are on display in showcases set artistically into the walls of the lounge. The club serves as a place where

these and other sponsors of exhibits in the main exhibition halls may meet members of the medical and allied professions under pleasant circumstances.

The medical and public health exhibit, being both scientific and educational, comprises probably the largest single enterprise of its kind ever undertaken specifically for adult health education. The exhibit is in two sections. ## REPORTS OF MEETINGS

### HOSPITAL RESEARCH COUNCIL

A meeting of the Hospital Research Council of the Massachusetts General Hospital was held on Tuesday, January 31, in the Ether Dome of the Massachusetts General Hospital, Dr. Arthur W. Allen presiding.

The program was opened by Dr. Samuel Hertz, who spoke on Radioactive Iodine. Dr. Hertz began by describing the method of measurement, using the Geiger counter, to record the amount of radioactivity emanated. The electrons set off a high voltage spark across a gap in a chamber containing air under reduced pressure by ionizing this air. The electrons pass in through a window in the chamber. The electrical discharges are converted into sounds which can be counted and recorded. The amount of radioactivity in a test substance, then, is in proportion to the number of sounds given off by the counter.

There are five known isotopes of iodine and probably more which have not been identified. These can be made radioactive by subjecting them to bombardment from a

neutron source. The course of such a radioactivated compound after injection can be traced in its distribution to the various tissues in the body. The experiment consisted of injecting radioactive iodine compounds into rabbits, which had been treated previously with anterior pituitary extract to render the thyroid gland hyperplastic. Fifteen minutes later the rabbits were killed and the various tissues tested with the Geiger counter.

It was found that the thyroid gland contained 38 arbitrary units, whereas the spleen contained only 2, the liver 4, the pituitary gland 0, muscle 0, and the urine 48 (due to the excretion of the iodide). Dr Hertz presented a chart showing the rate of absorption by various types of thyroid gland. The markedly hyperplastic gland is much more able to attract the iodine than is the normal thyroid. After the first fifteen or twenty minutes only a small amount of iodide is further attracted. Dr Hertz suggested that this might prove to have applications of distinct value in estimating thyroid disorders.

This work was undertaken in collaboration by the Massachusetts Institute of Technology and the Thyroid Clinic of the Massachusetts General Hospital. The discussion further revealed that a good many chemical and biological substances can be made radioactive.

The next paper, on 'Prostigmin,' was presented by Dr Henry R. Viets. Dr Viets reviewed the history of myasthenia gravis. It is a very rare disease, the first case at the Massachusetts General Hospital having been seen in 1905. From 1905 to 1935, 30 clear-cut cases were recorded. A quarter of these died in the hospital, the fate of the remainder being largely unknown. Many probably died within two to five years after being seen. Since 1935 there have been 44 cases treated at the hospital, and 6 or 10 more outside. This sudden jump in admissions is the result of the discovery of the action of the drug, Prostigmin, in 1934, it relieved the principal symptoms almost immediately.

Textbooks to the contrary, myasthenia gravis is not a disease of young people, it can occur in persons aged sixty or seventy. The disease is as serious as it ever was, but the mortality has been markedly reduced following treatment with Prostigmin. Other drugs are by no means as effective. The disease is characterized by remissions and relapses, the drug tides over the relapses to stages of remission, thus saving lives. Physiological studies are to be carried out in the near future.

Dr Arturo Rosenblueth, in opening the discussion of Dr Viets's paper, reported some work on the physiology of the disease. An important step in the transmission of stimuli from motor nerve to muscle is the release of acetylcholine at the neuromuscular junction. Wherever acetylcholine is thus liberated, there must be an enzyme, esterase, that splits it to form acetic acid and choline, releasing its effect. Prostigmin prevents or stops the action of this esterase. The question is whether myasthenia gravis is due to an amount of acetylcholine below the required threshold or to a disturbance and abnormal production of esterase. Prostigmin, then, either protects the acetylcholine or inhibits the excess production of esterase.

Dr Otto Krayer brought up the question of similarity between myasthenia gravis and curare poisoning and over dosage with the magnesium ion. In reply to Dr Krayer's question about dosage of Prostigmin, Dr Viets stated that he found the minimum effective intramuscular dose to be 4.5 mg, and 120 mg by mouth. The difference in the amounts in the two forms of administration is unexplained.

The third paper was presented by Dr Tracy B. Mallory, "The Development of Emphysema in Chronic Bronchial Asthma." Dr Mallory said that it was first necessary to define emphysema, since clinicians and pathologists have

always differed. He classified emphysema into three types. The first or earliest he called "physiologic emphysema," occurring under exertion, or in asthma during attacks only. The next stage type was "functional emphysema," which is permanent and physiologic. The third was "structural emphysema," characterized by actual anatomic changes in the lung parenchyma: fusion of air sacs, rupture of alveolar walls and diminution of the respiratory surface area.

Dr Mallory analyzed 45 cases that had come to autopsy. Many of these patients had had asthma without emphysema. There were 13 cases demonstrating active organizing pneumonia or the resultant scarification. Thus, patches of lung were contracted to scars and the surrounding alveoli were dilated so that actual lung volume was unchanged. The more severe the process the more likely it is for bullae to develop as alveolar walls break. The primary causes of death in the group of 45 cases included 12 of pneumonia, 13 of paroxysmal attack, 4 of right heart failure and 2 of pulmonary insufficiency. There were 12 cases of asthma with cor pulmonale, but of these only a few had histologic emphysema. Thirteen cases of the 45 had structural emphysema.

Dr Mallory summarized his observations as follows: the relation of emphysema to asthma is overemphasized, but the relation of cor pulmonale to asthma is underrated, the development of emphysema depends more on the pneumonias than it does on pure asthmatic attacks.

The last paper, "Studies of Plasma Volume," was read by Dr Edward Hamlin, Jr. Dr Hamlin limited his discussion to the effect of adrenalin, Nembutal and sympathectomy on plasma volume in the cat. Plasma volume determinations were based on dilution values of a dye. After the initial determination, adrenalin (1:1000) was given intravenously in a dose three times the amount sufficient for minimal afferent stimulation. In the first experiment 8 out of 10 unanesthetized cats showed a 5 per cent increase in plasma volume. On repetition, all 10 showed an increase. This corroborates the results obtained by other investigators, but is of greater value because an anesthetic effect did not enter into the picture. In an attempt to evaluate the anesthetic factor, an experiment was carried out with Nembutal, 0.5 cc. per kilogram given to each of 6 cats. These showed an immediate increase in plasma volume of 10 per cent, following adrenalin there was a relative decrease—relative in the sense that it never reached the value of the initial reading in a non-anesthetized cat.

Sympathectomy gave variable increases in plasma volume. In sympathectomized cats, Nembutal produced a slight increase, and adrenalin then effected a marked decrease. Explanation of the phenomena is difficult, the effects are probably due to the action of adrenalin on the spleen and that of the barbiturate on vasodilatation, the mechanism of the plasma volume shifts being referable to the capillaries and venules.

#### TRUDEAU SOCIETY

A meeting of the Trudeau Society was held Thursday evening, February 2, in the Beth Israel Hospital auditorium, Dr Leon A. Alley presiding. Dr Alley introduced the speaker of the evening, Dr Edgar Mayer, assistant professor of medicine, Cornell University Medical College, whose subject was Diet in the Treatment of Tuberculosis.

Dr Mayer limited his remarks to a consideration of the particular dietary treatment practiced in certain clinics in Vienna and Munich. He had been sent to these clinics

with Dr Muller on a special commission to study the dietary regimen used in 1928 and thereafter

Based on the observation that an acid, ash residue diet promotes better and more rapid healing of wounds than does a neutral or alkaline one, Sauerbruch and Hermannsdorfer attempted to apply these principles to the treatment of tuberculosis. Gerson entered on this investigation and modified the method. The essence of the diet is low salt and high vitamin content. Special equilibrated salts of calcium, magnesium and potassium are given instead of sodium chloride. Fluids are restricted, and cod liver oil given in large amounts. This diet has the drawback of being very tasteless and difficult to institute.

Gerson's method is to restrict protein intake at first and then gradually give more. His essential is a vegetable basis—raw, boiled, steamed, extracted vegetables and an abundance of fruit and vegetable juices. A Hermannsdorfer diet for a 50-kilo man might consist of the following: 90 gm. of protein, 160 gm. of fat and 240 gm. of carbohydrate (40 to 50 calories per kilo of body weight). In addition the patient is given 40 gm. of cod liver oil, and the fluid intake is restricted to 1500 cc. daily. Salt is restricted to 2 or 3 gm. daily, the normal ingestion being about 15 gm. With the equilibrated salt, one must give hydrochloric acid. Meat and eggwhite are restricted.

In 1926, Sauerbruch first published a report of such treatment in pulmonary tuberculosis, but an analysis of this report reveals no suitable controls. In 1928 the series had been increased to 168 tuberculous patients by Hermannsdorfer and Sauerbruch, who reported glowing results. These results did not seem to be corroborated by other workers. In 1930 Dr Mayer tried the treatment at Saranac and was not particularly impressed. In 1932 Hermannsdorfer reported the results on 34 patients, 22 treated and 12 controls. Apparently no profound effect of the diet was demonstrable. Hermannsdorfer claimed that he got no great effect in the exudative type of pulmonary tuberculosis, in the productive type, however, he claimed to have lowered the temperature and to have decreased the amount of sputum. In 1935 further reports were also not convincing on account of poor controls. In summary the dietary treatment of pulmonary tuberculosis seems to have had very rare dramatic results but has not been consistently of benefit. Perhaps a fair trial has not yet been given, certainly not in this country.

In tuberculosis of the bones and joints and in genitourinary tuberculosis the results have been more consistent, although again the controls are not sufficient. Gerson included in his dietary regimen certain 'thrust days, meaning days in which nothing but raw fruits and vegetables and their juices were eaten. This essentially is a high potassium intake. Gerson claims to have obtained marked improvement in his cases, a single significant piece of evidence is that whereas ordinarily a tuberculous joint becomes quite reddened, painful and swollen if massaged, after a thrust period the joint may be so treated with impunity.

Dr Mayer described a few of his own cases in which as a last resort he tried the Gerson diet and apparently got remarkable results. However, he again concluded conservatively that the very few cases with dramatic results do not constitute an average that allows recommendation of the diet treatment *per se*.

Tuberculosis of the skin and mucous membranes presents some interesting features. It had been shown previously by German investigators that after a period of a salt free diet, the daily ingestion of 20 gm. of sodium chloride produced without exception an excessive out break of skin lesions in several types of skin disease, tuberculous and otherwise. This effect proved to be due to

the sodium and not the chloride ion. It was hypothesized that the sodium ion makes the cell membrane more permeable, and hence the cell becomes reactant to stimuli which ordinarily are not effective. From 1928 to 1932, a series of 600 cases of tuberculosis of the skin so treated was reported, with beneficial results. This work has been confirmed. Tuberculosis of the mucous membranes was said to heal in six or eight weeks, lupus-vulgaris nodules began to disappear in from six to ten weeks. One clinic reported 33 cases of lupus vulgaris treated with the Hermannsdorfer diet, including equilibrated calcium, magnesium and potassium salts. By microscopic photography of the capillary and subcapillary plexuses it was shown that the capillaries narrowed and the circulation improved. Identical changes occurred in cases of x ray dermatitis so treated, unless the lesion had gone on beyond telangiectasia to malignancy.

Dr Mayer concluded that there is a relation between water economy and reduced intake of salt. Tissue imbibition promotes an inflammatory reaction, therefore dehydration has the opposite effect. Vitamin-rich foods are a defense against the progress of infection. The effect of high intake of the cations antagonistic to the sodium ion is as yet still in doubt. Clinically, the effect of the Hermannsdorfer and Gerson diets is also still in doubt. Although a few patients with pulmonary tuberculosis have shown favorable results, the beneficial effect is common in tuberculosis of the bones, joints and genitourinary system and commonest in tuberculosis of the skin. The treatment is expensive and very difficult to administer. He added that there is no specific dietary treatment for tuberculosis but that certain diets will nonspecifically aid by producing beneficial vascular, chemical and cell permeability changes.

Dr Leon A. Alley opened the discussion of Dr Mayer's paper. He described an experiment carried out at Lakeville in conjunction with the Forsyth Dental Clinic which proved fairly conclusively that, in patients with extrapulmonary tuberculosis, a high vitamin-C diet decreased the incidence of carious teeth and also promoted an improvement in affected bones and joints.

Dr Mayer answered several questions as to details of his talk by members of the audience. The one significant point brought out was that he offered the Hermannsdorfer or Gerson dietary treatment to his patients only when other accepted measures had failed or could not be carried out. He made a plea for an open mind on this subject.

#### GREATER BOSTON MEDICAL SOCIETY

A meeting of the Greater Boston Medical Society was held in the auditorium of the Beth Israel Hospital on March 7, with Dr Louis M. Freedman presiding. Dr Maxwell Finland, associate in medicine, Harvard Medical School, and assistant physician, Thorndike Memorial Laboratory, Boston City Hospital, was the speaker of the evening, and his subject was 'The Present Status of the Specific Treatment of Pneumococcal Pneumonia and Other Pneumococcal Infections.'

The speaker retraced the rapid strides in treatment brought about in the past ten years, and particularly in the past two or three years. As long ago as 1910, typing of the pneumococcus was carried out, and three fundamentals of therapy in this disease, which still obtain, were postulated at that time—namely, that the antiserum must be type specific, must give a high titer of antibody and must be given early in the course of the disease.

The important advances in the specific therapy of pneumococcal infections since that time have been the stand

neutron source. The course of such a radioactivated compound after injection can be traced in its distribution to the various tissues in the body. The experiment consisted of injecting radioactive iodine compounds into rabbits, which had been treated previously with anterior pituitary extract to render the thyroid gland hyperplastic. Fifteen minutes later the rabbits were killed and the various tissues tested with the Geiger counter.

It was found that the thyroid gland contained 38 arbitrary units, whereas the spleen contained only 2, the liver 4, the pituitary gland 0, muscle 0, and the urine 48 (due to the excretion of the iodide). Dr. Hertz presented a chart showing the rate of absorption by various types of thyroid gland. The markedly hyperplastic gland is much more able to attract the iodine than is the normal thyroid. After the first fifteen or twenty minutes only a small amount of iodide is further attracted. Dr. Hertz suggested that this might prove to have applications of distinct value in estimating thyroid disorders.

This work was undertaken in collaboration by the Massachusetts Institute of Technology and the Thyroid Clinic of the Massachusetts General Hospital. The discussion further revealed that a good many chemical and biological substances can be made radioactive.

The next paper, on "Prostigmin," was presented by Dr. Henry R. Viets. Dr. Viets reviewed the history of myasthenia gravis. It is a very rare disease, the first case at the Massachusetts General Hospital having been seen in 1905. From 1905 to 1935, 30 clear-cut cases were recorded. A quarter of these died in the hospital, the fate of the remainder being largely unknown. Many probably died within two to five years after being seen. Since 1935 there have been 44 cases treated at the hospital, and 6 or 10 more outside. This sudden jump in admissions is the result of the discovery of the action of the drug, Prostigmin, in 1934, it relieved the principal symptoms almost immediately.

Textbooks to the contrary, myasthenia gravis is not a disease of young people, it can occur in persons aged sixty or seventy. The disease is as serious as it ever was, but the mortality has been markedly reduced following treatment with Prostigmin. Other drugs are by no means as effective. The disease is characterized by remissions and relapses, the drug tides over the relapses to stages of remission, thus saving lives. Physiological studies are to be carried out in the near future.

Dr. Arturo Rosenbluth, in opening the discussion of Dr. Viets's paper, reported some work on the physiology of the disease. An important step in the transmission of stimuli from motor nerve to muscle is the release of acetylcholine at the neuromuscular junction. Wherever acetylcholine is thus liberated, there must be an enzyme, esterase, that splits it to form acetic acid and choline, releasing its effect. Prostigmin prevents or stops the action of this esterase. The question is whether myasthenia gravis is due to an amount of acetylcholine below the required threshold or to a disturbance and abnormal production of esterase. Prostigmin, then, either protects the acetylcholine or inhibits the excess production of esterase.

Dr. Otto Krayer brought up the question of similarity between myasthenia gravis and curare poisoning and overdosage with the magnesium ion. In reply to Dr. Krayer's question about dosage of Prostigmin, Dr. Viets stated that he found the minimum effective intramuscular dose to be 4.5 mg., and 120 mg. by mouth. The difference in the amounts in the two forms of administration is unexplained.

The third paper was presented by Dr. Tracy B. Mallory, "The Development of Emphysema in Chronic Bronchial Asthma." Dr. Mallory said that it was first necessary to define emphysema, since clinicians and pathologists have

always differed. He classified emphysema into three types. The first or earliest he called "physiologic emphysema," occurring under exertion, or in asthma during attacks only. The next stage type was "functional emphysema," which is permanent and physiologic. The third was "structural emphysema," characterized by actual anatomic changes in the lung parenchyma: fusion of air sacs, rupture of alveolar walls and diminution of the respiratory surface area.

Dr. Mallory analyzed 45 cases that had come to autopsy. Many of these patients had had asthma without emphysema. There were 13 cases demonstrating active organizing pneumonia or the resultant scarification. Thus, patches of lung were contracted to scars and the surrounding alveoli were dilated so that actual lung volume was unchanged. The more severe the process the more likely it is for bullae to develop as alveolar walls break. The primary causes of death in the group of 45 cases included 12 of pneumonia, 13 of paroxysmal attack, 4 of right heart failure and 2 of pulmonary insufficiency. There were 12 cases of asthma with cor pulmonale, but of these only a few had histologic emphysema. Thirteen cases of the 45 had structural emphysema.

Dr. Mallory summarized his observations as follows: the relation of emphysema to asthma is overemphasized, but the relation of cor pulmonale to asthma is underrated, the development of emphysema depends more on the pneumonias than it does on pure asthmatic attacks.

The last paper, "Studies of Plasma Volume," was read by Dr. Edward Hamlin, Jr. Dr. Hamlin limited his discussion to the effect of adrenalin, Nembutal and sympathectomy on plasma volume in the cat. Plasma volume determinations were based on dilution values of a dye. After the initial determination, adrenalin (1:1000) was given intravenously in a dose three times the amount sufficient for minimal afferent stimulation. In the first experiment 8 out of 10 unanesthetized cats showed a 5 per cent increase in plasma volume. On repetition, all 10 showed an increase. This corroborates the results obtained by other investigators, but is of greater value because an anesthetic effect did not enter into the picture. In an attempt to evaluate the anesthetic factor, an experiment was carried out with Nembutal, 0.5 cc. per kilogram given to each of 6 cats. These showed an immediate increase in plasma volume of 10 per cent, following adrenalin there was a relative decrease—relative in the sense that it never reached the value of the initial reading in a non-anesthetized cat.

Sympathectomy gave variable increases in plasma volume. In sympathectomized cats, Nembutal produced a slight increase, and adrenalin then effected a marked decrease. Explanation of the phenomena is difficult, the effects are probably due to the action of adrenalin on the spleen and that of the barbiturate on vasodilatation, the mechanism of the plasma volume shifts being referable to the capillaries and venules.

#### TRUDEAU SOCIETY

A meeting of the Trudeau Society was held Thursday evening, February 2, in the Beth Israel Hospital auditorium, Dr. Leon A. Alley presiding. Dr. Alley introduced the speaker of the evening, Dr. Edgar Mayer, assistant professor of medicine, Cornell University Medical College, whose subject was "Diet in the Treatment of Tuberculosis."

Dr. Mayer limited his remarks to a consideration of the particular dietary treatment practiced in certain clinics in Vienna and Munich. He had been sent to these clinics

Before the importance of the higher types in the etiology of atypical pneumonias was determined, the specific treatment of pneumococcal infections in children seemed futile, in the face of the remarkably low mortality of lobar pneumonia due to the types common to adults. But, although the replacement of an anatomical classification by an etiologic one has clarified the important place of the higher types of pneumonia in children, Dr. Curnen emphasized the fact that specific treatment is no substitute for good basic supportive handling of young patients. Nevertheless, serum has been tried with gratifying results for the past two years at the Children's Hospital, and the evidence indicates that the course is shortened and the complications decreased. The ease of administration and the fact that mixed infections are favorably treated make chemotherapy a popular form of therapy in serious cases, but statistics are still inconclusive, although they seem to indicate beneficial results.

Dr. William Dameshek reported amazing results in 50 per cent of cases of pneumonia treated with sulfa-pyridine at the Beth Israel Hospital. Indications for its use are a non typable pneumonia, a type in which specific serum is not available or of equivocal value, a very ill patient, and atypical cases where the typing is questionable. Contraindications include nephritis and a falling white-blood-cell count.

## NOTICES

### REMOVALS

HAROLD BOWDITCH, M.D., announces the removal of his office to 44 Harvard Avenue, Brookline. Telephone LONGwood 4995

WILLIAM M. SANTORO, M.D., announces the removal of his office to 1586 Beacon Street, Brookline. Telephone LONGwood 2060

### GREATER BOSTON MEDICAL SOCIETY

The annual dinner meeting of the Greater Boston Medical Society will be held at the University Club, Boston, on Monday, May 22, at 6:30 p. m. Judge Abraham E. Pinanski, of the Superior Court of Massachusetts, will be the speaker.

LOUIS M. FREEDMAN, M.D., *President*  
DAVID B. STEARNS, M.D., *Secretary*

### TRUDEAU SOCIETY

The annual meeting of the Trudeau Society will be held at the Plymouth County Sanatorium, on Thursday, May 25 at 4:00 p. m. Dr. Benjamin Grushkin of Temple University, Philadelphia, will speak on "The Intracutaneous Method for the Determination of Activity in Cases of Pulmonary Tuberculosis." Dr. Lauren V. Ackerman, of Rutland State Sanatorium, will report on a case of chronic cor pulmonale with unusual pathological findings.

There will be election of officers.

MOSES J. STONE, M.D., *Secretary*

### NEW ENGLAND SOCIETY OF PHYSICAL MEDICINE

The annual meeting of the New England Society of Physical Medicine will be held on Wednesday evening, May 24, at the Hotel Kenmore, Boston.

The Council will meet at 6:00, and an informal dinner will be held in the Empire Room at 6:30. The program will begin at 7:45.

#### PROGRAM

Investigation of Certain Problems in Relation to Tissue Heating. Dr. Michael Pi Joan. 1

Dangers and Complications. Dr. Herman A. Osgood.  
Short Wave Therapy in Arthritis and Bursitis. Dr. Heinrich G. Brugsch.

Clinical Evaluation of Short-Wave Therapy. Dr. William D. McFee.

All members of the medical profession are cordially invited to attend.

WILLIAM D. McFEE, M.D., *Secretary*

### FOURTH ANNUAL CONVENTION OF THE NATIONAL GASTROENTEROLOGICAL ASSOCIATION

The fourth annual convention of the National Gastroenterological Association will be held at Squibb Hall, Squibb Building, 745 Fifth Avenue, New York City, on June 1 and 2. A very interesting program is assured.

Members of the medical profession are cordially invited to attend.

HENRY KENDALL, M.D., *Chairman*  
Program Committee.

### AMERICAN CONGRESS OF PHYSICAL THERAPY

The eighteenth annual scientific and clinical session of the American Congress of Physical Therapy will be held on September 5, 6, 7 and 8 at the Hotel Pennsylvania, New York City. Preceding these sessions the Congress will conduct an intensive instruction seminar in physical therapy for physicians and technicians—August 30 and 31 and September 1 and 2.

For information concerning the seminar and the preliminary program of the convention proper, address the American Congress of Physical Therapy, 30 North Michigan Avenue, Chicago.

### SOCIETY MEETINGS AND CONFERENCES

#### CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY, MAY 22

##### MONDAY MAY 22

6:30 p. m. Greater Boston Medical Society. University Club, Boston.

##### TUESDAY MAY 23

9-10 a. m. Hemoglobin, Iron, Bilirubin. Dr. George Barkan. Joseph H. Pratt Diagnostic Hospital.

10 a. m. 12:30 p. m. Tumor clinic. Boston Dispensary.

##### WEDNESDAY MAY 24

9-10 a. m. Hospital case presentation. Dr. S. J. Thannhauser. Joseph H. Pratt Diagnostic Hospital.

12 m. Clinicopathological conference. Children's Hospital amphitheater.

7:45 p. m. New England Society of Physical Medicine. Hotel Kenmore, Boston.

ardization of antisera by exact methods, the concentration of sera so that a similar number of antibodies are available in a small volume, the subdivision of Group IV pneumonias and the manufacture of specific sera for some of these higher types, the introduction of therapeutic rabbit serum, in which a higher titer can be obtained in a shorter time than it can in horse serum, and finally chemotherapy, which, while still in its incipency, appears at least promising.

Dr Finland presented the results obtained at the Boston City Hospital by all methods of treatment in the pneumonia cases admitted during the ten year period 1929-1938. It was emphasized that these statistics were complicated not only by the ever-prevalent difficulty in controlling biological experiments, but also by the inadequate amounts of serum available in the earlier years when only the very sick patients were given specific therapy. In regard to etiology, it was pointed out that 80 per cent of all cases of lobar pneumonia in adults are due to Types 1, 2, 3, 5, 7 and 8, with the first three accounting for almost 60 per cent of the whole. On the other hand, although Types 1, 2 and 5 produce lobar pneumonia predominately, the others more often produce atypical pneumonias and focal infections, particularly Type 3.

There are certain generalities which hold for the treatment of pneumococcal infections of whatever type. Thus, bacteremia increases the mortality rate with or without treatment, although the small number of positive blood cultures in the specifically treated patients probably indicates an abortion or prevention of some such cases. The differences in bacteremic and in non-bacteremic mortality rates, however, vary somewhat among the types. A further factor common to all is the efficacy of early treatment, particularly before the fourth day. Moreover, in all types of pneumonia for which there is a specific serum, there has been some reduction in the mortality under treatment. In all these respects there is a quantitative difference in the various types.

The reduction in mortality by the use of specific horse serum varies from 75 per cent in Type 5 to practically nil in Type 3, although all the common types except the latter show at least a 50 per cent drop of the death rate. The apparent failure of Type 3 serum is explained by the paucity of available material and the necessity of saving it for the very sick patients. Rabbit serum finds its greatest use in Types 2 and 7, where the level of antibody titer often reaches five or six times that of horse serum. Although there seems to be no striking reduction in the incidence of empyema following the use of specific therapy, this may be explained by the fact that those who now live to develop this condition would have died without specific treatment, for more patients with pneumonia now avoid a fatal issue.

Untoward reactions from serum therapy occurred in higher percentage in this series of cases than in comparable groups using commercial products, for many of these incidents took place with sera that were being clinically tested before being released for general consumption. This line of reasoning also holds for the high incidence of reactions following the early use of rabbit serum, which was at least as high as that with horse sera. Indeed, the only severe reactions—that is, collapse—occurred in early experimental work. The common manifestations include nausea, vomiting, urticaria, collapse, chills and joint pains. The usual precautions should be taken: a careful allergic history, slow administration of the serum, and constant vigilance during the initial stages of the injection. Administration should be immediately discon-

tinued on noticing any untoward signs, and adrenalin should be used in severe reactions, if necessary.

The common causes of failure in specific serum therapy are delayed treatment, occasionally due to a misjudgment of the duration of the disease, errors in typing, inadequate or spread dosage, focal purulent infections mixed infections, especially with a streptococcus, and other complicating conditions or diseases, such as pregnancy, nephritis, congestive failure, and so forth.

Dr Finland went on to discuss the intriguing subject of chemotherapy, but without benefit of conclusive statistics as presented for serum therapy. This discussion was based on the use of sulfanilamide during 1937-1938 in a large series at the Boston City Hospital and observations during the present winter on sulfapyridine. The bacteriostatic action of these drugs *in vitro* has been proved satisfactory with many pneumococci but is not so striking as it is against the streptococci. And although the range of effectiveness is still debatable, the speaker said that sulfanilamide has exhibited its lifesaving qualities on several occasions. The most promising results have been obtained in Type 3 pneumonias, where sulfapyridine particularly has been extolled. Many preliminary reports on its use compare favorably with results from serum treatment, but none of these have emanated from a clinic where an adequate base line of results with and without serum has been established. Dr Finland recently reported a group of Type 3 patients treated with serum or sulfanilamide or both and found the results almost identical and seemingly not very striking. However, only the seriously sick patients received sulfanilamide, and since their mortality was at least as low as that of those otherwise treated, some benefit must have resulted from the chemotherapy. These results, together with other clinical reports and *in vitro* experiments, seem to indicate that in certain instances the optimum results are obtained from a combination of chemotherapy and specific serum therapy. One definite advantage of the addition of these bacteriostatic substances to the regimen is the opportunity it affords of discontinuing serum therapy, with its concomitant dangers, somewhat earlier than heretofore. Untoward reactions are not unheard of with these chemicals, however. Those encountered so far include hemolytic anemia, granulocytopenia, nausea and vomiting, nitrogen retention and certain symptoms of the central nervous system, such as profound depression and wild delirium.

In conclusion, Dr Finland stated that specific serum therapy has established its worth, with the possibility of rabbit serum, when available, replacing horse serum, due to its greater efficacy per unit volume and greater ease in preparation. The use of sulfanilamide and sulfapyridine, either alone or in combination with serum, appears to offer a powerful means of therapy, but there have not as yet been a sufficient number of controlled studies to substantiate all the rosy claims.

In discussion, Dr Frederick T. Lord emphasized certain features of the treatment of pneumonia in private practice, especially in regard to serum therapy. Blood culture when the patient is first seen may afford an early and sometimes the only means of typing, besides partly determining the dosage of serum to be given. He finds that, on the whole, too small dosage is given, the administration is too slow, and there is a failure to adjust the dosage to the requirements of the individual case. The nominal amount should be doubled when there is a positive blood culture, when the temperature fails to drop and when there is clinical evidence of a spreading lesion.

Dr Edward Curnen, of the Children's Hospital, discussed certain differences in the pneumonias of children.

## BIOPSY OF THE UTERINE CERVIX\*

The End Results of One Hundred Consecutive Interventions

LOUIS E. PHANEUF, M.D.,† AND MAURICE O. BELSON, M.D.‡

BOSTON

IN THE present state of our knowledge the best results in the management of carcinoma in any part of the human body are obtained through early diagnosis and early application of the best treatment known. This applies emphatically to the uterine cervix, which is readily accessible to palpation and visualization. There are no symptoms in early cancer of the cervix, and this accounts for the fact that the diagnosis in many cases is not made until the disease is well established. The symptoms of the non-malignant diseases of the portio bring a number of patients to the physician. Again, the irritative lesions of this organ, such as lacerations, ectropion, erosion, chronic cervicitis and endocervicitis, are discovered during the course of a periodic health examination. We are beginning to realize that the so-called cancer age is a misnomer, as this disorder may occur at any age. Be that as it may, all clinicians of wide experience know for a certainty that cancer of the cervix is found most frequently in the fourth decade of life. The ideal would be the periodic examination of all women who have reached this age, bearing in mind that the disease, while most commonly found in those who have been subjected to the trauma of labor, may exist in nulliparous and virginal women.

At the Boston Dispensary we see a large number of cervices, showing a varying amount of irritation, some coincidental with the trauma of childbirth, others as the result of inflammatory disease. Five years ago the Department of Gynecology adopted the policy of making one of us (L. E. P.) responsible for the diagnosis and disposition of all pelvic carcinomas. With this end in view, a special

clinic was established to which all such patients, including those with pathologic cervixes, are referred. It is usually impossible to differentiate, with the naked eye, severe chronic cervicitis and early carcinoma. Since the true diagnosis of carcinoma can be established only by the microscope, it is obvious that a biopsy specimen must be obtained. The Schiller test and the colposcope are helpful in selecting the area from which the biopsy should be taken, but they accomplish no more.

The taking of a cervical biopsy is a simple procedure. The area having been selected, the specimen may be excised with a sharp knife, the No. 11 Bard-Parker blade being excellent for this purpose. The base of the incised area is cauterized with *crude carbolic acid*, a 15 per cent solution of iodine or a cautery, if one is available, this is done in order to seal the lymphatics and prevent metastases if carcinoma is present. In a clinic where a large number of biopsies of the cervix are taken, there are advantages in using the electrically charged wire loop of the high-frequency apparatus, since this seals the lymphatics as the tissues are cut through. The charring is not sufficient to interfere with a satisfactory histological examination. The commoner lesions of the cervix, such as simple erosions and small lacerations, are treated by *linear* cauterization with a fine tip cautery. From the more severe lesions most of the tissue under the ectropion or erosion is removed from both the anterior and posterior lips. This procedure serves two purposes: on the one hand it permits a histological diagnosis, and on the other is responsible, in the absence of carcinoma, for healing the organ. In chronic cervicitis treated by this procedure, the cervix is usually completely healed and covered with healthy squamous epithelium in the course of six or at the most eight weeks. In rare cases severe areas may have to be subsequently cauterized. If the diagnosis of carcinoma is established, treatment in the form

lished by the Harvey Cushing Society The compiler and  
the printer have worked together to produce a book of  
exceptional value.

*The Extra Pharmacopoeia* Martindale Twenty-first edi-  
tion Vol 2 1148 pp London The Pharmaceutical  
Press, 1938 22s 6d.

When the production of a book extends through twenty-  
one editions it is fair to assume that there is approval of  
its quality to interest and instruct its readers. In this pub-  
lication, the Council of the Pharmaceutical Society of  
Great Britain presents the advances made in pharmacology  
and the ancillary subjects of medical knowledge.

Beginning with an analytical addendum to the list of  
chemicals and the materia medica set forth in Volume 1  
of this edition, there will be found in subsequent sections  
of this volume a list of the proprietary medicines sold in  
Great Britain with the composition of each, so far as ascer-  
tained, following are chapters on reagents and analyses  
of body fluids, nutrition and vitamins, chemical sub-  
stances used in therapeutics, and bacteriological and clinical  
notes in explanation of an extensive list of diseases,  
with the preventive and therapeutic principles applicable  
to each

The wide range of subjects dealt with requires an ex-  
tensive, carefully and concisely phrased text which con-  
veys useful up-to-date information, for physicians and  
students, relating to the preservation of health and the  
alleviation of human suffering

*Dunant The story of the Red Cross* Martin Gumpert  
323 pp New York Oxford University Press, 1938.  
\$2.50

This is a well written book concerning a strange and  
interesting man. It is more than a biography for the  
author not only gives the facts of Dunant's life but also  
records the history of Europe from 1850 to 1910, the year  
of Dunant's death. After the battle of Solferino in 1859,  
where Dunant first visualized the need for a Red Cross  
in war, one travels with this extraordinary man from  
country to country, watching the growth of the Red Cross  
idea on the background of European political, martial  
and economic upheavals The author has done his  
work well, and the book gives a splendid picture of the  
man and his times Dunant's career as one of the most  
distinguished men of his day, the Nobel prize of 1901,  
his loss of friends and final poverty, and his tragic end in  
1910, are all clearly told The text appears to be well  
translated from the German.

## BOOK REVIEWS

*A Bibliography of the Writings of Harvey Cushing Pre-  
pared on the occasion of his seventieth birthday  
April 8 1939* The Harvey Cushing Society 108 pp  
Springfield, Illinois Charles C Thomas, 1939 \$5.00

This beautifully printed book, complete in every sense,  
is a welcome addition to medical literature and a fitting  
*Festschrift* for one of America's greatest surgeons. It con-  
tains the facts of his life, his degrees, a list of each mono-  
graph and paper by him, as well as those coming from his  
clinic, and a list of his associates. There are six hundred  
and fifty-eight items in all, cited with care and augmented  
with additional notes, giving unusual facts about the ar-  
ticles The book is worthy of the man. There is an ap-  
propriate introduction by Arnold C Klebs A limited  
edition, with special typographical features, has been pub-

*Allergic Diseases Their diagnosis and treatment* Ray M  
Balyeat and Ralph Bowen. Fifth edition. 547 pp  
Philadelphia F A. Davis Co, 1938 \$6.00

A clear conception of allergic manifestations has been a  
much needed chapter in medical knowledge of today  
This need has been met by a perfectly clear, lucid and  
comprehensive text written by Dr Balyeat. The matter  
is comprehensively and systematically organized and pre-  
sents the allergic manifestations of almost every known  
substance. It also explains the errors in the reactions and  
proposes the need of a conservative judgment on the part  
of the physician The plates reproduced in the text,  
however, are particularly poor, being dark and with little  
detail. In spite of this, the book must be highly recom-  
mended to every internist who needs a handbook and text  
for reference to the problem of allergy

## BIOPSY OF THE UTERINE CERVIX\* The End Results of One Hundred Consecutive Interventions LOUIS E. PHANEUF, M.D.,† AND MAURICE O. BELSON, M.D.‡ BOSTON

IN THE present state of our knowledge the best results in the management of carcinoma in any part of the human body are obtained through early diagnosis and early application of the best treatment known. This applies emphatically to the uterine cervix, which is readily accessible to palpation and visualization. There are no symptoms in early cancer of the cervix, and this accounts for the fact that the diagnosis is well established. The symptoms of the non-malignant diseases of the portio bring a number of patients to the physician. Again, the irritative lesions of this organ, such as lacerations, ectropion, erosion, chronic cervicitis and endocervicitis, are discovered during the course of a periodic health examination. We are beginning to realize that the so-called cancer age is a misnomer, as this disorder may occur at any age. Be that as it may, all clinicians of wide experience know for a certainty that cancer of the cervix is found most frequently in the fourth decade of life. The ideal would be the periodic examination of all women who have reached this age, bearing in mind that the disease, while most commonly found in those who have been subjected to the trauma of labor, may exist in nulliparous and virginal women.

At the Boston Dispensary we see a large number of cervixes, showing a varying amount of irritation, some coincidental with the trauma of childbirth, others as the result of inflammatory disease. Five years ago the Department of Gynecology adopted the policy of making one of us (L. E. P.) responsible for the diagnosis and disposition of all pelvic carcinomas. With this end in view, a special clinic was established to which all such patients, including those with pathologic cervixes, are referred. It is usually impossible to differentiate, with the naked eye, severe chronic cervicitis and early carcinoma. Since the true diagnosis of carcinoma can be established only by the microscope, it is obvious that a biopsy specimen must be obtained. The Schiller test and the colposcope are helpful in selecting the area from which the biopsy should be taken, but they accomplish no more.

The taking of a cervical biopsy is a simple procedure. The area having been selected, the speculum may be excised with a sharp knife, the No. 11 Bard-Parker blade being excellent for this purpose. The base of the incised area is cauterized with crude carbolic acid, a 15 per cent solution of iodine or a cautery, if one is available, this is done in order to seal the lymphatics and prevent metastases if carcinoma is present. In a clinic where a large number of biopsies of the cervix are taken, there are advantages in using the electrically charged wire loop of the high-frequency apparatus, since this seals the lymphatics as the tissues are cut through. The charring is not sufficient to interfere with a satisfactory histological examination. The commoner lesions of the cervix, such as simple erosions and small lacerations, are treated by linear cauterization with a fine-tip cautery. From the more severe lesions most of the tissue under the ectropion or erosion is removed from both the anterior and posterior lips. This procedure serves two purposes: on the one hand it permits a histological diagnosis, and on the other it heals the organ. In chronic cervicitis treated by this procedure, the cervix is usually completely healed and covered with healthy squamous epithelium in the course of six or at the most eight weeks. In rare cases severe areas may have to be subsequently cauterized. If the diagnosis of carcinoma is established, treatment in the form

\*From the Gynecological Department of the Boston Dispensary, a unit of the New England Medical Center. Read at the annual meeting of the New England Obstetrical and Gynecological Society, Boston, December 1, 1938.

‡Instructor in gynecology, Tufts College Medical School, assistant surgeon, Department of Gynecology, Boston Dispensary.

of irradiation by means of radium and high-voltage x-ray therapy is immediately applied. A cancer which is so early that it cannot be detected with the naked eye shows good results under this form of therapy. Women with deeply lacerated cervixes who have no evidence of carcinoma on microscopic examination are referred to hospitals for plastic repair or amputation.

This study represents the findings of an analysis of 100 patients treated at the New England Medical Center from September, 1934, to September, 1938, in whom the results of the clinical examination of the cervix were such that biopsy was performed.

The ages of the patients varied from twenty-one to seventy-five. Tabulating the series according to ages in ten-year groups, we found 8 per cent from twenty-one to thirty years, inclusive, 34 per cent from thirty-one to forty, 32 per cent from forty-one to fifty, 16 per cent from fifty-one to sixty, 8 per cent from sixty-one to seventy and 2 per cent from seventy-one to seventy-five. Two thirds of the patients were in the third and fourth decades, the remaining third being distributed over the second, fifth, sixth and seventh.

In this group of 100 women 10 had borne no children, of these only 1 had had any miscarriages, and she had had three. The remaining 90 had each borne from one to twelve children. Forty-six patients, or almost half the total number, had borne either two or three children.

Sixty-nine, or more than two thirds, of the women had had no miscarriages. Of the remaining 31 patients, 14 had had one, 9 two, 5 three and 3 four.

Thirty-four women, a little over one third of the total, were beyond the menopause, of these, 32 had had a natural menopause and 2 a surgical one.

The blood Hinton test was negative in 84 patients, positive in 13, doubtful in 2 and not done in 1. Four of the 13 who had positive reactions also had carcinoma of the cervix. Syphilis and carcinoma may be present at the same time in the same person, and the fact that the patient has a positive Hinton test should not deter one from doing a biopsy of a suspicious lesion of the cervix.

The Schiller test was not done routinely in these cases. Of the 36 patients on whom the test was performed, the reaction was positive in 6, negative in 15, and suspicious in 15. The histological reports of the biopsy in the 6 positive cases indicated chronic cervicitis with erosion, of the 15 suspicious cases, 2 were carcinoma of the cervix and 13 were chronic cervicitis. On histological examination 1 case with a negative reaction proved to be carcinoma.

In this series only 3 women had had some oper-

ative procedure on the cervix previous to the biopsy. 2 had had cauterization of the cervix and 1 trachelorrhaphy.

The clinical diagnoses previous to biopsy were as follows: erosion of the cervix in 68 women, laceration with erosion of the cervix in 21, carcinoma of the cervix in 6, papilloma of the cervix in 1, cervical polyps in 2, carcinoma of the vagina in 2. The microscopic diagnoses are shown in Table 1. Some of the histological reports had

TABLE 1 *Histological Diagnoses*

DIAGNOSIS	NO. OF CASES
Chronic cervicitis	59
Chronic endocervicitis	25
Erosion of cervix	24
Nabothian cysts	5
Ulceration of cervix	1
Cervical polyp	1
Suggestion of malignancy	1
Carcinoma of cervix	5
Epidermoid carcinoma of cervix	2
Squamous-cell carcinoma of cervix	2
Metastasis to cervix (primary in body of uterus)	1
Adenocarcinoma of vagina (primary in body of uterus)	1
Undifferentiated carcinoma (Grade 4)	1
Glandular hyperplasia and metaplasia of surface epithelium	1
Leiomyosarcoma	1
Fibroma of cervix	1
Tuberculosis of cervix	1
Total	132

more than one diagnosis, which accounts for the discrepancy between the number of cases examined (100) and the number of diagnoses (132).

Eighty-two per cent of the patients had histological diagnoses of chronic cervicitis, chronic endocervicitis, erosion, nabothian cysts or ulceration or a combination of these, in 1 per cent the diagnosis was cervical polyp, and in another 1 per cent tuberculosis and in still another 1 per cent, fibroma of the cervix. Ten per cent had a diagnosis of carcinoma of the cervix, and 1 per cent each, metaplasia of the surface epithelium, a suggestion of malignancy, metastasis to the cervix (primary in the body of the uterus), adenocarcinoma of the vagina (primary in the body of the uterus), and leiomyosarcoma. In other words, 85 per cent of these women had benign lesions.

The 10 patients in whom cervical carcinoma was discovered were treated by irradiation with radium and high-voltage x-rays. In all the cervix was healed. The longest time elapsing since treatment was instituted is about four years, so that more time must pass before we can speak in terms of cure or arrest. However, in none of these patients was there parametrial involvement at the start of the therapy, nor has there been any since. It seems fair to assume that a high percentage of these early cases will be cured, all are under observation at the present time.

#### SUMMARY AND CONCLUSIONS

In the state of our present knowledge the best results in the management of carcinoma of the

cervix must come from early diagnosis and early treatment.

The Schiller test and the colposcope are useful methods in pointing out the area from which a biopsy must be taken.

The diagnosis of carcinoma of the cervix can only be established with the microscope.

A biopsy specimen may be taken satisfactorily in ambulatory patients with a sharp knife or the electrically charged wire loop of the high-frequency apparatus. If the former is used, the base of the incised area must be cauterized in order to seal the lymphatics. Usually no anesthesia is required.

Only a biopsy and histological study will settle the diagnosis between severe cervicitis and early carcinoma.

When cancer is not present, removal of the tissue under irritation for a biopsy specimen causes the cervix to heal.

In a series of 100 consecutive biopsies in severely irritated cervixes, primary carcinoma was reported in 10 per cent.

All patients with early cancer of the cervix were treated by means of radium and high-voltage x-rays. In all, the cervixes are healed, and the patients are under observation at the present time.

## GROUP HOSPITALIZATION\*

REGINALD F. CAHALANE†

BOSTON

IN THE midst of all the discussions of the political, social and economic trends of the American way of living, there still dominates in the average, self-supporting individual a desire to plan for meeting his bills, as is evidenced by the rapid growth of membership in hospital service plans. The co-operative movement of the hospitals has enabled this section of the public to budget the low cost of medical protection, and they have thus come to realize the value of this non-profit service. The small cost alone does not necessarily attract public interest. The rapidly increasing popularity of group hospitalization is due to actual performance of the services rendered. This movement is meeting the challenge of a changing economic order by rendering services within the means of the average person, yet on a normal economic basis.

Non-profit hospital protection is motivated by a desire to alleviate the financial burden of unanticipated hospitalization—not with the implication that hospital bills are too high, but because illness or accident may require hospital care at a time when the cost is burdensome.

Plans for hospital care become possible through the co-ordination of three interests: the subscriber, who pools his subscription with fellow-subscribers, the plan, which serves as trustee for these funds, and the hospital, which renders the service. Accordingly the movement is a combination of insurance and public welfare. Its fundamental principle is simplicity of procedure in striving to serve the average person by rendering *all inclusive* hos-

pital services. Such benefits to the subscriber-patient become easily understood as the hospital promptly and efficiently renders these services and the service plan quickly relieves the patient of financial worry through assurance of his ability to pay. The subscriber-patient is served because he has provided for the contingency. Furthermore, the hospital is relieved of the problem of installment collection. It is predicted by the American Hospital Association that there will be two hundred plans and ten million subscribers within the next five years. I believe this prediction will prove to have been most conservative when a full realization of embryonic plans comes to pass.

The primary purpose of group hospitalization is that of public service, and the subject should not be attacked solely from the point of view of benefit to hospitals or the medical profession. While it is recognized that problems of hospital finance originate in the inability of a great many patients to pay the cost of care,—and the same is true of doctors' bills,—any measure to overcome financial difficulties which does not attack the root of the problem falls far short of a satisfactory solution. The only method thus far devised which partially solves this fundamental problem is group hospitalization.

While group hospitalization plans have been in operation for a number of years, the newer ones are still in the early stages of development and the older ones, through their experience, are better able to progress. The rapid advance which is being made can be interpreted as a marked contribution to the welfare of any community enjoying the advantages of group hospitalization. Its public benefits may be far-reaching under proper

\*Presented at the annual meeting of the Vermont State Medical Society, Burlington, October 6, 1935.

†Executive Director, Associated Hospital Service Corporation of Massachusetts.

administration and control. Because its possibilities for good are great, there is considerable likelihood that it may become a source of danger, both to the relations of hospitals with the public and to the obvious advantages of voluntary and ethical control of hospital services. If it is permitted to develop along unethical or commercial lines, the public-service viewpoint may be obscured and become secondary to private or commercial interests. Consequently, the primary concern of group hospitalization as hospital service must be public service, with individual interests of hospitals as institutions secondary to that of the fundamental principle and policy of public benefits. The problem of presenting the benefits of the plan to this group cannot be solved until arrangements are made whereby medical service can be included on a basis which has the approval of the medical profession. This is a problem which the medical profession must solve and one which hospital service plans cannot conquer alone. Benefits as they exist today are of such scope as to embrace a part of the population which has heretofore been overlooked. Group hospitalization offers subscribers the means of maintaining their independence and self-respect, and at the same time enables hospitals to furnish needed services without incurring deficits. The result is improvement in public relations with and good will toward hospitals, the latter of which, while it cannot be measured in dollars and cents, is an asset of tremendous importance to the community and to hospitals generally.

No one will deny or belittle the benefits which have come to thousands of needy individuals and to member hospitals, but since the services rendered by a hospital in a community are in effect a public service, it appears that in communities where there is more than one hospital such hospitals should participate in a plan of this type in order that the public normally served by them may obtain benefits without restriction to a single institution, with all the complications and limitations involved therein. The administration and control of any plan should be vested in a body representing the community, there should be no domination either by hospitals or the medical profession, but both should be adequately represented.

The discerning student of the problem, and of the solution of it offered by group hospitalization, must come to the conclusion that a plan organized, established and operated on a non-profit basis, involving the participation and united action of its member hospitals, offers the best means of protection to hospitals against any unfavorable development of group hospitalization. The acceptance of this theory involves the whole-hearted co-operation

and support on the part of hospitals in the establishment and operation of such plans. Hospitals themselves have an important role to play in the sound administration and operation of any plan, and it is possible that the lack of such whole-hearted co-operation has encouraged the establishment of plans which do not embrace all the protective measures mentioned. There is need of adequate public safeguards against poor and inefficient administration, and such safeguards are undoubtedly found in proper and careful supervision by state departments of insurance, under laws which provide such supervision without burden some taxes or investments.

Every plan must necessarily have the interest and co-operation of the medical profession, and the future is to a large extent in its hands. The medical profession has been helpful, and where opposition has been apparent it has been caused usually by a lack of understanding or because of a conflict between certain members of the medical profession and the hospitals in which they practice. Let us assume that a hospital service plan is properly established on the basis of limiting its benefits to actual hospital service, and that the hospitals agree to render such service. There is no need for capital investment, because the facilities and equipment of member hospitals represent adequate assurance that benefits can and will be provided in accordance with the terms of the subscriber's agreement, and that the agreement will be observed by those in charge of the plan and the member hospitals. In other words, member hospitals themselves become the reserve of any voluntary hospital service plan. Voluntary hospitals are operated as community service organizations on the same basis as that on which hospital service plans should be operated. The only factor of public safeguard that remains necessary is that subscription rates, payments to hospitals and operating costs shall be established and properly maintained so as to ensure financial soundness without loss to any party concerned.

No hospital service plan should attempt to operate until it is able to meet the standards of organization as set forth by the American Hospital Association. This association has ruled that no organization can be approved and its members permitted to use the Blue Cross with the American Hospital Association seal superimposed thereon until it has had at least six months of successful experience. Approval by the association means a great deal to subscribers and to employers who make a plan available to their employees. There are now forty approved plans, and it is expected that this number will increase with the publishing of the next list.

Let us consider briefly some of the standards for non-profit hospital service plans. First, the corporate body should include adequate representation of hospitals, the medical profession and the general public, and board members should receive no remuneration for their services, second, no private investors should advance money in the capacity of stockholders or owners, initial working capital may best be provided by individuals, community chests, hospital councils or other civic agencies. It is my opinion that this money should not take the form of gifts but that of a non-interest-bearing loan, to be repaid out of earned income over and above operating expenses, payments to hospitals and legal reserve. The benefits of non-profit hospital care should be guaranteed through contracts with member hospitals, which assume the ultimate responsibility for providing service in accordance with contracts with subscribers. Benefits to subscribers should be guaranteed through service contracts with member hospitals, as opposed to cash indemnification contracts for hospital expenses. Of course it is necessary that arrangements be made for provision of service in non-member hospitals in case of serious illness or accident. Payments to hospitals should be based on the cost of services provided to subscriber-patients. It is readily understandable why employees of non-profit plans for hospital care should be reimbursed on a salary rather than commission basis. Promotion and administrative policies should be dignified in nature and consistent with the professional ideals of the hospitals concerned. The service provided should be on a par with the practices of the leading hospitals and the wishes of the attending medical staffs as concerns their respective communities. There should be no interference with the existing relations between physicians and patients. No hospital service plan operated for profit or on a commercial basis will be approved by the American Hospital Association.

If commercial companies can operate a hospital service plan which is better than voluntary hospital service plans, there is no reason for the existence of the latter and the public will be the gainer. A number of commercial companies—some fifty in all—have been or are attempting to match the benefits offered by voluntary hospital service plans. In the last six months a great many insurance companies have offered such contracts in the hope of riding the wave of popularity which has come to hospital service plans. Some of these firms frankly admit that the only purpose of their writing such a contract is to give their agents an opportunity to get their feet in the door and

perhaps make a sale of a more expensive and more profitable contract.

Let us now consider the nature and extent of such services as may be properly included under the hospital service plan. In doing so, let us remember that the benefits for subscribers are represented in hospital service and not in cash. In following the pattern and practices of hospitals in rendering service and exacting charges therefor, there is ample ground for the belief that a plan should include as benefits all the services which hospitals regularly provide and which are involved in their operating costs, and for which charges are established and collected.

Enrollment regulations vary with local conditions. Applications must be submitted in representative groups and no single applications are acceptable. Only employed persons who themselves enroll may submit applications for the dependent members of their families in their immediate households.

Let us now consider what happens when the number of hospital patients under a hospital service plan increases rapidly. The merit of the plan becomes better recognized throughout the community and the momentum of public interest and response increases. The limitations today are represented in the fact that benefits are confined to persons who can make the arrangements for the services of a personal physician. For persons in the group with very low income, financial inability to engage a physician nullifies in effect the benefits of this plan. Government will be urged to act for the low-income group. Social security is generally accepted as necessary, or at least we have become used to it.

We cannot overlook the fact that the medical profession has given freely of its time and services to take care of the medically indigent. If a plan is ever evolved to insure the low-income group for medical services, an extensive campaign of public education will be necessary. Much of the difficulty comes in getting those in the low-income group to seek medical care in time, to say nothing of getting them to go to a hospital when they should.

Since the National Health Conference was held in Washington in the summer of 1938, the American Medical Association through its House of Delegates has made a report which seems to justify the stand taken by the famous group of four hundred and thirty physicians. It now favors government assistance for private institutions. Utilization of hospitals has steadily increased and government funds may be needed for the expansion of hospital facilities and for maintenance if hospitals assume more responsibility for the care of

the indigent and medically indigent. The American Medical Association is strongly opposed to compulsory health insurance, but is unmistakably in favor of what is called socialization of medicine so long as the details of administration are handled locally. If any program to include medical care is to be evolved, it must be initiated carefully in order that all possible safeguards may be set up for eliminating political influence.

A recent editorial in the *New York Times* inquires

What of the many who cannot pay even reduced physicians' fees but can set aside regularly something for medical treatment? They must turn to the public hospitals or private charity. Yet the Association advocates more efficient use of existing hospital facilities in one breath, and in another illogically insists that hospitals should not provide medical care. Moreover, workmen's compensation is to be expected to include sickness benefits. Employers and employees must have nothing to do with salaried or contract medicine.

There is no question but that the public is waiting for a plan which will enlist voluntary agencies in coping with the problem of illness before taxation is invoked. It is important to the medical profession that more concessions be made in order that the country may be convinced that the need of taxation has been reduced to an irreducible minimum.

There is no single community in Vermont large enough to operate a plan of its own unless the work is done by volunteers, and there would be no great amount of earned income to be used in meeting the costs of administration and acquisition. It would be virtually impossible to operate a state wide plan on such a basis. The laws of Vermont are entirely inadequate for the operation of a non-profit hospital service plan, and legislation should be requested of the legislature at its next session.\* Such laws as exist in New York, Pennsylvania and Massachusetts might well be used as a pattern.

I believe it is advisable for the Vermont State Medical Society and the Vermont Hospital Association to consider seriously this problem of group hospitalization. Your people want it, as is evidenced by the tremendous number of inquiries received by those in charge of plans in New York and Massachusetts. These people will find a way to get it, through commercial contracts or by enrolling in non-profit plans by mail. We do not encourage this type of enrollment, but we shall make it available to those communities which are not served by an approved non-profit hospital service plan. It appears logical, then, to attack this problem promptly and determine a likely solution.

21 Milk Street.

\*Legislation in Vermont has recently been enacted.

## CLINICAL NOTE

## TESTOSTERONE PROPIONATE AS A THERAPEUTIC AGENT IN PATIENTS WITH ORGANIC DISEASE OF THE PERIPHERAL VESSELS\*

## Preliminary Report

EDWARD A EDWARDS, M.D.,†  
JAMES B HAMILTON, Ph.D.,‡ AND  
S QUIMBY DUNTLEY, M.S.§

BOSTON, NEW HAVEN, CONNECTICUT, AND  
CAMBRIDGE, MASSACHUSETTS

IN as serious a condition as vascular insufficiency of the extremities, any procedure which gives promise of being effective in treatment deserves early trial of its usefulness. In spite, therefore, of the small number of cases of arterial disease that we have treated with testosterone propionate we feel justified in making this preliminary report.

Our attention was directed to the general vascular effect of testosterone propionate while studying the skin changes in human male castrates. With the recording spectrophotometer,<sup>1</sup> we had noticed that the skin of these subjects showed a lack of arterial blood, although the more venous regions of the body contained an abnormally large amount of venous blood. After treatment with testosterone propionate there was an increase in arterialization and blood volume in those regions normally arterial, such as the head, palms of the hands and soles of the feet. Less constantly there was a diminution in volume of blood in the normally venous areas, such as the lower abdomen and the dorsum of the foot, attended by a shift in the contained blood to a more arterial type. These changes, as well as that in the other skin pigments, are receiving further study.

We have now treated 7 male patients having organic vascular disease with crystalline testosterone propionate. Three of the men presented typical signs of thromboangitis obliterans (Buerger's dis-

ease), the other 4 were arteriosclerotic. In all 7 patients the involvement was major, with loss of the popliteal, femoral and, in one case, the iliac pulsations. The absence of pulsation was checked by the Pachon oscillogram. The signs and symptoms were marked, including small ulcerations in 2 of the patients with Buerger's disease. The testosterone propionate, dissolved in peanut oil, has been given intramuscularly two or three times a week. Adjunctive treatment consisted only of general hygiene, except in the ulcer-free patient with Buerger's disease, to whom eight hours of suction-pressure treatment was given. None of the patients have been followed for more than several months, since treatment of the earliest case was started on July 23, 1938.

Each of these patients with vascular disease showed a lack of skin arterialization by spectrophotometry which involved not only the diseased limbs but also the entire body. The administration of testosterone propionate produced a marked change. As in the case of the castrates, the spectrophotometric curves after treatment showed an early and decided arterialization of the cutaneous blood. Moreover, the after-treatment curves likewise showed an inconstant diminution in the volume of blood in the more venous areas of the body.

Other objective evidence of favorable change was an increase in the systolic pressure of from 6 to 26 mm of mercury in the hypotensive members of this group, and a lowering of hypertensive blood pressures in 2 cases. The ulceration in 1 patient with Buerger's disease has healed, the second has greatly improved. There was marked improvement in the walking ability of all the patients, with delay or abolition of intermittent claudication. Two patients were no longer subject to night pain, which had troubled them previously. Subjectively, the patients reported an increased activity and a feeling of optimism, results similar to those reported previously with male-hormone treatment.<sup>2</sup>

We believe that this material deserves further trial in both organic and functional arterial disease in order to establish clearly its mode of action and to be sure of its harmlessness. It remains to be seen whether its effect will vary in patients with or without testicular deficiency. Moreover, its usefulness in women is so far undetermined and should be approached with caution.

## REPORT ON MEDICAL PROGRESS

## OTOLARYNGOLOGY

CARLYLE G. FLAKE, M.D.\*

BOSTON

IN THE literature of otolaryngology, and in the general literature as well, there have appeared during the past year many articles on subjects within this field, of interest to both the specialist and the general practitioner. It is the purpose of this brief report, in which no comprehensive review of the literature has been made, to consider a few of these articles and to call attention to others.

## NOSE AND SINUSES

*Intranasal Medication*

In recent years workers<sup>1-3</sup> in the field of nasal physiology have demonstrated the importance of ciliary activity and the different effects of various drugs upon it. The drugs commonly used in the nose may be divided into antiseptics, astringents and vasoconstrictors in vehicles of oil, distilled water or physiologic salt solution. Oils, as vehicles, interfere with the normal streaming of mucus, and since they are not miscible with the mucus blanket covering the cilia, the drugs dissolved in them act less effectively. In addition, lipoid pneumonia, as a result of entrance of oil into the lung, is a distinct danger, as reports in the literature indicate.<sup>4,5</sup> While this is especially true in infants and children, the danger exists for adults as well. Tap water and distilled water have also been demonstrated to be harmful to ciliary activity. Isotonic saline is the least harmful of all the common vehicles used in the nose. Walsh and Cannon,<sup>6</sup> in order to demonstrate the effectiveness of some of the antiseptics used in the nose, mixed pus from the lung of a patient with bronchiectasis with equal parts of solutions of the following drugs: Neosilvol 5 and 10 per cent, argyrol 5 and 10 per cent, thymol 1 per cent, menthol 1 per cent and Isedrin Compound. These were allowed to stand at room temperature, and at intervals up to forty-four hours 0.1 cc. of each mixture was cultured and colony counts made. The only drug with any appreciable bactericidal effect was 1 per cent thymol, and this drug had a marked depressant effect on ciliary activity. Further studies were made on the changes produced in the lungs of normal rabbits following the instillation of oil and aqueous solutions of antiseptics, astringents and vasodilators. Oily solutions produced edema, desquamative alveolitis and focal lipoid pneumonia. When mixed with living bacteria cultured from the nose of a rabbit with the

snuffles, they caused, after two or three weeks, granulomatous lesions containing oil. Watery solutions of antiseptics and astringents entered the lungs and caused edema, focal necrosis, purulent bronchitis and bronchopneumonia. Isotonic saline solutions of the vasoconstrictors, ephedrine and Neosynephrine, caused no significant degree of pulmonary damage after intranasal instillation in normal rabbits.

It would seem from the evidence at hand that solutions of drugs in oil should never be used as intranasal medication in infants and children, and should be used with care in adults. Antiseptic solutions are of doubtful value in decreasing the pathogenic flora of the nose, and if the data obtained from animal experiments apply to human subjects as well, there is danger of producing severe lung lesions. Ephedrine is a chemically stable vasoconstrictor which in physiologic solution of sodium chloride does not produce the unpleasant sensations of stinging and burning. These qualifications render it especially suitable for use in children.

Parkinson<sup>7</sup> advocates the following procedure for relief of nasal obstruction in the common cold. The nose is sprayed with a 1 per cent isotonic solution of ephedrine. After five or ten minutes the patient lies on his side, using the shoulder as a fulcrum, with the head bent toward the low shoulder. The solution is then instilled into both nasal chambers and allowed to remain for three to five minutes, after which the head is rotated face down to permit the nasal contents to escape from the nostrils. This position is especially useful in treating children. An alternative position is that of Proetz, in which the patient lies on his back with the head well extended over the edge of a bed or table so that the medication reaches the region of the ostia of the sinuses and remains in contact long enough to be effective.

*Vaccine Therapy*

The effect of vaccine therapy in the common cold was studied by Houser,<sup>8</sup> who gave a series of inoculations to a group of students over a period of four years. His statistics revealed that prophylactic vaccination against colds is followed by a lessened severity and duration of the disease. He recommends six to ten small graduated doses of the vaccine, rather than three large ones. There

\*Assistant in surgery, Harvard Medical School; associate laryngologist, Children's Hospital, Boston.

was little evidence that colds were prevented by this type of therapy.

A controlled study, made in order to determine the value of three different vaccines which were recommended for the prevention of colds, was carried out by Diehl, Baker and Cowan.<sup>9</sup> One group of students received, unknowingly, sterile physiologic salt solution as a control for the subcutaneously administered vaccine, and another group received lactose-filled capsules as a control for the group receiving the vaccine by mouth. Significant was the marked reduction in the number of colds which the control groups reported as compared with the number for the same group in the previous year. Those receiving the vaccine subcutaneously reported 25 per cent fewer colds per person than did the control group. The authors believe that this reduction, although statistically significant, was not sufficient to justify the time and expense necessary to carry out the intensive method of administration used. The groups receiving orally administered vaccine and Rosenow's streptococcal vaccine had as many colds as their control groups.

In certain individuals the common cold is followed by secondary infection with the streptococcus, the pneumococcus or other organisms, and a sinus infection occurs which prolongs the period of convalescence for two or three weeks or even longer. While it is very doubtful if vaccines protect the patient from the virus infection, they often seem to prevent or ameliorate the period of secondary infection. Since administration is simple and rarely attended by any severe symptoms, their use is justified in patients whose colds are commonly followed by a long period of secondary infection.

#### NASOPHARYNX AND PHARYNX

##### Nasopharyngeal Infection

O'Connor<sup>10</sup> reported 59 patients seen during period of three years, because of fatigue and low grade fever of prolonged duration, for which there were no symptomatic, clinical or laboratory features that would allow a definite diagnosis. Of these, 55 were found to have a nasopharyngeal infection. The nasopharyngeal flora was studied in most cases and the predominating organisms were found to be, in order of frequency, *Streptococcus viridans*, *Neisseria catarrhalis*, Type 4 pneumococcus, *Staphylococcus aureus*, *Hemophilus influenzae*, *Streptococcus hemolyticus* and Type 3 pneumococcus. Treatment consisted in the local application of silver nitrate in solutions of varying strength, depending on the degree of congestion or in some cases of a weak solution of zinc sul-

fate. This was followed by the application of a 2 per cent aqueous solution of gentian violet or methylene blue. In resistant cases a 0.5 per cent solution of colloidal iodine was used and followed by the dye. When neither of these combinations of drugs produced results, an autogenous filtrate was made, combined with a water-soluble base, and applied directly to the affected area. During the course of the treatment the patient used saline irrigations and mildly antiseptic drops. A large percentage of O'Connor's patients were relieved by these methods.

##### Infection in Fascial Spaces of Neck

In acute infections involving the fascial spaces of the neck, early operation is often necessary to save life. It is dangerous, as Pearse<sup>11</sup> points out, to treat all cervical infections conservatively with compresses and observation until fluctuation occurs, but it is equally dangerous to operate prematurely on a localizing infection. In Ludwig's angina there is a rapid spread of infection to the neck. Early signs may be edema of the floor of the mouth and limitation of motion of the jaw. A hard, brawny, tender swelling of the neck develops, but no point of fluctuation can be found. The location of surgical approach is the submaxillary-submental fascial space. The floor of this space is formed by the mylohyoid muscle and is continuous posteriorly with the submaxillary space. Incision is made into the submaxillary space in the neck and continued forward, severing the fibers of the mylohyoid muscle and so opening the floor of the space.

The parapharyngeal space lies medial to the internal pterygoid muscle and is bounded by the fascia covering the constrictor muscles of the pharynx and the great vessels. This space may be invaded by parotid, pharyngeal or tonsillar infections. Distention of the space with pus pushes the tonsil and pharynx medially and the parotid laterally. Trismus is due to irritation of the internal pterygoid muscle. Pressure posteriorly on the jugular vein causes cyanosis and distention of the superficial veins. Thrombosis of the jugular vein should be suspected if chills or sepsis occur. After localization early drainage is indicated, and there are several routes which may be employed. The most direct approach is often through the tonsillar fossa, especially if the infection follows tonsillectomy. The external approach may be through the submaxillary space or in front of, behind or above the parotid. The approach used should be determined by the individual circumstances, the factor of prime importance being adequate drainage.

## EAR

*Otosclerosis*

In otosclerosis, foci of altered bone commonly form around the footplate of the stapes, gradually immobilizing it, and producing an obstructive deafness of more or less severity. The inner or perceptive portion of the ear is often unaffected by the process, and hearing by bone conduction is excellent. It has been found that the hearing is greatly improved when a window is made through the bony wall of the external semicircular canal. The chief problem lies in maintaining the patency of this fenestra. Lempert<sup>12</sup> has devised a new approach to this region and a method of covering the fenestra with a flap from the cutaneous posterior canal wall and the mobilized eardrum. This has been successful in a high percentage of his patients.

*Role of Drugs in Congenital Deafness*

The possible relation of some forms of congenital nerve deafness to the prenatal administration of certain drugs which are known to have an adverse effect on the hearing has long interested the otologist. Mosher,<sup>13</sup> after ruling out the various causes of hemorrhage into the labyrinth in his experimental animals, found that when Mapharsen, quinine or sodium salicylate was fed to or injected into the mother, hemorrhages occurred in the cochlea of the fetus but not in the cochlea of the mother. The most extensive hemorrhages were caused by Mapharsen and were located in the scala vestibuli, vestibule and semicircular canals. Quinine and sodium salicylate caused hemorrhages which were nearly always in the scala tympani. The results suggest that quinine and Mapharsen have selective action in different parts of the inner ear. It was concluded that certain drugs pass from the mother to the fetus.

*Chemotherapy*

In the field of chemotherapy the importance of sulfanilamide in the treatment of infections due to the beta-hemolytic streptococcus and the pneumococcus has become daily more evident, and an enormous new literature has grown out of its discovery and use. Principles of treatment have been discussed by Long and Bliss.<sup>14</sup> Keefer<sup>15</sup> has reported his work on the subject, reviewed the important literature and discussed principles and methods of treatment. Pneumococcal meningitis has received the special attention of Finland and his co-workers,<sup>16</sup> who report 6 recoveries out of 10 patients treated. The use of sulfanilamide in otolaryngology was reviewed by Schenck.<sup>17</sup> Recently, the United States Food and Drug Administration has released a new drug, sulfapyridine, for general use. This compound, related to sulfanila-

mide, is even more specific for the pneumococcus, and gives promise of reducing even further the mortality in the desperate complications frequently caused by this organism when it invades the upper air passages and ears.

Clinically the toxic symptoms with sulfapyridine are less marked in children than in adults and are essentially the same as those accompanying the administration of sulfanilamide, namely cyanosis, nausea, vomiting, headache, dizziness, mental confusion, skin rashes, agranulocytosis and anemia. The same precautions observed when sulfanilamide is given should be carried out with sulfapyridine. For adults, Evans and Gaisford<sup>18</sup> used an initial dose of 2 gm., followed every four hours with 1 gm. until 25 gm. had been given. Whitby<sup>19</sup> used a slightly larger dose of 5 gm. in the first twelve hours, in lots of 2 gm., 2 gm. and 1 gm., followed by 1 gm. every four hours. At the Children's Hospital (Boston) Davies<sup>20</sup> gives infants up to the age of two a dose of 1.5 gr. per pound every twenty-four hours. In very sick patients the initial dose may be doubled. The drug may be given suspended in milk or a semisolid vehicle such as mashed banana or apple sauce.

*Deafness in Children*

In children, the lymphoid structures are particularly likely to respond to infection by a great increase in size. When this occurs in the nasopharynx, interference with the function of the eustachian tube, with its resultant impairment of hearing, and attacks of otitis media frequent sequels. Removal of the adenoids and tonsils often relieves the deafness and prevents the recurring attacks of otitis media, but in some children this desirable result of surgery is not obtained. Crowe and Baylor<sup>21</sup> report their observations, made in some cases over a period of ten years, on 60 children with impaired hearing due to eustachian-tube obstruction. They found that, contrary to the classic teaching in otology, loss or impairment for high tones did not generally mean a lesion in the inner ear or nerve. The earliest symptom of tubal obstruction was impaired hearing for tones between 10,000 and 16,000 double vibrations. Gradual progression of the deafness occurred, one octave after another, toward the lower end of the scale, until the speech range was affected and the deafness was noticed.

These authors claim that this type of hearing impairment is due to tubal obstruction from hypertrophied lymphoid tissue around and in the pharyngeal orifice of the eustachian tube, as demonstrated by the nasopharyngoscope. In treating this condition, they remove as much of the lymphoid tissue surgically as can be accomplished without damage to the nasopharyngeal structures.

Using a special applicator, radium, in the total dosage of 2 to 2.5 gram minutes, is administered in small doses at intervals of a month to six weeks on each side of the nasopharynx. If there is diffuse granular hyperplasia the radium therapy is supplemented by roentgen therapy, a total dose of 500 r being given in six treatments at intervals of four days. The results of this type of therapy in their reported cases were excellent.

#### TRACHEA AND BRONCHI

##### *Laryngotracheobronchitis*

In the 127 cases of laryngotracheobronchitis reported in the literature there were 37 deaths. Of the patients who underwent tracheotomy, 51 per cent died. Richards<sup>22</sup> believes that tracheotomy is the treatment of choice, and should be performed before the patient is exhausted or an obstructive emergency arises, for then the hope of recovery is slight.

Diphtheria, spasmodic croup or some other milder forms of laryngeal obstruction should be ruled out before tracheotomy is done. If the patient is not relieved by tracheotomy at least one bronchoscopic examination should be made. Masses of debris accumulate in the trachea and bronchi of some patients and produce severe obstructive symptoms.

As Brennemann et al.<sup>23</sup> point out, drugs play a minor role, if any, in the treatment of the disease. The use of belladonna is to be condemned, for it inhibits the secretions and causes the exudate to be even more sticky and tenacious. Such expectorants as ipecac, ammonium chloride and the iodides are of theoretical and questionable value, and because of their objectionable taste they further harass the sick child and may cause him to refuse other fluids. Saturation of the room air by use of the steam kettle and humidifier, while maintaining the temperature around 75° F., is desirable.

##### *Laryngectomy*

Crowe and Broyles<sup>24</sup> discussed their modification of the single stage procedure for total laryngectomy in selected cases. Their variations included subperichondrial resection of the thyroid cartilage to skeletonize the larynx and avoid injury to the muscles, and the formation of a mucous membrane flap from the posterior surface of the larynx to aid in a tension free closure of the pharyngeal defect.

##### *Laryngeal Stenosis*

Schmiegelow<sup>25</sup> has devised a method of treating chronic cicatricial stenosis of the larynx. If the tracheotomy tube has not been placed as far away from the larynx as possible an inferior tracheotomy is first done. Later the larynx is opened and made as normal as possible by the removal of

webs and strictures. An India rubber drain about 5 cm long is introduced into the larynx and fixed in place by a fine silver wire, which is drawn through the neck and thyroid cartilage and cut off flush with the skin on each side. The drain can be removed from above through the mouth with a laryngeal forceps. The period of treatment averaged about six weeks.

##### *Route of Infection to Lung*

The relation of certain types of pulmonary infection to infection in the paranasal sinuses was further studied by Larsell and his co-workers<sup>26</sup>. Using animals, they introduced streptococci into the sinuses and the lymph nodes receiving drainage from them. They found that viable streptococci reached the lung, liver and spleen from both these sources. The anatomical pathway was by way of the paratracheal lymphatic vessels to the great veins and into the right side of the heart and pulmonary capillaries. The organisms that passed through the lung were evidently filtered out in the spleen and liver.

##### *Bronchiectasis and Sinus Infection*

A clinical study of 75 patients with bronchiectasis was made by Goodale<sup>27</sup> in order to determine the role of sinus infection. Chronic sinus infection was present in 46 patients and 29 had normal x-ray films. Of the latter group 18 had a history suggestive of either recurrent acute or mild chronic sinusitis. Twenty-one patients had pneumonia at the onset not preceded by an acute upper respiratory infection, which would seem to indicate that bronchiectasis can occur without a preceding upper respiratory infection. Patients with bronchiectasis showed an increased susceptibility to sinus infections. The sinus infection may develop subsequently and independent of the pulmonary disease. There was no relation between the side of the chest affected and the location of the infected sinus. The incidence of sinus infection was much lower in patients with one lobe involved and such cases were the most favorable for lobectomy. When the chronic sinusitis had become established the chance for further damage to the lung was increased, owing to the greater susceptibility of the patient to repeated upper respiratory infections. When both ethmoids and antrums were infected the best results were obtained by radical procedures on these sinuses.

##### *Plummer-Vinson Syndrome*

This syndrome is characterized by the symptoms and signs of hypochromic anemia, dysphagia, atrophic changes in the lips and oral mucosa, smooth tongue cracking and fissures of the corners of the mouth, early loss of teeth, changes in the nails and splenomegaly. Johnson<sup>28</sup> states

that the syndrome usually appears at from fifteen to twenty years of age, and never after fifty. Malignant changes which appear in the fourth, fifth or sixth decade may have started with a simple hypochromic anemia at the age of puberty. Anemia and atrophic changes in the oral and pharyngeal mucosa should be looked for in all female patients in this age group who complain of dysphagia before they are classified as neurotics or as having a globus hystericus. Jackson<sup>29</sup> reports that of 110 patients with carcinoma of the esophagus, 87 were at some time diagnosed as neurotics. The postcricoid region was the commonest location for carcinoma, and 90 per cent of all carcinomas in this location are in women. The treatment of Plummer-Vinson syndrome is the administration of iron and careful, repeated endoscopic examination of the hypopharynx and esophagus. If webs are present they must be excised. In the absence of webs or bands, deglutition is often improved by simple diagnostic esophagoscopy and the administration of the proper doses of iron.

## MASSACHUSETTS MEDICAL SOCIETY

## PROCEEDINGS OF THE COUNCIL

Special Meeting, April 26, 1939

A SPECIAL meeting of the Council of the Massachusetts Medical Society was called to order by the president, Dr Channing Frothingham, Suffolk, in John Ware Hall, Boston Medical Library, 8 Fenway, Boston, on Wednesday, April 26, at 10 a m. There were 188 councilors in attendance (Appendix No 1).

The minutes of the regular meeting of the Council held on February 1 were presented by the Secretary as published in the *New England Journal of Medicine* for March 9, 1939. The President announced the minutes approved as published.

The Council voted to approve of the nominations by the President to form a special Committee on Industrial Health which was authorized at the meeting on February 1. The committee is as follows:

Dr W Irving Clark, chairman, Worcester

Dr Noel G Monroe, Middlesex South

Dr Louis R Daniels, Middlesex South

The President announced the appointment of Dr George L Steele, Hampden, as the official delegate to represent the Society at the annual meeting of the Connecticut State Medical Society. Dr Steele is to succeed Dr Theodore L Story who is unable to attend. The appointment was confirmed.

The Council next proceeded to consider the matter for which the meeting was called, and the President asked the secretary of the Committee on Public Relations to present the report which had been adopted by the committee at its meeting on Wednesday, April 5, and a copy of which was mailed to all councilors on April 12 (Appendix No 2). The Council voted to accept the report and to discuss its contents item by item.

After presentation of Item I, the Council voted to express its disapproval of the proposals as submitted by *Health Service Incorporated* (Recommendation 1).

Item II concerned a conference held with a representative of the Farm Security Administration of the United States Department of Agriculture. The committee reported that this matter was submitted for the information of the Council and did not ask for action. In the discussion the President expressed the opinion that the Society should take action approving of the recommendations received from the federal government.

Dr Francis P McCarthy, Norfolk, pointed out that the Council had previously gone on record as opposed to the suggestion but, since no motion was before the Council, no action was taken.

Item III concerned the activities of certain old-line insurance companies which are supplying a form of indemnity insurance to policyholders.

In the discussion, the hope was expressed that the insurance companies might take over the whole problem and thus relieve the Massachusetts Medical Society of the responsibility. In response to an inquiry, it was stated that the average cost of such insurance would probably be about \$10.00 per year.

Dr Michael A Tighe, Middlesex North, chairman of the Subcommittee on Social Legislation and Insurance, spoke of the possibility of extending this insurance through the agents of the companies who already collect certain weekly premiums on life insurance. He expressed the opinion that the utilization of this machinery might be a valuable adjunct. He described in some detail the methods involved. In response to queries he pointed out that any type of insurance for a given year sets very definite limitations on what is covered by the premiums. Larger indemnities may be purchased when larger premiums are paid. As to the quality and adequacy of care under the contract, he stated that the companies are not concerned, since the subscriber is allowed to make his own selection of a physician and the company's responsibility is to supply the money to pay for it. The present contracts are made for groups, especially in industry, and the companies do not attempt to offer this insurance to individuals through their industrial agents. There are no available data concerning the number insured in Massachusetts under this plan.

Dr Edward Mellus, Middlesex South, called attention to the experience under savings bank insurance.

Dr M Victor Safford, Norfolk, quoting from a recent conversation with the secretary of representatives of a large number of liability insurance companies, stated that the companies have not, as a rule, found that health insurance policies are profitable. In his opinion, the matter of health and sickness insurance by commercial companies is in a state of flux, and so far, no general scheme has been agreed on.

The Council *voted to approve the principle of indemnity insurance as offered by old-line insurance companies as representing one means of meeting the costs of medical care* (Recommendation II)

After some further discussion of a general nature, the Council proceeded to consider Item IV of the committee's report. It was decided to read the various Sections under this Item, to allow discussion but to take no action upon the individual Sections until the entire matter had been presented.

Dr Allen G Rice, Hampden, maintained that the Council should agree on a principle before discussing details.

Dr John P Monks, Suffolk, reported that when the matter was discussed by the councilors of Suffolk District it was discovered that the various sections constituted details of a plan and that the various subdivisions of Section 9 in reality constituted the more fundamental parts of the proposal.

Dr Tighe was called to the platform to again give the background for the committee's action. He explained that the study and report resulted from the resolution offered by Dr Ernest L Hunt, Worcester, and adopted at the meeting of the Council on February 1. In the opinion of the subcommittee, the Council should decide certain basic principles.

1 Does the Council desire to do something about the problems which have to do with supplying the cost of medical care?

2 By what method does the Council wish to proceed in so doing?

The methods open were, first, compulsory sickness insurance under the direction and control of the government. This method was disapproved by the Council in 1935. Secondly, there remained three types of voluntary methods (1) that supplied by old-line insurance companies, (2) that fostered and encouraged by certain socially minded persons outside the profession and (3) that fostered by the profession itself. The subcommittee had considered the last three possibilities in detail, and the Council at this meeting voted to approve a voluntary method fostered by old-line insurance companies and to disapprove a method fostered by persons outside the profession. But one alternative remained: the Society could foster a plan. It was not an easy problem to handle and the committee could probably find more objections than could individual members of the Council. In his opinion, the plan presented contained fewer objections and these objections would not be insurmountable.

Dr Tighe called attention to the fact that medical societies in various communities had already adopted comparable schemes and were now endeavoring to put them into effect.

Dr J Harper Blaisdell, Middlesex East, introduced a resolution which, after considerable discussion, was altered and finally passed as follows: *Resolved, That it is the sense of this meeting that the principle of non-profit medical care insurance be approved.*

The President pointed out that the laws of the Commonwealth are in a very unsatisfactory state as to just what can be done from the point of view of contract principles and prepayment. In his opinion, the next step would be to attempt to clarify the laws so that the Society could proceed with a program which would be legal. He made reference to the diversity of opinion which exists in the legal profession as to what can be done under the present laws.

Dr Elliott P Joslin, Suffolk, referred to a recent meeting of the Suffolk councilors at which the general principle of prepayment insurance for medical care had been approved. He stated that the group present at the meeting passed the following motion:

That the Council of the Massachusetts Medical Society instruct its Committee on State and National Legislation to introduce a bill into the Legislature to legalize the development of prepayment plans for medical care and insurance plans for medical care.

It was the opinion of this group of councilors that any proposal presented to the Legislature this year must be simple and that, if such legislation does not pass, there will be a delay of two years. It was believed that it was impossible to recommend to the Legislature any specific details but that, if a general principle was recommended, it might appeal to the Legislature. He offered the above motion for adoption by the Council.

In the discussion which followed it was apparent that the councilors would be unwilling to authorize a committee to proceed with any plan that involved specific details, unless such details were referred back to the Council for approval. There were numerous questions on the implications of Dr Joslin's motion. Dr Joslin finally withdrew his motion.

The President suggested that the Council return to the consideration of the specific proposals in the committee's report, although in his opinion there was something to be said in favor of Dr Joslin's motion since the report appeared to be building a superstructure which might lead to failure of accomplishment because of the present law.

A councilor suggested that, if the Massachu-

setts Medical Society approached the Legislature and attempted to set up a scheme of insurance, it might be declared unconstitutional because it might be regarded as class legislation

The President pointed out that any bill submitted would not contain the name of the Massachusetts Medical Society but would be an enabling act similar to the one which permitted the organization of the Associated Hospital Service Corporation of Massachusetts. He pointed out in response to a query from Dr. George L. Schadt, Hampden, that this enabling act was passed without any specific plan. There was still further discussion of Dr. Joslin's proposal.

The Council proceeded to consider Section 1 of Item IV. Dr. Tighe explained in response to an inquiry that the limit of \$1500 annual income was included by the committee without any attempt at being dogmatic in the fixing of a specific sum. This sum was included to cover the low-income group. He did not believe that the committee could concern itself with the source of income.

In the discussion of Section 2, Dr. Charles F. Wilinsky, Suffolk, pointed out that, if the plan should be limited to those patients who were in hospitals, it would result in overtaxing these institutions which are already under a considerable burden as a result of the hospital-insurance scheme. He expressed the hope that the proposal would be extended to cover home and office care.

Dr. Frothingham stated that there was in existence a definite experience table prepared by a group in California which has worked out a prepayment insurance plan to cover the care of patients in homes and offices as well as in hospitals.

Dr. McCarthy emphasized the importance of what Dr. Wilinsky had stated.

Dr. Tighe stated that he had discussed the matter, raised by Dr. Wilinsky, with the director of the Associated Hospital Service Corporation who did not believe that it would injure the hospital plan.

Dr. Walter Bauer, Suffolk, and Dr. Monks called attention to the European experience which seemed to confirm Dr. Wilinsky's opinion.

Dr. William Dameshek, Norfolk, emphasized the fact that it was already difficult to get patients to leave the hospital under the hospital insurance plan. There appeared to be a distinct tendency for a longer stay in the hospital.

Dr. Charles S. Benson, Essex North, expressed an opinion that it would be wise to leave out reference to hospital insurance in Section 2.

Sections 3 and 4 of Item IV were discussed together.

Dr. Edward F. Timmins, Suffolk, expressed his

concern that the Massachusetts Medical Society should undertake the odium of trying to solve a problem that experience had shown to be practically unsolvable in America and elsewhere, and one in which the insurance companies have found with all their experience and machinery that they cannot make a profit. In his opinion there would be much abuse. Individuals who pay annual dues would attempt to get service in some form, and if this were denied, the Society would be regarded as cold and not benevolent. If in attempting to divide this responsibility, clergymen and others were included in the directing body, the profession would lose its control. He expressed the opinion that the name of the Massachusetts Medical Society ought not to appear and further expressed his sorrow for the men who would serve on the committee. He referred to past experience with various societies whose members paid dues for health and accident insurance and subsequently wrecked their organizations by their demands.

Dr. Leroy E. Parkins, Suffolk, raised the question of what would happen, should subscribers desire services of irregular practitioners.

In response to a question Dr. Tighe gave a brief explanation of what had happened in Michigan where a bill is now pending in the Legislature to authorize the organization of an insurance system to provide for total medical care costs through the organization of a corporation with a board of directors, the majority of whom would be members of the Michigan State Medical Society, although the name of the Michigan State Medical Society does not appear in the bill.

Dr. Timmins was concerned with the possibilities regarding irregular practitioners and felt that the entire scheme should be disapproved since the profession is already severely denounced as a "medical trust."

Dr. Frothingham raised the question as to the desirability of suggesting under the plan that the directors be paid.

Dr. Bagnall gave some additional information regarding the medical service in the District of Columbia, which is handled by a director and nine trustees, the majority being chosen by the medical society. He likewise quoted from an article which indicated that in Battle Creek, Michigan, a plan was being put into operation which provides practically complete medical care to husband and wife and two or more children at \$4.00 per month.

Section 5 of Item IV was presented. Dr. Rice referred to the danger of a lay board making up a fee schedule.

Sections 6 and 7 were considered together. In response to a question Dr. Tighe explained that

The Council *voted to approve the principle of indemnity insurance as offered by old-line insurance companies as representing one means of meeting the costs of medical care* (Recommendation II)

After some further discussion of a general nature, the Council proceeded to consider Item IV of the committee's report. It was decided to read the various Sections under this Item, to allow discussion but to take no action upon the individual Sections until the entire matter had been presented.

Dr. Allen G. Rice, Hampden, maintained that the Council should agree on a principle before discussing details.

Dr. John P. Monks, Suffolk, reported that when the matter was discussed by the councilors of Suffolk District it was discovered that the various sections constituted details of a plan and that the various subdivisions of Section 9 in reality constituted the more fundamental parts of the proposal.

Dr. Tighe was called to the platform to again give the background for the committee's action. He explained that the study and report resulted from the resolution offered by Dr. Ernest L. Hunt, Worcester, and adopted at the meeting of the Council on February 1. In the opinion of the subcommittee, the Council should decide certain basic principles:

1. Does the Council desire to do something about the problems which have to do with supplying the cost of medical care?

2. By what method does the Council wish to proceed in so doing?

The methods open were, first, compulsory sickness insurance under the direction and control of the government. This method was disapproved by the Council in 1935. Secondly, there remained three types of voluntary methods: (1) that supplied by old-line insurance companies, (2) that fostered and encouraged by certain socially minded persons outside the profession and (3) that fostered by the profession itself. The subcommittee had considered the last three possibilities in detail, and the Council at this meeting voted to approve a voluntary method fostered by old-line insurance companies and to disapprove a method fostered by persons outside the profession. But one alternative remained: the Society could foster a plan. It was not an easy problem to handle and the committee could probably find more objections than could individual members of the Council. In his opinion, the plan presented contained fewer objections and these objections would not be insurmountable.

Dr. Tighe called attention to the fact that medical societies in various communities had already adopted comparable schemes and were now endeavoring to put them into effect.

Dr. J. Harper Blaisdell, Middlesex East, introduced a resolution which, after considerable discussion, was altered and finally passed as follows: *Resolved, That it is the sense of this meeting that the principle of non-profit medical care insurance be approved.*

The President pointed out that the laws of the Commonwealth are in a very unsatisfactory state as to just what can be done from the point of view of contract principles and prepayment. In his opinion, the next step would be to attempt to clarify the laws so that the Society could proceed with a program which would be legal. He made reference to the diversity of opinion which exists in the legal profession as to what can be done under the present laws.

Dr. Elliott P. Joslin, Suffolk, referred to a recent meeting of the Suffolk councilors at which the general principle of prepayment insurance for medical care had been approved. He stated that the group present at the meeting passed the following motion:

That the Council of the Massachusetts Medical Society instruct its Committee on State and National Legislation to introduce a bill into the Legislature to legalize the development of prepayment plans for medical care and insurance plans for medical care.

It was the opinion of this group of councilors that any proposal presented to the Legislature this year must be simple and that, if such legislation does not pass, there will be a delay of two years. It was believed that it was impossible to recommend to the Legislature any specific details but that, if a general principle was recommended, it might appeal to the Legislature. He offered the above motion for adoption by the Council.

In the discussion which followed it was apparent that the councilors would be unwilling to authorize a committee to proceed with any plan that involved specific details, unless such details were referred back to the Council for approval. There were numerous questions on the implications of Dr. Joslin's motion. Dr. Joslin finally withdrew his motion.

The President suggested that the Council return to the consideration of the specific proposals in the committee's report, although in his opinion there was something to be said in favor of Dr. Joslin's motion since the report appeared to be building a superstructure which might lead to failure of accomplishment because of the present law.

A councilor suggested that, if the Massachu-

setts Medical Society approached the Legislature and attempted to set up a scheme of insurance, it might be declared unconstitutional because it might be regarded as class legislation

The President pointed out that any bill submitted would not contain the name of the Massachusetts Medical Society but would be an enabling act similar to the one which permitted the organization of the Associated Hospital Service Corporation of Massachusetts. He pointed out in response to a query from Dr George L Schadt Hampden, that this enabling act was passed without any specific plan. There was still further discussion of Dr Joslin's proposal.

The Council proceeded to consider Section 1 of Item IV. Dr Tighe explained in response to an inquiry that the limit of \$1500 annual income was included by the committee without any attempt at being dogmatic in the fixing of a specific sum. This sum was included to cover the low-income group. He did not believe that the committee could concern itself with the source of income.

In the discussion of Section 2, Dr Charles F Wilinsky, Suffolk, pointed out that, if the plan should be limited to those patients who were in hospitals, it would result in overtaxing these institutions which are already under a considerable burden as a result of the hospital-insurance scheme. He expressed the hope that the proposal would be extended to cover home and office care.

Dr Frothingham stated that there was in existence a definite experience table prepared by a group in California which has worked out a prepayment insurance plan to cover the care of patients in homes and offices as well as in hospitals.

Dr McCarthy emphasized the importance of what Dr Wilinsky had stated.

Dr Tighe stated that he had discussed the matter, raised by Dr Wilinsky, with the director of the Associated Hospital Service Corporation who did not believe that it would injure the hospital plan.

Dr Walter Bauer, Suffolk, and Dr Monks called attention to the European experience which seemed to confirm Dr Wilinsky's opinion.

Dr William Dameshek, Norfolk, emphasized the fact that it was already difficult to get patients to leave the hospital under the hospital-insurance plan. There appeared to be a distinct tendency for a longer stay in the hospital.

Dr Charles S Benson, Essex North, expressed an opinion that it would be wise to leave out reference to hospital insurance in Section 2.

Sections 3 and 4 of Item IV were discussed together.

Dr Edward F Timmins, Suffolk, expressed his

concern that the Massachusetts Medical Society should undertake the odium of trying to solve a problem that experience had shown to be practically unsolvable in America and elsewhere, and one in which the insurance companies have found with all their experience and machinery that they cannot make a profit. In his opinion there would be much abuse. Individuals who pay annual dues would attempt to get service in some form, and if this were denied, the Society would be regarded as cold and not benevolent. If in attempting to divide this responsibility, clergymen and others were included in the directing body, the profession would lose its control. He expressed the opinion that the name of the Massachusetts Medical Society ought not to appear and further expressed his sorrow for the men who would serve on the committee. He referred to past experience with various societies whose members paid dues for health and accident insurance and subsequently wrecked their organizations by their demands.

Dr Leroy E Parkins, Suffolk, raised the question of what would happen, should subscribers desire services of irregular practitioners.

In response to a question Dr Tighe gave a brief explanation of what had happened in Michigan where a bill is now pending in the Legislature to authorize the organization of an insurance system to provide for total medical care costs through the organization of a corporation with a board of directors, the majority of whom would be members of the Michigan State Medical Society, although the name of the Michigan State Medical Society does not appear in the bill.

Dr Timmins was concerned with the possibilities regarding irregular practitioners and felt that the entire scheme should be disapproved since the profession is already severely denounced as a "medical trust."

Dr Frothingham raised the question as to the desirability of suggesting under the plan that the directors be paid.

Dr Bagnall gave some additional information regarding the medical service in the District of Columbia, which is handled by a director and nine trustees, the majority being chosen by the medical society. He likewise quoted from an article which indicated that in Battle Creek, Michigan, a plan was being put into operation which provides practically complete medical care to husband and wife and two or more children at \$4.00 per month.

Section 5 of Item IV was presented. Dr Rice referred to the danger of a lay board making up a fee schedule.

Sections 6 and 7 were considered together. In response to a question Dr Tighe explained that

the unit system has been adopted in many places throughout the country. Certain procedures under the plan are assigned so many units of value, the attempt being made to have the value of a single unit represent one dollar. When supplying total medical care costs, the value of the unit will vary from month to month or from quarter to quarter. The real value of a unit in any period is governed by the amount collected during that period minus the cost of the administration. The unit may, therefore, vary in value from one dollar to sixty cents or even less. This was one of the reasons for recommending that the proposal be limited to hospital patients in the beginning, until more information is available as to actual costs of operation.

In answering a question by Dr. Alexander A. Levi, Middlesex South, Dr. Tighe stated that, in case there were surpluses, they would be carried over to meet the bills of the next month when the drain on the treasury might be heavier. Dr. Levi said that a statement to this effect should appear in the section.

Dr. Dameshek stated that much of the discussion was immaterial for the reason that the Society is trying to initiate legislation and that it cannot predict what will happen to that legislation in the Legislature. In his opinion, rules and regulations proposed by the Society might not meet with the approval of the Legislature which in turn might initiate a system of its own.

Under the consideration of Section 8 of Item IV a councilor asked what would happen to the patients of a physician who did not belong to the Massachusetts Medical Society and who could not, therefore, be a member of a hospital staff. In Dr. Bauer's opinion, this would again be a question of the patient's choice, not only of hospital but of physician.

Dr. Lincoln Davis, Suffolk, was of the opinion that the free choice of physician constitutes one of the many difficulties in the plan. The Society wishes to assure good medical care. He did not believe that absolutely free choice of physician could be offered with the expectation of providing good medical care.

Dr. Albert A. Hornor, Suffolk, expressed his regret that, because of illness, Dr. Charles C. Lund, Suffolk, was unable to be present since, in his opinion, certain of the proposals in Section 8 were contrary to what the Committee on State and National Legislation is seeking in the way of licensing hospitals. He recalled that Dr. Lund had said that there should be an insertion providing that a physician should be a member of a hospital staff, permanent or courtesy, if he were to be considered under the term "free choice."

Section 9 of Item IV was presented by Dr. Baghall.

Dr. Joslin again suggested that his original motion might be used if a clause was inserted which would bring it in accord with the first four subsections of Section 9. In connection with a query as to the terms "charitable" and "benevolent" he pointed out that these are used with reference to the organization and not with reference to the physician who operates under the organization.

Dr. Joslin again suggested reconsideration of his motion. This was followed by a long discussion in which a number of the councilors participated. The desirability of referring back to the Council any proposed action by the committee was emphasized. There appeared to be objection to the motion in part because Subsection 5 of Section 9 would be eliminated. There was also a question as to the implications of Section 5, several councilors stating that they believed that the Massachusetts Medical Society as such should not be permitted to go into the insurance business. In Dr. Joslin's opinion his motion proposed an enabling act. There was also a discussion as to the sequence to be adopted in proceeding from this point, and objection was raised as to the words "prepayment plans for medical care."

At the suggestion of Dr. Tighe, Recommendations III and IV of the Committee on Public Relations were read at this time, and these were proposed as an amendment to Dr. Joslin's motion. Dr. Joslin then suggested the withdrawal of his motion so as to simplify procedure.

It was pointed out that, under the recommendations previously discussed, the Massachusetts Medical Society as a corporate body would not enter the picture but that a separate corporation would be set up to carry out the proposals. There was a continued attempt to bring together the views of Dr. Joslin and Dr. Tighe which finally resulted in the following action by the Council, when it was voted that the Massachusetts Medical Society take the initiative in the formation of a corporation, non-profit in character, which shall seek to pay the medical-care costs of patients. Following the passage of this vote, Dr. Joslin again asked consideration of his motion in modified form. As finally presented it was as follows:

That the Council of the Massachusetts Medical Society instruct its Committee on State and National Legislation to introduce a bill into the Legislature to legalize the development of insurance plans for medical care.

The discussion was extensive and at times rather heated. One councilor inquired as to the opinion of the Attorney General concerning what could be done under the present law. It was pointed out, however, that such an opinion could not be

obtained by the Society but would have to come indirectly through one of the state departments, such as the Division of Insurance. The question was finally put, and Dr Joslin's motion was lost.

After some further discussion of a general nature Dr Tighe moved

That the Committee on State and National Legislation be instructed to seek legislation covering the matter of non profit prepayment medical care.

The motion was duly seconded. Following remarks by several councilors, Dr Monks suggested that, if the motion were passed, it might put Dr Lund and his committee in an embarrassing position since they would be asked to do something which they might regard as impossible of accomplishment.

The President pointed out that the committee was not bound to any specific action. Dr Tighe explained that, if enabling legislation were passed, there would be a year in which a plan might be developed. There was again an expression of concern as to whether or not the Massachusetts Medical Society as such was about to enter the insurance business.

Since the discussion involved interpretation of certain terms and phrases, Dr Tighe withdrew his motion and substituted a new one. He moved

That the Committee on State and National Legislation, in collaboration with the Committee on Public Relations, be authorized to seek legislation providing for a system of medical-cost insurance as already adopted by the Council.

There was some opinion that no system had been adopted by the Council. Dr Blaisdell, however, pointed out that certain definite principles had been adopted. The Council was in favor of medical-care insurance with the sentiment clearly in favor of a non-profit organization. In his opinion the two committees are to ask for a simple enabling act which is not a statutory change but an act which will permit the establishment of a non-profit medical insurance scheme. The Legislature can adopt or refuse such a proposal. If permission is granted, it becomes the privilege of any seven men, presumably under the action indicated at the meeting,—seven members of the Massachusetts Medical Society,—to form a corporation. The object of this corporation would be to establish a system of non-profit medical care which will have to be passed on by the Commissioner of Insurance. The conditions of membership, based on income, would be established by the directorate, and before such incorporators submit their plans to the Commissioner of Insurance, they would come back to the Council for final authority to proceed.

There appeared to be some question as to the need for an enabling act, but it was pointed out

that counsel of the Commissioner of Insurance had stated specifically that the Associated Hospital Service Corporation, for example, could not carry out this work except with a type of procedure which would be entirely too cumbersome to handle. It would involve, for example, a contract between every doctor and every hospital. It was counsel's advice that the doctors work out their plan just as the hospitals had worked out theirs.

In response to a question by Dr Monks, the President stated that the enabling act would allow any group of people to form a corporation but that all groups must go to the Commissioner of Insurance to obtain their charter and the approval of the conditions under which they would operate.

It was then *voted that the Committee on State and National Legislation, in collaboration with the Committee on Public Relations, be authorized to seek legislation providing for a system of medical-cost insurance as already adopted by the Council.*

Dr Halbert G. Stetson, Franklin, asked for an expression of opinion from the councilors present as to whether medical care under the proposed plan should be limited to patients in hospitals or whether it should include patients in their homes or in offices.

The President asked for a show of hands and it was discovered that the great majority favored the extension of the plan to include home calls and office work.

The Council adjourned for the Cotting Luncheon at 1:10 p. m.

ALEXANDER S. BEGG, *Secretary*

## REPORT OF COMMITTEE ON PUBLIC RELATIONS

The following report was adopted by the Committee on Public Relations at a meeting on Wednesday, April 5

## MEDICAL CARE PLANS

Several weeks ago, after there had been a submission to the Committee on Public Relations, itself, of several plans whereby those of moderate means might more easily finance their medical care, these plans were referred to the Subcommittee on Social Legislation and Insurance of the Committee on Public Relations for study. Further impetus was given to this study as a result of the action of the Council of the Massachusetts Medical Society in approving a resolution offered by Dr. Ernest L. Hunt in this Council, February 1, 1939. This resolution reads as follows:

Whereas, within our population there is a considerable group who cannot be classed as indigent but whose incomes do not exceed a bare existence level and for whom adequate medical care other than through charity is not provided by any existing agency, and

Whereas, so far this society has taken no effective steps toward a solution of this problem, and

Whereas, agencies outside the ranks of organized medicine are pressing for action looking to the provision of medical service for this low income group for which reason the initiative may pass from our control and result in ill-advised plans detrimental to patient and physician alike, be it therefore

Ordered by the Council that the Committee on Public Relations (or a special committee of five appointed by the Chair) study the problems of medical service for this low income group particularly in relation to voluntary insurance, co-operative or contract service plans, determine the principles which this society may properly endorse, and secure or devise acceptable plans for furnishing and administering such medical service. This committee shall submit its report with recommendations to the Council at a subsequent meeting.

As a preliminary to the study of the several plans which the Subcommittee on Social Legislation and Insurance had before it, it became evident that this subcommittee needed a guide, mainly in connection with principles involving contract practice. The subcommittee therefore adopted as its guide, Chapter III, Article VI, Section 2 and Section 3 as set forth in the Code of Ethics of the American Medical Association, which are as follows

#### CONDITIONS OF MEDICAL PRACTICE

Section 2 — It is unprofessional for a physician to dispose of his services under conditions that make it impossible to render adequate service to his patient or which interfere with reasonable competition among the physicians of a community. To do this is detrimental to the public and to the individual physician, and lowers the dignity of the profession

#### CONTRACT PRACTICE

Section 3 — By the term contract practice as applied to medicine is meant the carrying out of an agreement between a physician or a group of physicians, as principals or agents, and a corporation, organization, political subdivision or individual, to furnish partial or full medical services to a group or class of individuals on the basis of a fee schedule, or for a salary or a fixed rate per capita

Contract practice per se is not unethical. However, certain features or conditions if present make a contract unethical among which are

- 1 When there is solicitation of patients, directly or indirectly
- 2 When there is underbidding to secure the contract
- 3 When the compensation is inadequate to assure good medical service.
- 4 When there is interference with reasonable competition in a community
- 5 When free choice of a physician is prevented
- 6 When the conditions of employment make it impossible to render adequate service to the patients
- 7 When the contract because of any of its provisions or practical results is contrary to sound public policy

The phrase free choice of physician, as applied to contract practice, is defined to mean that degree of freedom in choosing a physician which can be exercised under usual conditions of employment between patient and physician when no third party has a valid interest or intervenes

The interjection of a third party who has a valid interest or who intervenes does not per se cause a contract to be unethical. A valid interest is one where, by law or necessity, a third party is legally responsible either for cost of care or for indemnity. Intervention is the voluntary assumption of partial or full financial responsibility for medical care. Intervention shall not proscribe endeavor by component or constituent medical societies to maintain high quality of service rendered by members serving under approved sickness service agreements between such societies and governmental boards or bureaus and approved by the respective societies.

Each contract should be considered on its own merits and in the light of surrounding conditions. Judgment

should not be obscured by immediate, temporary or local results. The decision as to its ethical or unethical nature must be based on the ultimate effect for good or ill on the people as a whole.

With these principles herein set forth as a guide, the subcommittee proceeded to study the various plans submitted to it, as well as many other plans under consideration throughout the country which were found available.

It was recognized that many of these plans came from groups of well intentioned citizens and that even though the process might be laborious the subcommittee should extend to these groups the courtesy of discussing their plans with them

#### ITEM I

On March 1, 1939, this subcommittee met the representatives of Health Service Incorporated, an organization which seeks to supply medical care to people whose maximum income is \$3000 a year. This organization seeks to be set up under Chapter 180 of the Massachusetts laws, which chapter prescribes the methods by which a charitable institution may be organized

The Committee on Public Relations, in the preliminary discussion of this plan, found certain very definite objections to it, and these objections were set forth in a communication which was sent to Health Service Incorporated. These objections were as follows

1 That as the proposals came to us, free choice of physician upon the part of the subscriber could in no wise be maintained. It was argued in respect to this objection that under this system, into which the subscriber entered voluntarily the mere fact that he had so subscribed gave him freedom of choice of physician. The subcommittee felt that there were two principles involved at this point, and that these principles involved should not be considered as one, or confused. It was pointed out that, of course, the subscriber was free to join or not as he saw fit, but it was also pointed out that once he had joined he was not free to choose any physician, but that he was very definitely limited to those physicians who might be under contract with Health Service Incorporated.

2. That the tentative proposals as they appear to us seemed to indicate that it was the desire of Health Service Incorporated to set up a certain definite place from which many of the services would emanate. In our discussion with this committee, that this was the actual policy of Health Service Incorporated became very clear. Much was said about how well the services of a certain Boston institution were being used in the morning and evening, and how poorly these services were being used in the afternoon.

3 The question as to whether agreement on a schedule of fees should only be arrived at after consultation with local medical societies, did not seem to greatly impress the Health Service Incorporated representatives as important. Furthermore, in our investigation of this plan we found that that part of the plan which proposed to utilize the Associated Hospital Service Corporation as the means of hospitalizing Health Service Incorporated's subscribers was entirely without warrant—no such agreement having been made between the Associated Hospital Service Corporation and Health Service Incorporated.

*RECOMMENDATION I. The Committee on Public Relations recommends disapproval of the proposals as set forth by Health Service Incorporated*

## ITEM II

On March 1, 1939, the Subcommittee on Social Legislation and Insurance met with Mr. Kenneth E. Pohlmann, classified as a co-operative specialist, and employed by the Farm Security Administration of the United States Department of Agriculture. This conference was in connection with the Farm Administration's plans for financing the cost of sickness for approximately 500 Massachusetts farmers and their families, to whom the Farm Administration had made loans averaging between \$400 and \$500. It developed as a result of our conversation that these loans were made only after the individual farmer's capacity to repay the loan was fairly well established. The Farm Administration, in addition to making the loan, sent certain experts to the farm itself to determine the reasons why it was not supporting those who lived upon it. The Farm Security Administration proposes to set aside the sum of \$15 a year, for each of these 500 farmers. It asks the Massachusetts Medical Society to act as trustee of this fund, and also to set up a schedule of fees. This \$15 per family will represent a pool which will be divided into twelve parts, one for each month. This will make available \$625 a month for payment of the doctors' bills of these 500 farmers. In the event that for any given month there is a surplus, when all the doctors' bills for that month have been paid, that surplus shall be carried over and accredited to those months in which, for seasonable reasons, the drain on the fund would ordinarily be greater. In the event that the bills for any given month are greater than the amount contained in the pool, inclusive of that carried over from surpluses of previous months, there will be a pro rata reduction in the amount paid to doctors on their bills. This concerns medical service ordinarily dispensed by a general practitioner, and is exclusive of surgical operations, and so forth. The trustee shall receive \$50 per family per year for services rendered.

*The Committee on Public Relations looks with favor on this plan which has the endorsement of the American Medical Association. We do not now offer it for discussion, but merely for the information of the Council.*

## ITEM III

We think we have it correctly when we say that old line insurance companies are, at present, unwilling to go beyond the supplying of credits in the form of dollars, which may be used toward the costs of medical care. This attitude upon the part of old line insurance companies has profoundly impressed the committee, and has greatly influenced its judgment in setting limitations on what it regards as the major recommendations of this report. An analysis of many such types of insurance contracts, originating in various old line insurance companies, showed very little advantage possessed by one over the other. Such contracts, wherever they do appear, cannot and really do not differ at all, because they are all founded on the same tables and proceed from the same actuarial source.

**RECOMMENDATION II** *The Committee on Public Relations recommends approval of the principle of indemnity insurance as offered by old line insurance companies as representing one means of meeting the costs of medical care.*

## ITEM IV

The committee was greatly impressed by the releases which came from the Michigan State Medical Society

describing the forthright manner in which this organization proposed to meet the costs of medical care for those in the moderate and low income groups. Correspondence with Dr. Foster, secretary of the Michigan State Medical Society, further elaborated and clarified these releases. We shall not enter at this time into the details of this plan.

At this point the committee turned to a consideration of the tentative proposals as offered by Mr. R. F. Cahalane, director of Associated Hospital Service Corporation. As was pointed out by Mr. Cahalane these proposals were his, and did not emanate from the Associated Hospital Service Corporation.

Evolving from these proposals the Committee on Public Relations offers the following principles upon which may be set up an insurance plan, by means of which the costs of medical care may be met for those in the low income group.

**Section 1** Medical care plans should be on a voluntary basis, and available to those of low incomes, as a means of financing the total costs of their medical care. By low incomes is meant family incomes in the aggregate up to \$1500.

**Section 2** Such medical care in the beginning should be limited to that supplied to patients while in licensed hospitals. This assumes the enactment of pending legislation to vest control of hospital licensing in the Department of Public Health. The committee finds that there is some actuarial guidance for such a plan when so limited. There is no such guidance at the present time for extending medical care on an insurance basis to the home and to doctors' offices. The committee believes that out of the experience gained with this limited plan sufficient tables may be set up to enable the plan to be extended at a later date to include home and office care.

**Section 3** The Massachusetts Medical Society should assume the control and the direction of such a medical care plan. The responsibility for the success of this plan, however, should not be borne by the medical profession exclusively. Labor, industry, and the laity generally, the beneficiaries under such a plan, have a responsibility which must be assumed if such a plan is to succeed.

**Section 4** The actual management of such a plan shall be vested in a board of directors, the majority of whom shall be members of the Massachusetts Medical Society. These directors shall be nominated by the President and approved by the Council. The directors may be paid reasonable compensation for their services. Labor, industry, the law and the church might very well be represented on such a directorate. The combining of the business end of this medical care plan with that of a hospital service corporation might very well result in a decreased overhead for both organizations and in other advantages.

**Section 5** Payment of doctors' fees should be on the basis of a fee schedule set by the board of directors.

**Section 6** It may be said that there are two principal factors in determining fee schedules which must be nicely balanced one against the other. It is obvious that if the fee schedule is inadequate, the service will suffer, and if, on the other hand, the fee schedule is too high, the salability of the medical care contract will be reduced. It has become increasingly emphasized

that the insurance principle should be invoked to the end that medical care costs might be spread so evenly over a whole group as to represent no particular burden on any individual member of the group. If this is true then, in the insurance plan which we propose, the matter of fee schedules should not be approached in the spirit that the medical fees must be cut. The thought rather should be to keep the fees as high as is compatible with the salability of the individual insurance contract. The important thing is to bring good medical care to those who individually may not be able to purchase it in the open market. This effort must not be hamstrung at the very outset by an insistence on premiums so low as to make reasonable medical compensation impossible.

Section 7 The committee inclines toward the unit system as the method of choice in the payment of doctors' bills. It does this because this seems the best way to maintain the insurance principle. The value of the unit will vary from month to month, or quarter to quarter, depending on the relation which the amount of doctors' bills presented during that month or quarter will have to the amount of money taken in during that period, after the administrative costs have been set aside.

Section 8 Patients insured under this plan shall have free choice of physician. Such physicians shall not necessarily be members of the Massachusetts Medical Society. Such physicians shall not necessarily be members of regular hospital staffs. The activities of such physicians in the care of hospital patients shall be regulated by hospitals only to the extent to which they have always been regulated.

Section 9 Such a medical care plan as herein outlined can only be set up under Massachusetts insurance laws by a special act of the Legislature. This legislation should provide

- 1 Enabling provisions
2. Adequate public control through the Department of Insurance.

- 3 Non profit basis of operation.
- 4 Declaration of such a plan as charitable and benevolent, and exempt from taxes of state, or political sub-division thereof.
- 5 That business management to be handled as determined under Section 4

RECOMMENDATION III *The Committee on Public Relations moves the adoption in principle of the medical care plan as outlined in the foregoing principles*

RECOMMENDATION IV *The Committee on Public Relations moves that the Council of the Massachusetts Medical Society foster an attempt to obtain the necessary legislation, with the very definite understanding that no system shall be set up under such legislation until it is finally approved by the Council of the Massachusetts Medical Society*

## CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTEMORTEM AND POSTMORTEM RECORDS AS USED  
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT, M.D.

TRACY B. MALLORY, M.D., *Editor*

### RICHARD CLARKE CABOT AND THE CLINICOPATHOLOGIC CONFERENCE\*

RICHARD C. CABOT, the founder of these exercises, died three days ago on May 8. It seems only fitting on this occasion to devote a few minutes of the hour to his memory. I can think of no more appropriate way to do this than to review briefly the history of these exercises which he developed and popularized till they have become one of the most characteristic features of American medical teaching. Let me read to you Dr. Cabot's own version of the story, quoted from a recent letter to Dr. Frederic A. Washburn which will appear in full in Dr. Washburn's forthcoming history of the Massachusetts General Hospital.

In 1895 I began using, in private quiz exercises at my own office, some of the printed case histories which had been used by Dr. Frederick C. Shattuck on the examinations in clinical medicine. Through my association with him I knew the outcome of these cases, sometimes by autopsy, sometimes by surgical operation, and sometimes by lapse of time and clinical observation. Later I began to use these same cases and others like them in exercises given at the Harvard Medical School to the third year class, beginning about 1900. In these exercises there was no association with the pathologist, and no demonstration of postmortem results. The exercises were given wholly by myself, though each student had a copy of the case, as in the clinicopathological exercises later begun. At the end of each case discussion, I simply told the class what the outcome of the case had been. Some of these cases never came to autopsy, and in those the therapeutic result was often part of the evidence as to the diagnosis. Therapeutics could therefore be more interestingly and appealingly discussed than in cases ending with autopsy. Seventy-eight of these cases, with questions about each, were published by me in 1906.

As soon as I began to have the opportunities of ward service at the Massachusetts General Hospital, beginning with 1908, I was much impressed by the undesirable separation between the clinical men and the pathologists. One day I discovered in an old volume of bound records a case diagnosed as neurasthenia (nervous prostration), and looking at the final lines of the record saw that the patient had died and that an autopsy had been performed. Yet the diagnosis of neurasthenia still stood as the only clinical diagnosis,

both on the record and in the index. This curious blunder aroused me so much that I went at once to the Pathological Laboratory and looked up the postmortem record of the case. I found that the patient had died of cancer of the pleura but had had neurasthenic symptoms and vague intercostal pain which had misled the clinicians. What especially impressed me was that the clinical diagnosis had never been changed, presumably because the clinicians were unaware of the postmortem result.

Soon after this, at the beginning of the year 1910, I began, on my own initiative, to hold exercises with the house officers and medical visitors to the hospital—a weekly exercise in connection with Dr. J. Homer Wright, modeled essentially like the later clinicopathological conferences. After the first few years Dr. Oscar Richardson succeeded Dr. Wright. In 1911 I published 100 case histories similar to those which I was using in the exercises just described, but not all with autopsy. Later in the same year I published 300 case histories, most of them with postmortem, under the title *Differential Diagnosis*, Volume I, followed by 317 further cases in 1914, as Volume II. Soon after this my informal and voluntary exercises with the house officers and graduate students became a regular exercise for the third year class in medicine. Later they were scheduled for the fourth year class, and thus continued up to my resignation as professor of clinical medicine in 1933. The exercises were then taken over by Dr. Tracy B. Mallory and given for and with the assistance of the whole medical and surgical staff and for the whole hospital population, interns and students as well as physicians, as they are at the present time, each member of the staff taking his turn at discussing a case.

In 1915 I began having the discussion of these cases taken down stenographically by my secretary, Miss O'Gorman, and sending the printed case records, including the clinical record, the discussion of the case, and the autopsy findings, to a list of physicians who had signified their desire to receive them. This list included not only physicians in the different parts of the United States, but a number in Europe, Asia and Australia. In this work I was assisted by Miss Florence Painter, who prepared the cases for the printer and attended to sending them out to our rather extensive mailing list. Later the same clinicopathological discussions began to be published in the *Boston Medical and Surgical Journal* now the *New England Journal of Medicine* and this has been continued up to the present time [February, 1938].

Dr. Alan Gregg, Director for Medical Sciences of the Rockefeller Foundation, has said "The clinicopathological conference is the wonder and admiration of many of our foreign visitors, who see in it a candor and fearlessness altogether to the credit of American medicine."

For these qualities Richard Cabot by his constant example for thirty five years was unquestionably in large part responsible, and so long as clinics of this type continue here or elsewhere, he can never be forgotten.

TRACY B. MALLORY

\*Read at the clinicopathological conference at the Massachusetts General Hospital on May 11, 1939.

A sixty-three-year-old white married insurance broker was admitted complaining of pains over the left shoulder blade and left upper arm.

About five months before entry the patient noticed a gradual onset of dull aches and pains at the top and bottom of the left shoulder blade, which persisted for about two weeks. At this time, on getting out of his automobile, he experienced a severe sharp pain in the left shoulder blade and upper arm over the deltoid area. It was necessary for him to sit back in the car, and he broke out in cold perspiration. His physician made a diagnosis of bursitis and kept the shoulder strapped for four or five days. The arm was kept in a sling for several weeks and the pain practically disappeared. About two months after onset the patient went swimming, at which time his shoulder again became painful. A few days later after moving some furniture, more severe pains developed. Six weeks before admission he suffered a very acute episode of pain in the shoulder blade and over the entire surface of the left upper arm, treatment and massage were given, and the patient sent home to bed. Following this he was restless, had persisting dull aches and pains was constipated and began losing weight. Four days before entry an episode of severe pain recurred. He described it as a "grating" pain. It occasionally radiated from the shoulder blade through the chest and heart to the breast. There was no dyspnea or palpitation. The pain was accentuated by sneezing, coughing or movement. There was no paresthesia, numbness, or burning sensation in the arm. On the day before admission there was another attack of severe non-radiating pain in the shoulder. He did not have headache. Heat and codeine finally gave relief.

Physical examination showed a well-developed, moderately obese man complaining of pain in the left scapula and down the left arm to the elbow. Many pigmented moles were distributed over the body. Examination of the head and chest was negative, as was that of the shoulders. The blood pressure was 125 systolic, 75 diastolic, in the left arm, and 128 systolic, 80 diastolic, in the right arm. The abdomen was slightly distended with gas. There was moderate left costovertebral tenderness. No masses were palpable. Rectal examination was negative. The prostate was negative. There was moderate limitation of rotation of the cervical spine to both right and left. Neurological examination was negative throughout, in-

cluding the arms. No lymph nodes were palpable. The temperature was 99.5°F, the pulse 75, and the respirations 18.

Examination of the urine was negative. A Bence-Jones protein test was negative. The blood showed a red-cell count of 5,660,000 with 95 per cent hemoglobin, and a white-cell count of 21,900 with 58 per cent polymorphonuclears, 28 per cent small lymphocytes, 12 per cent mononuclears, 1 per cent eosinophils and 1 per cent basophils. A blood Hinton test was negative. The serum calcium was 10.06 mg per 100 cc, the phosphorus 3.24 mg and the phosphatase 3.16 Bodansky units. A lumbar puncture was negative. Two stool examinations were guaiac negative. An electrocardiogram showed a normal tracing.

X-ray films of the cervical spine, chest and left shoulder girdle revealed extensive destruction of the left first rib. The process was entirely osteolytic in nature, without any evidence of new-bone formation. The overlying soft tissues were increased in density, the lung field showing diminished radiance. The head of the left humerus was deformed, due to an old incompletely united fracture. The heart shadow was prominent in the region of the left ventricle. The aorta was tortuous. Examination of the dorsolumbar spine and pelvis revealed no evidence of disease. There were multiple areas of calcification in the prostate. An intravenous pyelogram was negative. On the eleventh hospital day an operation was performed.

#### DIFFERENTIAL DIAGNOSIS

DR. GRANTLEY W. TAYLOR. This history is fairly extensive, but from it I get very little. In the past history there was pain,—which is perfectly adequately accounted for by finding the lesion in the rib,—some constipation, and weight loss, which may be significant. At entry, there were many pigmented moles over the body,—which conceivably might have some significance,—an abnormal white-cell count of 21,900 with not a preponderance of polymorphonuclears, and no other significant findings except the x-ray films which are going to be of much use to us in the discussion of the problem presented by this process. Destructive lesions in the bone are quite like a box of candy. You can shake and rattle and push it around, but until it is opened you cannot tell what is inside. It may be candy, it may be nuts or marbles. With lesions in the bone you cannot say whether you are dealing with a bone tumor, an inflammatory process or some process of a systemic or metabolic nature. You may be deal-

## CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTEMORTEM AND POSTMORTEM RECORDS AS USED  
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT, M.D.

TRACY B. MALLORY, M.D., *Editor*

### RICHARD CLARKE CABOT AND THE CLINICOPATHOLOGIC CONFERENCE\*

RICHARD C. CABOT, the founder of these exercises, died three days ago on May 8. It seems only fitting on this occasion to devote a few minutes of the hour to his memory. I can think of no more appropriate way to do this than to review briefly the history of these exercises which he developed and popularized till they have become one of the most characteristic features of American medical teaching. Let me read to you Dr. Cabot's own version of the story, quoted from a recent letter to Dr. Frederic A. Washburn which will appear in full in Dr. Washburn's forthcoming history of the Massachusetts General Hospital.

In 1895 I began using, in private quiz exercises at my own office, some of the printed case histories which had been used by Dr. Frederick C. Shattuck on the examinations in clinical medicine. Through my association with him I knew the outcome of these cases, sometimes by autopsy, sometimes by surgical operation, and sometimes by lapse of time and clinical observation. Later I began to use these same cases and others like them in exercises given at the Harvard Medical School to the third year class, beginning about 1900. In these exercises there was no association with the pathologist, and no demonstration of postmortem results. The exercises were given wholly by myself, though each student had a copy of the case, as in the clinicopathological exercises later begun. At the end of each case discussion, I simply told the class what the outcome of the case had been. Some of these cases never came to autopsy, and in those the therapeutic result was often part of the evidence as to the diagnosis. Therapeutics could therefore be more interestingly and appealingly discussed than in cases ending with autopsy. Seventy-eight of these cases, with questions about each, were published by me in 1906.

As soon as I began to have the opportunities of ward service at the Massachusetts General Hospital, beginning with 1908, I was much impressed by the undesirable separation between the clinical men and the pathologists. One day I discovered in an old volume of bound records a case diagnosed as neurasthenia (nervous prostration), and looking at the final lines of the record saw that the patient had died and that an autopsy had been performed. Yet the diagnosis of neurasthenia still stood as the only clinical diagnosis,

both on the record and in the index. This curious blunder aroused me so much that I went at once to the Pathological Laboratory and looked up the postmortem record of the case. I found that the patient had died of cancer of the pleura but had had neurasthenic symptoms and vague intercostal pain, which had misled the clinicians. What especially impressed me was that the clinical diagnosis had never been changed, presumably because the clinicians were unaware of the postmortem result.

Soon after this, at the beginning of the year 1910, I began, on my own initiative, to hold exercises with the house officers and medical visitors to the hospital—a weekly exercise in connection with Dr. J. Homer Wright, modeled essentially like the later clinicopathological conferences. After the first few years Dr. Oscar Richardson succeeded Dr. Wright. In 1911 I published 100 case histories similar to those which I was using in the exercises just described, but not all with autopsy. Later in the same year I published 355 case histories, most of them with postmortem, under the title *Differential Diagnosis*, Volume I, followed by 317 further cases in 1914, as Volume II. Soon after this my informal and voluntary exercises with the house officers and graduate students became a regular exercise for the third year class in medicine. Later they were scheduled for the fourth-year class, and thus continued up to my resignation as professor of clinical medicine in 1933. The exercises were then taken over by Dr. Tracy B. Mallory and given for and with the assistance of the whole medical and surgical staff and for the whole hospital population, interns and students as well as physicians, as they are at the present time, each member of the staff taking his turn at discussing a case.

In 1915 I began having the discussion of these cases taken down stenographically by my secretary, Miss O. Gorman, and sending the printed case records, including the clinical record, the discussion of the case, and the autopsy findings, to a list of physicians who had signified their desire to receive them. This list included not only physicians in the different parts of the United States, but a number in Europe, Asia and Australia. In this work I was assisted by Miss Florence Painter, who prepared the cases for the printer and attended to sending them out to our rather extensive mailing list. Later the same clinicopathological discussions began to be published in the *Boston Medical and Surgical Journal* now the *New England Journal of Medicine* and this has been continued up to the present time [February, 1938].

Dr. Alan Gregg, Director for Medical Sciences of the Rockefeller Foundation, has said "The clinicopathological conference is the wonder and admiration of many of our foreign visitors, who see in it a candor and fearlessness altogether to the credit of American medicine."

For these qualities Richard Cabot by his constant example for thirty-five years was unquestionably in large part responsible, and so long as clinics of this type continue here or elsewhere, he can never be forgotten.

TRACY B. MALLORY

\*Read at the clinicopathological conference at the Massachusetts General Hospital on May 11, 1939.

the peripheral blood smear which points to it. We must go back to that white-blood-cell count of 21,900 with a relatively normal differential count. It certainly is not characteristic of infection and not, so far as I know, similar to the blood picture associated with any primary neoplasm of the bone. Plasma-cell myeloma is described as occurring in a single bone, as opposed to the generalized form, but it should be associated with certain characteristic chemical changes in the blood or manifestations in the blood smear. The serum protein is not recorded, but they looked for Bence-Jones protein in the urine and failed to find it, there is no description of plasma cells in the circulating blood.

I confess to being stuck. I think that this patient was explored with the idea of finding what the diagnosis was and that the specimen passed to the pathologist, giving him the privilege of making a diagnosis. I vote first of all for reticulum-cell sarcoma of the bone, and second, for metastatic hypernephroma.

DR. TRACY B. MALLORY: There was one other question that entered the differential diagnosis. Someone suggested Pancoast tumor. I wonder if Dr. Schatzki has an opinion about that.

DR. SCHATZKI: Certainly the picture is not what was originally described by Pancoast. That was a tumor of the superior sulcus which involves the ribs secondarily and also produces a definite Horner's syndrome. The idea of a specific type of tumor or specific disease entity is being gradually abandoned. The Pancoast syndrome still holds, but this case does not fit it.

DR. MALLORY: Dr. Simmons, have you any comment?

DR. CHANNING C. SIMMONS: I saw this case in consultation and know the diagnosis so that I do not think it is fair to say anything. My preoperative diagnosis was, first, plasma-cell myeloma or Ewing's tumor, and second, a metastatic tumor, source undetermined.

DR. HOWARD B. SPRAGUE: It is of some interest that the cardiologist gets into this field once in a while because the patient has pain in the left arm. The story of acute attacks with radiation of pain into the chest, with sweating and collapse, brings up the question of coronary occlusion. In this particular instance I saw the patient before x-ray study and said, "Take an x-ray film of the shoulder because I think he may have a tumor of the superior pulmonary sulcus." I heard later, evidently incorrectly, that the x-ray plate had confirmed this diagnosis. That is all I know about the patient. I assumed anyway that the case was distinctly out of my field.

# PREOPERATIVE DIAGNOSIS

Osteogenic tumor of rib

DR. TAYLOR'S DIAGNOSIS

- 1 Reticulum-cell sarcoma
- 2 Metastatic hypernephroma

# ANATOMICAL DIAGNOSIS

Metastatic carcinoma

# PATHOLOGICAL DISCUSSION

DR. MALLORY: This patient was operated on by Dr. Edward D. Churchill, primarily, I believe, as Dr. Taylor suggested, for the purpose of biopsy and of making a diagnosis, but with the secondary thought that it was conceivable that there was an isolated tumor of the bone that might be cured if it proved to be resectable. An effort was made to resect the first rib, but it was found to be so completely destroyed by tumor that it fragmented with comparatively gentle traction, so it was not possible to take it all out. The central portion was removed and showed on section quite obvious metastatic adenocarcinoma. We were unable to state with any certainty the primary source. In the succeeding weeks that the patient remained in the hospital the search for the primary source was continued and finally something was found in the large bowel which Dr. Schatzki can show us. If I remember correctly, the members of the X-ray Department were not certain that the polypoid lesion was malignant, but in view of the constant metastasis I think that it almost certainly is.

DR. TAYLOR: It is of interest that he had negative guaiac tests. The only thing that might have suggested the diagnosis was slight constipation and loss of weight, which were studied only to the extent of doing guaiac tests on the stools.

DR. SCHATZKI: There is very little visible on the big films of the colon. We have spot films which I suppose were taken over the junction of the descending colon with the sigmoid, where you can see a polypoid tumor measuring about 4 cm in diameter. It has a relatively smooth surface, as do all polypoid tumors of the colon. It is usually possible to say whether a tumor is malignant, but it is never possible to be certain that it is benign. DR. TAYLOR: A single metastasis to bone from the gastrointestinal tract occurs but it is relatively rare. We had an interesting patient who came to the Pondville Hospital with a tumor involving the maxilla on which we were about to operate. In the past history we discovered that she had had a previous operation by Dr. Daniel F. Jones, at the Massachusetts General Hospital, and

ing, furthermore, with destruction due to external pressure. The history may shed some light on what is going on, and you may get positive information from the laboratory data, but more often the history is noncommittal, the laboratory data fall within normal limits and you are shifted back to your hunch which was based on the x-ray film.

DR. RICHARD SCHATZKI. This, for comparison, is the first rib on the right side, which is completely normal. The first rib on the left is only visible in the immediate paravertebral portion and in the region of the calcified cartilage adjoining the sternum. The rest of the rib is destroyed. In place of the rib there is this soft-tissue mass, there is no evidence of new-bone formation in the area of destruction.

DR. TAYLOR. Let us first give a little thought to the possibility of extrinsic pressure. We note with some interest that the surgeons took an electrocardiogram, I dare say because the pain was in the left shoulder and they wondered if it might have a cardiac origin. It is hard to think what kind of cardiac disease could destroy a rib unless it were an aneurysm, and it is difficult to consider aneurysm of the subclavian vessels without some definite abnormality on physical examination in that area, which he lacked. Pressure from a soft-tissue tumor, such as a neurofibroma, would, it seems to me, also necessarily imply the presence of some mass which could be felt, and it might also be reasonably expected to have exerted pressure on some bone other than the first rib, such as the clavicle or a vertebra. I think that we can eliminate extrinsic pressure as a cause of this change. I believe that Dr. Schatzki will agree that this picture is not characteristic of the smooth appearance of the bone defect which is usually associated with extrinsic pressure.

As regards the possible infections, we always must consider, in passing, osteomyelitis, tuberculosis, syphilis and other less common types of infection. The temperature chart was well behaved. There was no evidence of local inflammatory change. The blood Hinton test was negative, and again you see no evidence of bone regenerative changes such as might reasonably be expected in an infectious lesion. Let us also consider lesions such as Paget's disease and osteitis fibrosa cystica which should manifest themselves in some alteration of the chemical constituents of the blood, which is not present in this case. It is a little surprising to me that an operation was performed, apparently with some security, without x-ray films of other parts of the skeleton, I certainly should have been prompted to have had them taken. To be sure we have flat plates and

pyelograms which give access to a great deal more than was immediately investigated. These were negative. It is reasonable to suppose that this lesion is unique and not part of a widely disseminated process.

We are thrown into the group of bone tumors, and I am not aware of any benign tumor which gives rise to a completely destructive lesion in that area. We sometimes see lesions such as hemangiomas which result in a great deal of bone destruction and often excite no real proliferative changes, but I think they would tend to manifest themselves at some earlier age than sixty-three. I think we must place our chief emphasis in diagnosis on malignant lesions of the bone, either primary or metastatic. Against its being metastatic are the facts that the lesion is unique, insofar as we know, that it does not have any other skeletal manifestations and that there is nothing in the history or physical findings to give grounds for suspecting a primary focus. With hypernephroma, we must realize that bizarre metastasis to bone is not unusual and that urological study often fails to reveal the presence of a primary lesion, which may be very small and may become apparent only a long while after the metastatic process has been recognized. When we turn to the primary malignant tumors of bone, first and by all odds the commonest is osteogenic sarcoma, which almost invariably shows evidence of osteoplastic activity, very commonly associated with an elevated phosphatase reaction. It is worthwhile to consider that in osteogenic sarcoma the age in stance tends to be lower, except in association with Paget's disease of the bone, however, there is no evidence of Paget's disease in the skeleton. Ewing's tumor is also one that primarily occurs in a younger age group, its x-ray appearance is by no means characteristic, since it may simulate a considerable number of other bone conditions, but insofar as there is any common or frequent picture of Ewing's tumor, it does not coincide at all with this picture here. Primary Hodgkin's disease of the bone is rare, I know of no way of making a diagnosis except by biopsy or by manifestations of Hodgkin's disease elsewhere. Again, I should like to draw attention to the group of tumors described by Drs. Parker and Jackson\*—the reticulum-cell sarcomas of the bone. Their series of 17 cases persuaded them that it was a disease chiefly of younger age groups, but I think with a small series of that sort you cannot say that it may not perfectly well also manifest itself in older people. There is no entirely characteristic x-ray picture, and no diagnostic feature in

Parker F. Jr. and Jackson H. Jr.: Primary reticulum cell sarcoma of bone. *Surg. Gynec. & Obst.* 68:45-53, 1939.

was present, which would seem to suggest that if there were an obstruction on the right side it had become so chronic that the kidney pelvis had lost its power to contract against the obstruction and hence could no longer cause pain. She had never had any pain over the right kidney or any history of renal colic, which would seem to suggest that if there were an obstruction in the right ureter it had come on gradually, and hence was not the type one would expect to accompany the passage of a ureteral calculus.

The kidney which has lost its function must have done so either because of some destructive process in the kidney, such as an old tuberculosis or a chronic pyelonephritis of years' standing which had destroyed the kidney tissue or because of an obstruction of the ureter which, through back pressure, had prevented the kidney from functioning. Which of these things is the case here, I am not just sure, although the fact that the right kidney outline was unusual in shape but small would seem to suggest a chronic inflammatory process. Of course you might get a congenital atrophic kidney which would cause such a picture, but if there were a hydronephrosis which was responsible for the inability of the kidney to put out the opaque medium we should expect to find a large kidney instead of a small one and probably a tender kidney, although a long-standing hydronephrosis does not continue to be tender in many cases.

The right kidney disease and the bleeding certainly did not come from the bladder, and cystoscopy was of no help in determining the source of the bleeding for at the time of examination the bleeding had stopped. The record does not say whether the catheter was passed by the obstruction, but from the fact that she did not have a good retrograde pyelogram I think we must assume that it did not.

May I see the x-ray films?

DR TRACY B. MALLORY: They have disappeared.

DR SMITH: Non-opaque stones are really quite rare, and as time goes on we find fewer and fewer of them. Furthermore, there are some things about this case which are rather against stone. There was no history of acute renal colic. This is not necessary, but we find it in a very large proportion of cases with impacted renal stone particularly if the stone has been there long enough to cause destruction of the kidney. Another thing which one might think of is a blood clot, however, the duration of the symptoms seems to have been too long. It might possibly be due to a primary tumor in the lower ureter or a tumor which was secondary to papillary carcinoma of the renal

pelvis, which as you know is very prone to metastasize down the ureter. One of the findings which makes me suspect tumor of the ureter is the rather profuse bleeding of the tumor when the catheter was poked against the obstruction. The tarry thick blood from the ureter coming out in a slow oozing stream is also strongly suggestive. If you get bleeding on passing a catheter into the ureter and then the catheter goes a little farther and you drain clear urine, you can be strongly suspicious of a ureteral neoplasm, but we do not have that information here.

I think one might have obtained a little information from vaginal examination. The obstruction was very low, and one probably could have felt the base of the bladder very plainly and could have palpated a mass in the region of the lower ureter.

I believe that the diagnosis lies between stone and tumor of the ureter, either primary or secondary to tumor in the kidney. One gets a good deal of information in these cases from doing the cystoscopy oneself, particularly from the way the catheter goes into the ureter and from how the obstruction feels when one gets against it. With a stone, by persistent attempts, one can usually pass a catheter, and the fact that on all three occasions no catheter was passed makes me think that, with the destroyed kidney, the impassable obstruction, the rather profuse bleeding on instrumentation and the bleeding preceding cystoscopy, the obstruction is more likely to have been due to tumor of the ureter than to a stone.

DR MALLORY: Dr. Kelley, have you any comment?

DR SYLVESTER B. KELLEY: I am the one who missed the diagnosis on this woman. It was difficult for me to forget my first impression of her. She came to see me a number of years ago, complaining of intermittent bleeding, and at that time we passed a catheter 4 cm up the ureter to outline an oval shadow previously described by x-ray study. My thought was that it was a non-opaque stone. Because of economic reasons she declined an operation as long as she was not in great discomfort. However, the bleeding persisted, and she came back about the first of this year for another examination. At that time we cystoscoped her and I thought the appearance of blood clot protruding from the ureter was very unusual. It did not look like a normal blood clot but as if fibrous tissue had invaded it. In view of the negative biopsy, however, I still thought she might have a stone in the lower ureter and proceeded to operate. Through a Gibson incision we exposed the ureter, not without some difficulty because of adhesions. It was larger than the size

looking into the history, we found that it was a primary carcinoma of the colon which had been resected. She had a metastasis to the maxilla, and that was the only metastasis that she had.

DR BENJAMIN CASTLEMAN This patient now has another bone lesion.

DR F DENNETTE ADAMS Is the leukocyte count consistent, inconsistent or common in this type of disease?

DR MALLORY I do not believe it helps one way or the other.

DR SIMMONS I should think it would not be of any value unless there were an ulcerative lesion in the colon.

## CASE 25212

### PRESENTATION OF CASE

*First Admission* A seventy-one-year-old widow was admitted complaining of hematuria.

For about two months the patient had had bouts of hematuria. The amount of bleeding was not recorded. There had been no pain over the kidneys, and no dysuria except for slight discomfort about the urethral meatus during the urinary bleeding. There was slight increase in frequency, but she had nocturia only once a night. There was some discomfort low in the spine. She had not lost weight.

Five years before admission she had had a hysterectomy and an "observation" cystoscopy, which was negative. She had had no symptoms referable to the abdomen or chest and no headaches.

Physical examination showed a very obese woman in no distress. Examination of the head and chest was essentially negative. Examination of the abdomen revealed no masses or spasm. Neither kidney was palpable, and there was no tenderness.

The temperature was 99.8°F, the pulse 95, and the respirations 20.

The urine was slightly hazy but contained no albumin. There were many red cells and a rare white cell per high-power field.

An intravenous pyelogram showed a non-functioning right kidney and a normal left kidney. Parts of what appeared to be the right kidney outline were seen, it was unusual in shape and small. No calculi were visualized in the urinary tract. Cystoscopy and a retrograde pyelogram revealed a non-opaque obstruction in the lower end of the right ureter. Operation was advised but refused, and the patient was discharged on the day of admission.

*Second Admission* (three weeks later) Following discharge the patient had been very well and had had no pain. She had had hematuria on two occasions, with slight associated weakness.

Physical examination was negative, except for slight tenderness in the right upper quadrant. The blood pressure was 150 systolic, 90 diastolic.

The temperature was 98.6°F, the pulse 80, and the respirations 20.

Examination of the urine showed a specific gravity of 1.022, a slight trace of albumin, 100 red cells and 8 white cells per high-power field, and no casts. The blood showed a red-cell count of 4,000,000 with 70 per cent hemoglobin, and a white cell count of 11,700 with 67 per cent polymorphonuclears. The nonprotein nitrogen of the serum was 24 mg per 100 cc, the uric acid 5.9 mg and the protein 7.0 gm.

A retrograde pyelogram showed that the left ureteral catheter extended to the kidney pelvis. The right was obstructed 2 cm from the ureterovesical orifice. No stones were seen in this area. After injection on the right side most of the dye returned to the urinary bladder. A sufficient quantity passed up the ureter, however, to outline an oval filling defect in the ureter just above the tip of the catheter. This filling defect was about 1 cm in width and 1.5 cm in length. Its long axis was in the course of the ureter, and it had the appearance of a non-opaque stone.

On the fifth hospital day a cystoscopic examination showed an essentially normal bladder except that the intravesical portion of the right ureter was unusually enlarged and reddened. Adherent to the right ureteral orifice, which was also unusually prominent, was a large blood clot. It was impossible to pass a catheter more than 0.25 cm up from the right ureteral orifice, and dye could not be injected through it. Two days later the cystoscope was again passed, and with cystoscopic rongeurs the mass of red tissue which protruded from the right ureteral orifice was gradually dissected. It was unusually tenacious for a blood clot and a specimen was taken for biopsy. This showed acute and chronic inflammation, with hemorrhage. As soon as this mass had been removed it was possible to pass a No. 6 catheter about 0.5 cm up the right ureter, where it met obstruction. No fluid could be recovered through the catheter from this area. On the tenth hospital day an operation was performed.

### DIFFERENTIAL DIAGNOSIS

DR GEORGE G SMITH The situation here seems to be that of an elderly woman who came in with very few symptoms except recurring hematuria, a symptom that always must be taken seriously and investigated. She evidently had had very little infection because her temperature had been normal. The urine contained only a few white cells but many red cells. No tenderness

## THE WORCESTER DISTRICT MEDICAL SOCIETY MOBILIZES

For many years all sorts of theories have been advanced and experiments made for the purpose of improving the quality and increasing the scope of medical practice which have not been approved by organized medicine, and lately, the federal government has indicated its intention to attempt a solution of the problems incident to the medical care of certain groups of the people by methods which have not been in harmony with the ideals of the profession.

The consensus of physicians is that the profession can solve its own problems and in conformity with this sentiment, the American Medical Association has suggested the study of conditions existing in counties throughout the nation in order to permit the accumulation of factual data and opinions as to details of procedure which may be applicable

to the needs of such communities, with the understanding that it may be impossible to devise one universal plan which could be made workable in all sections of the country.

A notable response to the recommendation of the American Medical Association has been the action of a committee appointed by the Worcester District Medical Society consisting of twenty-five physicians of Worcester and six nearby towns under the chairmanship of Dr. James C. McCann. Indicative of the quality of this study is the list of co-operating agencies, which include 226 physicians, 43 dentists, 14 nursing groups, 37 pharmacies, 16 hospitals, 15 departments of health, 7 educational institutions, 14 superintendents of schools, 20 boards of welfare, 29 private welfare bodies, the Young Women's Christian Association, the Worcester Girls' Club, the Worcester Employment Agency, the Worcester Swedish Girls' Club, the Society for the Prevention of Cruelty to Children, the Worcester Child Guidance Clinic and the Worcester Associated Charities. The committee made its report to the Worcester District Medical Society at the annual meeting on May 10, and it was published in the May 2 issue of the *Worcester Medical News*, the official publication of the Worcester District Medical Society.

The report concerns a population of 433,000 persons supplied with 1892 hospital beds, 450 physicians, 225 dentists, 109 pharmacies and a large corps of nurses. In this area 6304 patients during the year were referred to hospitals and clinics, and 14,941 were treated free in doctors' offices, homes and hospitals. Dispensaries and clinics gave 18,385 hours of service. In 25 per cent of 2678 deliveries by 87 physicians no fee was charged. It was estimated that 20 per cent of the service given by physicians in this region was free. Only 213 cases reported by all groups, exclusive of the school population, were reported as unable to secure needed service. This shows that those who are sick in the section under investigation are well supplied with medical care and that doctors are contributing a large proportion of time without remuneration, but it does not show why these non-paying patients are unable to pay some proportion of the doctors' fees.

of my thumb, and very much bound down as far up toward the kidney and as far down toward the bladder as I could reach. There was a small abscess in it which I opened. No stones of course were demonstrable. I called Dr. Mallory over to do a frozen section on the wall of the ureter, and he told us that it was probably carcinoma. In view of the condition locally it was unwise to remove the ureter or consider a nephrectomy, so the wound was closed.

The patient made an uneventful convalescence and is now fairly comfortable, up around the house, doing housework and not in any great discomfort. She does pass a little blood now and then, but that does not interfere with her comfort. I do not regret that I did not attempt to remove the ureter. The only further course is to give x-ray therapy if the bleeding becomes bothersome.

#### CLINICAL DIAGNOSIS

Right ureteral calculus

#### DR. SMITH'S DIAGNOSIS

Ureteral neoplasm

#### ANATOMICAL DIAGNOSIS

Epidermoid carcinoma of the ureter

#### PATHOLOGICAL DISCUSSION

DR. MALLORY: A very considerable and diffuse enlargement of the ureter was found, as Dr. Kelley described, and sections show a very extensive, highly malignant carcinoma, apparently of the squamous-cell type. I do not believe that from the data on hand we can say whether it was primary in the ureter or had extended down from the kidney. I have not had enough experience with squamous-cell carcinoma of the renal pelvis to know whether it runs down the ureter like a papillary carcinoma. I have not seen it do so and would not expect it, but this condition is so rare that my experience is very limited.

## ANNUAL MEETING NEWS

The Ladies' Committee for the annual meeting of the Massachusetts Medical Society to be held in Worcester, June 6, 7 and 8, is looking forward with great pleasure toward welcoming the visiting ladies

Several interesting and enjoyable events have been planned. On Tuesday a bus will take us to the Worcester Country Club for lunch. After lunch we shall visit two very lovely gardens. Mrs. Herbert P. Emory has graciously consented to open her country estate. The wild-flower planting, shrubs and trees, together with many perennials, constitute an unusually charming garden with something of an old-fashioned atmosphere. From Mrs. Emory's we shall go to Mrs. Homer Gage's estate. Mrs. Gage is a most cordial hostess and we are indebted to her for welcoming us to her garden, famous for its iris, roses, perennials and a unique Japanese garden with a brook, bridges and a real Japanese teahouse.

Dinner has been arranged at the Worcester Club at six-fifteen Monday evening, following which we shall be welcomed at the Shattuck Lecture to be held in the Hotel Bancroft.

On Wednesday at noon a bus will take us to "The Red Barn" in old Boylston for lunch and then on to Harvard, to visit three very interesting museums "Fruitlands," the old home of the Alcott family and the cradle of the transcendentalist movement, the Shaker exhibit, complete with exhibits of their industries, ways of living and clothes, and finally, the American Indian Museum, which is considered by many the best of its kind in the country. Tea will be served at the Museum Tea Room.

In the evening we shall have the opportunity of

hearing the speakers at the annual dinner at the Hotel Bancroft.

We shall be very grateful if the women who plan to attend these events will send in their names, on the blanks which are attached to the advance programs, at the earliest possible date.

MRS. CHARLES A. SPARROW, *Chairman*

Boston

### BLEEDING IN THE PUERPERIUM

Mrs. E. P. D., a twenty-year-old gravida II, started flowing rather freely on the thirteenth day following a cesarean section.

The familial history was unimportant. The patient's previous illnesses included scarlet fever, measles, whooping cough and chickenpox. She had had rheumatic fever at the age of seven, which lasted for four months, but had had no further trouble after the removal of her tonsils. She underwent an appendectomy at the age of fifteen. Catamenia began at eleven, were regular with a twenty-eight-day cycle, but always lasting nine or ten days, with a great deal of pain on the first day. Her last period was September 20, 1934, making the expected date of confinement June 27. The previous pregnancy in November, 1933, had resulted in a dead baby following version after an unsuccessful attempt at forceps delivery.

The present pregnancy had been uneventful. Physical examination was normal, her highest blood pressure was 118 systolic, 75 diastolic, and she had gained 20 lb. A cesarean was elected on June 22 because of the previous history and because the presenting part was not engaged and the child was estimated to be larger than 8 lb. The baby weighed 8 lb 9 oz.

The convalescence was uneventful until the thirteenth day when she began to flow very freely after she had been up. The blood examination six days after operation showed a red-blood-cell count of 3,920,000 and a hemoglobin of 73 per cent. The day after the first bleeding the red-cell count was 3,100,000, and the hemoglobin 65 per cent. There was a moderate amount of bleeding for several days after the initial hemorrhage, each day small clots, the size of a walnut, were passed and four to five pads were moderately saturated. The

\* A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

As one reads the report the impression is gained that any inadequacies of medical care could be overcome if reported to the proper authorities and requests made for the formation of plans for the payment of doctors' charges from tax funds. One significant opinion expressed in this report is that higher quality of service will be secured for the indigent if the free choice of the physician is assured and if the payment of the doctor at established rates from tax funds is made. The large number of defects found among the school population is explained by the ignorance and apathy of parents, and it is pointed out that the medical profession should have the facts reported to the proper authorities.

In dealing with the problems of the low-income group, some form of voluntary insurance is recommended, and in order to develop efficiency in carrying forward the necessary administrative and correctional procedures, elaborate details of organization are set forth.

Taken as a whole, this report is an illuminating compilation of factual data, with sound conclusions and recommendations of procedure, and reflects credit on the committee which has the honor of presenting the first report to a district society in Massachusetts and through this channel to the Massachusetts Medical Society.

The Worcester District Medical Society accepted the report and voted to authorize its president to appoint a continuing committee for further study and such action as may be indicated.

The next question is, What will come of it? Will it be pigeon-holed as an example of work well done, or will it stimulate a determination to carry forward permanent working organizations designed to solve the questions before the profession and the public? Here is an opportunity to demonstrate the ability of the profession to assume leadership in bringing order out of a complicated situation.

---

#### NATIONAL TUBERCULOSIS ASSOCIATION MEETING IN BOSTON

SINCE its foundation in 1904, the National Tuberculosis Association has met in Boston only once,

in 1918, and we take this opportunity to welcome the Association to Boston for its thirty fifth annual meeting.

The National Tuberculosis Association, organized and maintained by public-spirited laymen and physicians and supported by funds derived from the sale of Christmas Seals, is one of the largest and most important voluntary associations in the United States. Its chief objects are to promote the investigation of tuberculosis, to disseminate information to the medical profession and the lay public concerning the prevention and control of the disease and to arouse concerted community action against it.

There has been a consistent decline in the death rate from tuberculosis in the United States—from a rate of nearly 200 per 100,000 population in 1900 to a probable rate of below 50 for the year 1938. This favorable trend may in part be ascribed to the educational influence of the Association and its numerous affiliates. The promotion of case-finding and the encouragement of adequate hospitalization of the tuberculous throughout the country are important factors.

The program of the annual meeting is published elsewhere in this issue of the *Journal*. The meetings are open to all. Physicians are especially welcome and may avail themselves of this opportunity to become familiar with advances in the study of tuberculosis and allied problems by attending the conference.

The medical clinics at local hospitals on Wednesday afternoon are featured for the first time during a meeting of the Association. As the seating capacity is limited, tickets should be secured in advance.

## MISCELLANY

## THE COMMITTEE OF PHYSICIANS

The following abstract of a statement issued by the Committee of Physicians for the Improvement of Medical Care, Incorporated, has been recently released.

\* \* \*

The members of the committee have embarked on the second phase of its work, the critical analysis of general or national movements toward the reorganization of medical care. It is their intention to subject to scrutiny and to expose to the light of public opinion and more especially to the physicians of this country, projects or actions of government or of organized medical or lay groups.

They have felt constrained to adopt an uncompromising attitude toward projects or measures that obviously violate the fundamental ends for which they have united, namely the protection and improvement of the quality of medical care. But they are equally solicitous that no systems be imposed of such uniform and stereotyped patterns that experiment and evolutionary development will be deterred. In fact, they have proclaimed interest in education and investigation, establishment, maintenance and improvement of standards of competence and merit, the need for expert control, all features that are incompatible with static uniformity.

## THE WAGNER BILL AND ITS IMPLICATIONS

The introduction of the Wagner Bill will undoubtedly accelerate movements that have already begun to initiate projects and to promote legislation dealing with the reorganization of medical services. It is therefore imperative that some attempt be made by the medical profession to develop a constructive point of view in order to protect the best interests of physicians and patients before legislative action is consummated.

In the present statement about the Wagner Bill, attention is confined chiefly to those provisions which, in the opinion of the committee, should be modified or implemented if legislation, under the terms of this bill, is to improve the quality, and, not merely to increase the quantity, of medical care.

*Administrative Authority*

This committee has, in the past, repeatedly asserted that the various departments of the Federal Government, having to do with health, should be consolidated. The advantages of co-ordinated action have been well illustrated by the effective work of the Interdepartmental Committee and its Technical Committee. Similar co-ordination would seem to be essential to the success of a comprehensive health program. It is therefore urgently recommended that all titles except XIV, which deals with disability benefits, be placed under a single authority, to be established.

*Advisory Bodies*

It would be advisable to have under both federal and state authorities, central advisory councils to promote the integration of the program as a whole. It may be nec-

treatment was entirely conservative, oxytocics and rest in bed being prescribed. The red-cell count five days after the original bleeding had increased to 4,600,000, and the hemoglobin to 78 per cent.

**Comment** Routine examinations of the blood before operation are very helpful in determining the amount of blood that is lost during and after operation. The same is true of blood examinations before delivery, early in the puerperium and following any hemorrhage that may subsequently occur.

The drop in this case was not serious, as the red-cell count only went down to 3,100,000 and the hemoglobin to 65 per cent. In spite of hemorrhage which seemed rather alarming, the blood examination showed that the loss was not serious. One should hesitate a little bit more about entering a uterus that bleeds after cesarean section than one does with a uterus that bleeds after normal labor, but conservatism in treating these cases should not be carried too far. Blood examinations furnish intelligent checks. In this case, if the blood picture had shown a marked secondary anemia or if subsequent hemorrhage had occurred, the uterus of necessity would have had to have been invaded, for in no other way can such hemorrhage be controlled.

## DEATHS

**BROWN**—HARRY BROWN, M.D., of Cottage Street, Whitinsville, died May 7. He was in his sixty-ninth year.

Born in Somersworth, New Hampshire, he attended St. Paul's School and Governor Dummer Academy. He received his degree from the University of Vermont College of Medicine in 1895. Dr. Brown also attended the Massachusetts Institute of Technology and had received training in several New York City hospitals, at one time he was connected with the Sing Sing Prison Hospital in Ossining, New York. He was formerly affiliated with the Massachusetts General Hospital, and he had practiced medicine in Boston before going to Whitinsville.

His fellowships included those in the Massachusetts Medical Society and the American Medical Association.

His widow, a daughter and a grandson survive him.

**La FORTUNE**—WILFRED T. La FORTUNE, M.D., of Fairmount Place, Fitchburg, died May 8. He was in his fifty-third year.

Born in Adams, he graduated from the University of Maryland, and received his degree from the Baltimore Medical College in 1910. After serving his internship at the Maryland General Hospital he started practice in Fitchburg in 1911. For twenty-two months he served in the United States Army during the World War.

He was a member of the Massachusetts Medical Society and the American Medical Association.

His widow and two sisters survive him.

**LOWELL**—ALBERT F. LOWELL, M.D., of Gardner, died May 14. He was in his sixty-fifth year.

Born in Burlington, Vermont, he received his degree

from the University of Vermont College of Medicine in 1900, and had practiced in Gardner since 1901.

Dr. Lowell had been senior surgeon of the Henry Heywood Memorial Hospital and consulting surgeon at the State Hospital for the Insane at East Gardner, the Templeton Branch of the Walter E. Fernald School and the Peterboro (New Hampshire) Hospital. For a long time he also served as surgeon for the Boston and Maine Railroad.

His fellowships included the Massachusetts Medical Society, the American Medical Association and the American College of Surgeons. He was a member of the Massachusetts governing board of the Gorgas Memorial Institution, and from 1910 to 1921 was associate medical examiner in the second Worcester district.

**MYRICK**—ALFRED W. MYRICK, M.D., of North Main Street, Randolph, died May 10. He was in his fifty-sixth year.

Born in Kingston, he received his degree from Tufts College Medical School in 1909. Dr. Myrick had practiced in Randolph for twenty-five years and served as a captain in the medical corps during the World War.

He was a fellow of the Massachusetts Medical Society and of the American Medical Association.

His widow and a brother survive him.

*Surgery* Common fractures Daniel J. Sullivan, Manchester

*Pediatrics* Pulmonary infections in childhood MacLean J. Gill, Concord.

pensation of medical care. They cannot, however, expect to arrogate to themselves control of all ancillary services, nor can they deny some voice in the plan to those for whose benefit their services are intended.

Every encouragement should be given to the development of voluntary sickness insurance. Although it cannot be expected to solve all the medical problems of those just above the level of true need, it will assist many to meet their financial obligation.

If hospital insurance is to function widely there must be sufficient well-equipped hospitals, open to all citizens and available to all the doctors of a community for the care of their private patients, subject to standards of competence and merit.

It is highly desirable that hospitals become increasingly the central foci of medical care in their communities. To this end, opportunities should be given for wider participation of the medical profession in the hospitals and clinics.

The separate treatment of each component of health services can only result in multiplication of administrative machinery and discoordination of instrumentalities for the dispensation of care. If, for example, insurance for medical services cannot be entrusted to the agencies that now control insurance for hospitalization, efforts should be made to find more satisfactory governing bodies not to keep two types of insurance which serve a common purpose separated. It is to the interest of both the public and the medical profession that as little as possible of the funds allocated to medical care be diverted for administrative purposes.

A complete plan for voluntary prepayment for medical care must provide all the essential components of medical care. The service offered under this system cannot be allowed to fall below the standards which have been discussed as essential for public medical care of the needy.

Those with family incomes of \$800 to \$1200 (roughly the middle third of our population) can hardly be expected to avail themselves generally of insurance at a cost of 6 to 8 per cent or more of the total family income. The necessities of life at these income levels are too precarious. The economic level at which insurance of this kind especially on a voluntary basis, can become generally operative is probably higher.

There is much evidence that payment on a per capita basis in proportion to the number of patients served or by salary is superior to payment on a fee for service basis. Group medical practice facilitates the operation of these plans. Programs, to be adequate, must at least include devices for the correlation of services, the co-operation of physicians and the economic and efficient utilization of diagnostic and therapeutic facilities.

#### *Compulsory Government Health Insurance*

The opinion has been expressed, with evidence to support it that voluntary prepayment systems will not solve completely the medical problems of the marginal group just above the level of need (below \$1200 per family per annum, for example), because the costs exceed the financial capacity of these people. Unless the institution of a universal or nearly universal tax supported system is contemplated, care cannot be given to the group between the self supporting and the needy without some form of supplementary support. Excessive fees from the well-to-do, by which physicians have been wont to reimburse themselves for their philanthropies, must diminish steadily as voluntary insurance spreads. Moreover if physicians are to be remunerated for their services to the needy it would seem illogical that they should offer gratuitous service to those above the level of need. To neglect the

intermediate group while providing for their more indigent fellows, seems equally inconsistent. It seems clear that the needs of this group can be met completely only by supplementary payments from private or public funds on an insurance basis or by a completely tax supported system.

In spite of these arguments, the committee views with disfavor any attempt to introduce compulsory health insurance widely at this time. If this system of payment for medical care is eventually to be adopted in this country, experimentation is advisable to discover formulas that will avoid the errors of European systems. Whether or not we are favorably inclined to the principle of compulsory health insurance, it is the part of wisdom to establish in advance the general principles which should govern such projects. In most essentials these do not differ from those that have been prescribed for the program for care of the needy.

One great danger to be feared is too niggardly estimation of costs. All available precedents indicate that even the most efficient non-profit groups cannot operate at a cost as low as that set by the government.

In no case can programs be allowed to offer care with quality proportioned to income.

#### *Group Organizations*

Group medical practice, if properly organized at the initiative of physicians or consumers, favors the full utilization of services of specialists and consultants, efficiency and economy in the use of time and facilities and the development of institutions and organizations which will facilitate administration of medical care. It fosters education by mutual contacts between physicians with various training and skills. By centralizing activities and economizing time, it provides to the professional participants leisure for self-improvement and productive efforts. By effecting economies in administration and physical appurtenances, it permits a larger proportion of total income to be used for remuneration of personnel and enlargement of resources and facilities.

#### *Disability Benefits*

It is quite proper that the government refuse to underwrite disability benefits unless it is assured that serious efforts will be made to minimize the incidence and duration of disability.

#### *Education and Investigation*

The bill neglects entirely provisions for the support of general education and investigation. The committee can not too emphatically insist that without such provisions no program that contemplates expansion and improvement of medical care can be considered satisfactory or complete.

essary to establish, under these central councils, expert bodies of a similar nature to deal with special aspects of the program.

These councils should contain representatives of all professional groups concerned. The medical delegation should include representatives from educational and scientific organizations or institutions. It may be necessary or advisable to add lay representatives to present the case of the consumer and the taxpayer. But representation of special interests should be subordinated to the more important point of assembling outstanding persons with imagination, intelligence, expert knowledge and critical judgment.

### *Medical Care for the Medically Needy*

**General Organization** Public health services for all groups of the population should be placed under the control of trained, expert, salaried full time officers selected on the basis of merit.

**Qualifications Under the Means Test** If a program to provide care for the medically needy is to function, it must be predicated upon the total population requiring service, with payment estimated on a per capita basis (This was the principle of the Technical Committee's Proposal 3.) If expenditures are contingent upon illness, there will be a tendency to reduce services to a minimum and to impose obstacles to qualifications. The objective should be to provide care for all those that require it, not merely for those who demand it. Some system will have to be devised for the registration of those entitled to tax supported care. But methods must be found whereby they may be qualified with expedition and without indignity.

**The Components of Medical Care** This committee has already declared that programs should include all the necessary components of medical care (1) adequate public-health services, (2) services of a general practitioner, (3) services of specialists and consultants, (4) access to modern diagnostic and therapeutic facilities, (5) provisions for hospitalization.

There must, of necessity, also be some machinery to integrate and correlate these components.

**Hospitals and Health Centers** The Wagner Bill proposes new expenditures for hospitals and health centers. There can be no doubt that there is need for further institutions of this kind. However, every effort should be made to utilize to the utmost private and public facilities that are already available.

In order that existing institutions may become eligible for government aid, they should be properly equipped to provide the services for which they are intended.

The hospitals must be staffed by qualified physicians and surgeons, and no person should be allowed to assume professional obligations for which he has not demonstrated competence. Standards similar to those of the American boards for certification of physicians as specialists might be established.

If standards of competence are established as qualifications for appointment to the staff of these hospitals and centers, every effort should be made to permit those who can meet these qualifications to participate in the activities of these hospitals and centers and to utilize their facilities. Under the present system, in many communities throughout the country, highly competent young surgeons and specialists are excluded from the local hospitals which, although presumably quasi public, philanthropic institutions, are controlled by small groups of physicians and surgeons, virtually as personal vested interests. This tends

to impair their educational value, to deter physicians from taking full advantage of their facilities, and discourages highly trained men from establishing themselves in practice in these communities.

Special consideration should be given to large general hospitals and teaching institutions, which may require treatment different from that accorded to small community hospitals.

No grants-in aid should be permitted to go to the support of hospitals or other organizations which are conducted as proprietary institutions for private gain. In institutions which are for both needy and self supporting patients, a system of cost accounting which separates expenditures for the two categories must be required.

**Correlation of Services** If the program is to provide all the necessary components of medical care, some means must be provided by which these may be co-ordinated. This purpose is peculiarly well served by group medical practice, properly organized at the initiative of physicians or consumers. Such group activities for the care of the needy could well be centered about hospitals and diagnostic and therapeutic centers. Full correlation with existing public health services must also be provided.

**Estimates of Cost** Experience of non profit organizations already engaged in providing medical services indicates that, under private auspices, full medical care of acceptable quality costs more than \$20—possibly nearer \$30—per capita per annum. In the proposal of the Technical Committee for medical care of the needy, however, expenditure of only \$10 per capita is proposed. No consistent and comprehensive program can depend on the uncontrollable vagaries of philanthropy.

The \$10 per capita is presumably expected to meet costs of administration, hospitalization, personal services including those of physicians, and the cost of all appurtenances required for the proper dispensation of medical care. The public will be in no position to demand efficiency and competence if it will not pay for them. The fixed expenses for physical equipment and administration in such a program are least susceptible of reduction. Without physical equipment, any program will be ineffective because it will provide only exposure of patients to physicians. Physical facilities will be equally useless unless there is some inducement to physicians to utilize them. In some of the government programs already in effect, the most exemplary institutions have been unable to participate because allotments under grants-in aid have been too small to meet the costs of service without some sacrifice of quality.

To embark upon a program that contemplates the expenditure of only \$10 per capita per annum, when this is obviously inadequate, would inevitably sacrifice quality to mere distribution.

### *Voluntary Prepayment for Medical Care*

Obviously no plan can work without the co-operation of physicians and other professional experts, no plan can work well that does not offer opportunities and incentives to these professionals. On the other hand, if the operation of the plan does not benefit the consumers or recipients of medical care, it has not accomplished its purpose. If all parties concerned were to direct their concerted efforts toward the development of programs that would assure the highest quality of care, it should be possible to find formulas for the distribution of authority and for the solution of administrative problems, the two greatest sources of difference of opinion. Physicians cannot be robbed of their natural monopoly of the dis-

Convention, I hereby invite the several bodies entitled under the constitution to representation therein to appoint three delegates and three alternates to the Convention for the Revision of the *Pharmacopoeia of the United States of America* which is to meet in Washington, District of Columbia, on May 14, 1940

Under the Federal Food, Drug, and Cosmetic Act the standards of strength, quality and purity laid down in the *Pharmacopoeia* for the drugs and preparations that it recognizes become the legal standards for such drugs and preparations. As a consequence the manufacturer, the dispensing pharmacist and the physician have a common interest in the *Pharmacopoeia*. The manufacturer is enabled to furnish the pharmacist with officially standardized materials, the pharmacist to dispense, with exactitude, just what the physician desires, and the physician to write his prescriptions in simple terms with confidence in what the pharmacist will dispense. Without the *Pharmacopoeia* there would be chaos. Without confidence in its sponsors the situation would be perilous.

The Convention for the Revision of the *Pharmacopoeia* decides the principles under which the *Pharmacopoeia* is to undergo revision. It also elects the officers of the Convention, Board of Trustees to manage administrative legal and financial matters, and a Committee of Revision, all to serve until the next convention meets.

The Committee of Revision is composed of fifty elected members. Seventeen of these are doctors of medicine representatives of clinical medicine, pharmacology, serology, therapeutics, and so forth. The other thirty-three members belong to pharmacy and the allied sciences, and include representatives of dispensing and manufacturing pharmacy, inorganic and organic chemistry, botany pharmacognosy, biological assay, and so forth.

In the past, the Committee of Revision has included men of the highest rank in the several fields. That it may continue so to do, it is asked that the various bodies authorized to send delegates to the Convention will appoint their full quota of delegates, and will select them from among those of their own people whom they know to be informed and at the same time prepared to attend the Convention.

WALTER A. BASTEDO, M.D., *President*

United States Pharmacopoeial Convention

33 East 68th Street,  
New York City

## REPORT OF MEETING

### SUFFOLK DISTRICT MEDICAL SOCIETY

At a meeting of the Suffolk District Medical Society at the Boston Medical Library, on Wednesday evening January 25, a discussion of recent progress in diabetes was arranged by Dr. E. P. Joslin. Dr. Albert Hornor turned over the chairmanship to Dr. J. P. Monks.

The first paper was presented by Dr. E. P. Joslin "Resume of the Diabetic Situation Here and Elsewhere." He stated that a survey of diabetic deaths by Dr. George W. Lynch has shown that good progress is being made in the treatment of diabetes in Boston. General practitioners are advised to keep in close contact with their patients who have been referred to hospitals, since 165 out of 301 diabetic deaths in 1935 occurred in hospitals. Laboratories are at present well equipped and open day and night for blood analyses. At the Children's Hospital there have been no deaths from diabetic coma since the discovery of insulin. Furthermore, the surgeons are to be

complimented on their record in caring for surgical complications. In the Boston area there are 8000 known diabetic patients and probably as many unknown. In Norway there are half as many. Massachusetts leads the world in the number of such patients. The true incidence of diabetes has not increased, although the gross incidence has, the reason for this is the increased longevity of the population.

Dr. A. P. Joslin presented the second topic "Treatment with Diet and Protamine Zinc Insulin in Hospital and Home." Dr. Joslin emphasized the change in methods of treatment. Whereas the old method was to treat patients for a few months or a year, modern doctors plan treatment to last twenty or forty years. Surveys have shown that 48 per cent of present-day diabetic patients do a full day's work, and another 25 per cent do a three-quarter day's work. In young adults the problem is how to guide the rest of their lives. A good principle to remember is that severe cases rigorously treated often become mild. The essence of treatment is management of the diet. Carbohydrate should be limited to 150 or 200 gm., protein governed by the age of the patient, and fat supplied to provide good balance. Protamine zinc insulin should be begun early, and its administration should be given at an optimum time to be carefully balanced by a proper distribution of carbohydrate ingestion and to be supplemented, if necessary, by regular insulin. The blood sugar curve should fluctuate between 100 and 200 mg. per 100 cc. Patients should be instructed in groups since by this method a kindly companionable spirit of encouragement will prevail and will be of great help to the new patients. It is the careless patient who is difficult to treat. All patients should be constantly reminded that it is cheaper to stay well than to get well. Voided urine specimens are to be carefully watched for glycosuria each day. Dr. Joslin stated that protamine zinc insulin has marked advantages over regular insulin, it is cheaper, allows a life less mindful of the disease and is safer to use.

The third paper was presented by Dr. Henry Baker, in collaboration with Dr. Alexander Marble. Hypoglycemia. Dr. Baker began the discussion. Hypoglycemia is either spontaneous or due to insulin overdosage. Although insulin shock has been used with some success in the treatment of psychoses, one must remember that damage and death are possible sequelae. Usually it is multiple doses that lead to death. A case record was cited for illustration. The patient at autopsy showed marked atrophy of the pancreas which contained many stones, edema of the brain and diffuse capillary hemorrhages. The patient's doctor had given her several doses of insulin under the impression that her symptoms of nervousness were due to the diabetes and not to the early morning hypoglycemia. He should have obtained repeated voided specimens to test for sugar, he actually obtained none. The ferric chloride test is a simple and quick guide of acidosis.

The difference between the shock induced by protamine-zinc insulin and regular insulin is clinically apparent. Whereas the reaction to the latter comes very suddenly in three to four hours and with prodromal symptoms, with the former the reaction comes gradually in twelve to twenty-four hours. The symptoms in regular insulin shock are tremor, sweating and hunger. In the other they are nausea, vomiting, malaise and mental disturbance. As for antidotes, glucose is very effective, but unlike its immediate effect in regular insulin shock, repeated doses may be necessary and the outcome may be doubtful in reactions due to protamine zinc insulin.

Dr. Marble continued the discussion. He stated that the

## ANNUAL PRIZE SUBSCRIPTION

The annual prize subscription offered by the *New England Journal of Medicine* for the best undergraduate contribution to the *Tufts College Medical Journal* has been awarded to Abraham Pollen '40 for his paper 'Present Status of Vitamin B<sub>1</sub> Deficiency,' which appeared in the March, 1939, issue. Honorable mention goes to Stanley L. R. Robbins '40 for his article 'Mode of Action of Therapeutic Agents in Thyroid Disease' in the January, 1939, issue.

## 'YOUR HEALTH' BROADCASTS

The next series of "Your Health" broadcasts, sponsored by the American Medical Association and the National Broadcasting Company and heard over the Blue Network each Wednesday at 2 00 p m, is entitled 'Using Health Knowledge.' It consists of four broadcasts as follows:

### May 31 Checking Up on Health

Periodic health examination and what follows, and why

### June 7 Vacations—Why and How

Making the vacation a real contribution to health and recreation.

### June 14 Never Stop Learning

A new phase of life begins at commencement, and health contributes to success

### June 21 Answering Your Questions

What kind of health questions can be answered and what kind can't without seeing the patient.

## NOTES

The following thirty three appointments to the teaching and research staff of the Harvard Medical School, effective at the beginning of the next academic year, have been recently announced: Halvor N Christensen, Cozad, Nebraska, S.M. Purdue '37, teaching fellow in biological chemistry, William McL. Wallace, now at Robert Packer Hospital, Sayre, Pennsylvania, M.D. Pennsylvania '38, research fellow in biological chemistry, Kenneth E Livingston, Portland, Oregon, A.B. Stanford '36, research fellow in medicine, Frank P. Dawson, now at Middlesex County Sanatorium, Waltham, Massachusetts, M.D. Tufts '31, assistant in medicine, Herbert J. Fox, now at Boston City Hospital, M.D. Duke '35, assistant in medicine, Wallace C. Miller, now at Peter Bent Brigham Hospital, Boston, M.D. Loyola '36, assistant in roentgenology, Lewis T. Stoneburner, 3d, now at Boston City Hospital, M.D. Medical College of Virginia '37, assistant in medicine, Robert Talkov, Dorchester, M.D. Tufts '37, assistant in medicine, Paul B. Beeson, now at Hospital of the Rockefeller Institute for Medical Research, New York City, M.D. C. M. McGill '33, research fellow in medicine, Alexander M. Burgess, Jr., Providence, Rhode Island, now at Boston City Hospital, M.D. Harvard '37, research fellow in medicine, Albert H. Coons, Gloversville, New York, M.D. Harvard '37, research fellow in medicine, Charles P. Emerson, Jr., Indianapolis, now at Boston City Hospital, M.D. Harvard '37, research fellow in medicine, Florence W. Haynes, Boston, Ph.D. Radcliffe '33, research fellow in

medicine, Francis C. Lowell, Cambridge, Massachusetts, M.D. Harvard '36, research fellow in medicine, Charles H. Rammelkamp, now at Barnes Hospital, St. Louis, M.D. Chicago '37, research fellow in medicine, Otto Schales, Brookline, Massachusetts, Ph.D. Frankfurt '35, research fellow in medicine, Francis M. Forster, now at Pennsylvania Hospital, Philadelphia, M.D. Cincinnati '36, assistant in neurology, Ellsworth H. Trowbridge, now at Boston Psychopathic Hospital, M.D. Washington University '36, assistant in neurology, Howard E. Weatherly, now at Boston Psychopathic Hospital, M.D. Iowa State '34, assistant in psychiatry, Samuel P. Hunt, now at St. Elizabeth's Hospital, Washington, District of Columbia, M.D. Columbia '37, research fellow in psychiatry, Leo J. McDermott, Portland, Maine, now at Children's Hospital, Boston, M.D. Harvard '34, assistant in orthopedic surgery, Glidden L. Brooks, Lincoln, Nebraska, now at Children's Hospital, Boston, M.D. Harvard '37, assistant in pediatrics, Charles H. Cutler, now at Children's Hospital, Boston, M.D. Southern California '38, assistant in pediatrics, Harry Shwachman, Roxbury, M.D. Johns Hopkins '36, assistant in pediatrics, Fe del Mundo, Boston, M.D. University of the Philippines '33, research fellow in pediatrics, James B. Blodgett, Detroit, now at Peter Bent Brigham Hospital, Boston, M.D. Harvard '36, assistant in surgery, James B. Campbell, Jamaica Plain, M.D. Harvard '35, assistant in surgery, John H. Crandon, Boston, M.D. Harvard '37, assistant in surgery, Dean W. Tanner, Layton, Utah, now at Peter Bent Brigham Hospital, Boston, M.D. Harvard '35, assistant in surgery, Richard H. Thompson, Boston, M.D. Harvard '34, assistant in surgery, John A. Sandmeyer, Buhl, Indiana, M.D. Harvard '37, Arthur Tracy Cabot Fellow in Surgery, George H. Acheson, Pittsburgh, M.D. Harvard '37, instructor in physiology, Abe Ravin, Denver, M.D. Colorado '32, research fellow in physiology. The following five appointments hold in the Harvard School of Public Health: Francis S. Cheever, Wellesley, M.D. Harvard '36, assistant in bacteriology, Vlado A. Gettung, Pittsburgh, now at State House, Boston, M.D. Harvard '35, research fellow in preventive medicine and epidemiology, Stafford M. Wheeler, Acoaxet, Massachusetts, now at Johns Hopkins Hospital, Baltimore, M.D. Harvard '37, assistant in preventive medicine and epidemiology, James W. Hawkins, Coeur d'Alene, Indiana, M.D. Harvard '35, Charles Follen Folsom Fellow in Preventive Medicine, Ralph H. Heeren, now at University of Iowa College of Medicine, Iowa City, Iowa, M.D. University of Iowa '34, research fellow in preventive medicine and epidemiology. In addition, Spiros P. Sarris, Lowell, now at Massachusetts General Hospital, M.D. Harvard '36, was appointed assistant in surgery at the Harvard Medical School, effective January 1, 1940.

Dr. Emanuel B. Schoenbach, of New York City, has been awarded the Edward Hickling Bradford fellowship for medical research in the laboratories of bacteriology at the Harvard Medical School from January 1 to September 1, 1940. He received his S.B. from Harvard in 1933 and his M.D. in 1937.

## CORRESPONDENCE

### PHARMACOPOEIAL CONVENTION

*To the Editor*—I have recently issued the following call for the Convention for the Revision of the *Pharmacopoeia of the United States of America*:

In compliance with the provisions of the constitution and by laws of the United States Pharmacopoeial

and 3 miscarried. In the 9 cases, progressive toxemia was the rule in all except 1 which showed a spontaneous rise in estrin values. This suggested the method of treatment applied to the third group of 8 patients, in whom the prolactin values had risen. They were given estrin and progesterone intramuscularly, the result being that none miscarried or developed pre-eclampsia. There were seven fetal deaths, 6 in the second group, an incidence of 50 per cent, and 1 in the first group, an incidence of 8 per cent. There was no infant mortality in the group treated with estrin and progesterone. The treatment consisted of 150,000 to 300,000 international units of estrin and 10 to 20 mg. of progesterone, given until the prolactin values began to decline and then reduced in proportion to the decline in prolactin. However, the cost of this was thirty to forty dollars a day per patient! The past histories of the patients in the third group were significant in that 4 had had previous stillbirths, 3 had had normal births and 1 had had a living child born four years before the onset of her diabetes.

Dr E. P. Joslin concluded the program with a discussion of the subject, "The Emphasis Shifts from Treatment to Prevention and Early Detection of Diabetes." Modern treatment is good, and even coma is fairly well managed, but preventive action is poor. Besides putting greater emphasis on earlier diagnoses, one should consider the problem of heredity in diabetes since it is fundamental. Laws against marriage are obviously impossible, however, those with diabetes should be urged to marry non-diabetic individuals. Pincus and White have stated that by computation one out of four of the population is a carrier for diabetes.

Dr Joslin had passed out ballots to the audience, to be filled in with respect to diabetic heredity. He announced that at a gathering of 200 in Philadelphia 30 per cent had had a positive heredity, in Maine, 25 per cent, and in Omaha, 27 per cent. At this meeting the incidence was 35 per cent.

## NOTICES

### CONSULTATION CLINICS FOR CRIPPLED CHILDREN IN MASSACHUSETTS, UNDER THE PROVISIONS OF THE SOCIAL SECURITY ACT

CLINIC	DATE	ORTHOPEDIC CONSULTANT
Lowell	June 2	Albert H. Brewster
Salem	June 5	Harold C. Bean
Haverhill	June 7	Arthur T. Legg
Gardner	June 13	Mark H. Rogers
Worcester	June 16	John W. O'Meara
Pittsfield	June 19	Francis A. Slowich
Springfield	June 21	Garry deN. Hough, Jr
Brockton	June 22	George W. Van Gorder
Fall River	June 26	Eugene A. McCarthy
Hyannis	June 27	Paul L. Norton

### NORFOLK SOUTH DISTRICT MEDICAL SOCIETY

The Norfolk South District Medical Society will conduct its annual outing and dinner on Wednesday, June 14, at the South Shore Country Club in Hingham.

Golf for both gentlemen and ladies will start at one o'clock. Those not wishing to play golf may join the ladies at bridge or contract at two-thirty. Tea will be served at four o'clock. Dinner will be served at seven o'clock and will be accompanied by dancing, entertainment, moving pictures and the awarding of prizes. Dr James M. Ward is the general chairman.

### BOSTON DOCTORS' SYMPHONY ORCHESTRA

*Nicola Slonimsky*

Rehearsals of the newly organized Boston Doctors' Symphony Orchestra, conducted by Nicola Slonimsky, are held every Thursday evening at 7:30 at Hampton Court Hotel, 1223 Beacon Street, Brookline.

Membership is still open. All physicians, dentists and medical and dental students who are interested should communicate with Dr. Julius Loman, Pelham Hall Hotel, Brookline (BEA 2430).

### NATIONAL TUBERCULOSIS ASSOCIATION

The thirty-fifth annual meeting of the National Tuberculosis Association will be held in Boston on June 26, 27, 28 and 29. All the meetings, except the clinics as indicated, will be held at the Hotel Statler. The sessions are open to any physician, and Dr. Chesley Bush, president of the Association, extends a cordial invitation to those readers of the *Journal* who are interested. Attention is called to the limited seating capacity at the various medical clinics, to which admission will be by ticket only. There will be no registration fee.

Those parts of the program that appear to be of interest to the physician and laboratory worker are given below.

\* \* \*

#### OPENING GENERAL MEETING

Monday, June 26, 8:15 p. m.

Address of the President. Chesley Bush, M.D., Livermore, California.

Report of the Managing Director. Kendall Emerson, M.D., New York City.

Award of the Trudeau Medal. Charles J. Hatfield, M.D., Philadelphia, Pennsylvania.

Report of the Committee on Nominations. W. Atmar Smith, M.D., Charleston, South Carolina.

#### JOINT MEDICAL SESSION

##### PATHOLOGICAL AND CLINICAL SECTIONS

Tuesday, June 27, 9:30 a. m.

Symposium. Genito-urinary tuberculosis.

Pathological Aspects of Genito-Urinary Tuberculosis. Oscar Auerbach, M.D., Sea View Hospital, New York City.

Modern Concepts of Urogenital Tuberculosis. Gilbert J. Thomas, M.D., University of Minnesota Medical School, Minneapolis, Minnesota.

Symposium. Spinal tuberculosis.

Pathological Aspects of Spinal Tuberculosis. T. A. Willis, M.D., Cleveland, Ohio.

Early Recognition and Treatment of Tuberculous Involvements of Vertebral Bodies. Mather Cleveland, M.D., New York City.

incidence of serious hypoglycemia is very low. Single injections are virtually unknown to cause death except in the presence of complications. He next related the history of a sixteen year-old girl with chronic hypoglycemia whose chief complaint was a tendency to drowsiness and unconsciousness in the early forenoon. In 1933-1934 she was studied at the Massachusetts General Hospital, and an exploratory laparotomy for adenoma of the pancreas was performed. No tumor was found, and a biopsy showed normal tissue. The patient was well until 1938 when the attacks recurred. After an unusual attack in school, she was admitted to the Boston City Hospital where further studies were carried out. She was referred to the Deaconess Hospital where a fasting blood sugar value of 27 mg per 100 cc. was obtained. An increase in the 3 a m meal prevented the early morning attacks. Two sugar tolerance curves significantly demonstrated definitely low blood sugar values in the fourth to the sixth hour. A tumor was considered most likely and with the realization that along present lines the patient would lead a nervous hampered life, operation was advised and performed. After three hours of careful exploration of the pancreas, a 1-cm. tumor nodule was found in the head of the pancreas. Its position was such that surgical removal was very difficult, but this was accomplished. The patient has had an uneventful postoperative course, and her fasting blood sugar level is now normal. The pathological report stated that the tumor was a benign adenoma of the islets of Langerhans. The tumor was a dull red, encapsulated mass. In cases of chronic hypoglycemia one must consider liver, thyroid, and pituitary disease in the differential diagnosis.

The next paper was presented by Dr. Howard Root, "Diabetic Coma." He said that diabetic coma cannot be entirely eliminated because there are too many variable factors concerned, such as the diet, the insulin and the course of the disease itself. It is primarily due to a disturbance in carbohydrate metabolism, and insulin is a specific in treatment which has no substitute. The onset is always gradual, taking hours or even days, with increasing weakness, a clouding of the mentality and glycosuria. In a later stage the pulse and respiratory rates go up, and there are polyuria and ketonuria. Progressing still farther, respiration becomes feeble and shallow and ketone bodies disappear from the urine, due to failing kidney function. The terminal stage is one of anuria and requires extremely rigorous treatment with a constant intravenous drip of saline. Meager doses of insulin are practically useless, insulin must be given generously.

Death from diabetic coma can be prevented by early diagnosis. In one series of cases 20 per cent of the patients were in coma when first diagnosed. General care following recovery is as important an element of treatment as the emergency measures. Following an attack, resistance to infection is markedly reduced, and 16 per cent of such patients acquire pulmonary tuberculosis within three to five years.

Dr. Richard Wagner spoke on "Peculiarities of Therapy of Diabetic Children on Two Continents." Dr. Wagner had been in charge of a special diabetic clinic for children in Vienna before coming to Boston to work on the same problem. He stated that in Vienna he found that diabetic children were very liable to pyorrhea and periodontal disease, which was often severe enough to cause the loss of all their teeth. This he finds to be a rarity in Boston. Assuming the disease process and the insulin to be the same, he believes that there might be a hereditary predisposition for both diseases. In addition, fruit and foods rich in vitamin C are economically difficult to procure and their ingestion has not become a habit in Vienna, as it has in Boston.

Pulmonary tuberculosis occurring in diabetic children is usually fatal. Whereas in Vienna, Dr. Wagner had found an incidence of 9 cases of the adult form of tuberculosis in 192 diabetic children, in Boston the incidence is 1 in 400. In Vienna, 30 per cent of children between the ages of seven and eight years had positive tuberculin tests, and 50 to 60 per cent of those fourteen years old. In Boston, 3 per cent of fourteen-year-old children are tuberculin positive.

Dr. Howard F. Root read a paper on "A Resurvey of Dr. Harvey Cushing's Patients with Acromegaly and Young's Experimental Pituitary Diabetes." The theory that a pathologic process in the pituitary gland is responsible for diabetes has often been refuted because no lesions could be demonstrated. However, it is well known that a clinical syndrome may exist without demonstrable pathologic changes in an organ. Even in diabetes itself only 70 to 75 per cent of the cases show changes in the pancreas and liver. Houssay has demonstrated that hypophysectomy of a dog whose pancreas had been previously removed caused the induced diabetes to become milder. Young, of London, injected anterior pituitary extract into a normal dog and found that he could thus produce diabetes more like the real disease than that produced by pancreatectomy, and that it varied from the mildest to the most severe degree of diabetes. Best, of Toronto, removed the pancreas in such a dog and found that the diabetes became no worse. Pathologically, the islets of Langerhans showed an even degeneration.

In a review of 153 cases of acromegaly at the Peter Bent Brigham Hospital it was found that 17 per cent of the patients had diabetes and in all of these the diabetes was secondary by one to twenty-two years. Radiation of the pituitary or its surgical removal produced no change in the diabetes. The degree of severity of the disease and its response to insulin varied in no great manner from the usual non-acromegalic type. Acromegaly is rare in diabetic patients, 5 cases in 15,000 being reported in one series. Dwarfism occurs in 5 per cent of the progeny, and other glandular dyscrasias are also common. There is splanchnomegaly in acromegalics with or without diabetes, there is no splanchnomegaly in patients with uncomplicated diabetes.

Dr. Priscilla White discussed "Thirty Three Pregnancies in Diabetic Patients in 1938 and Studies Thereon." In the pre-insulin era only every other pregnancy terminated successfully. Diabetes does not affect maternal mortality so much as it causes miscarriages, stillbirths and neonatal deaths. Severe diabetic coma or severe hypoglycemia is not compatible with the birth of a living child, of course, but even the most carefully regulated diabetic gravida often fails to give birth to a live infant.

In an effort to determine the cause of these stillbirths, studies on hormones have been carried out. In 1930, Murphy reported an excess of prolan excretion in diabetics. Smith and Smith studied hormone-excretion values in patients with pre-eclampsia and with diabetes, having found that 30 per cent of the former have diabetes. Dr. White presented the hypothesis that stillbirths are not primarily due to the diabetes but to the associated toxemia, as evidenced by edema, rise in blood pressure and albuminuria, the onset of which is now predictable two to six weeks in advance by the rise in serum prolan. Thirty-three diabetic patients had weekly prolan values determined. They can be divided into three groups. The first group of 13 cases showed normal prolan values and had perfectly uneventful clinical courses. In the second group of 12 cases the prolan excretion was elevated, but no special treatment was given, 9 developed pre-eclampsia

## MEDICAL CLINICS\*

## JOINT SESSION OF PATHOLOGICAL AND CLINICAL SECTIONS

Wednesday, June 28

## MEDICAL CLINIC NO 1, BOSTON CITY HOSPITAL, 2 00-4 00 P M

Acute and Chronic Mediastinitis Chester S Keefer, M.D., associate professor of medicine, Harvard Medical School, associate physician, Thorndike Memorial Laboratory, Boston City Hospital

Pulmonary Aspects of Cardiovascular Disease Soma Weiss, M.D., associate professor of medicine Harvard Medical School, associate physician, Thorndike Memorial Laboratory, Boston City Hospital, director, Second and Fourth Medical Services Boston City Hospital

X Ray and Clinical Manifestations of Boeck's Sarcoid Theodore L. Badger, M.D. assistant in medicine Harvard Medical School, chief of Thoracic Clinic, Boston City Hospital

Parenchymal Lesions of the Lung in Lymphoma Henry Jackson, Jr., M.D., assistant professor of medicine, Harvard Medical School, associate physician, Thorndike Memorial Laboratory, Boston City Hospital

Pulmonary Disorders in Diseases of the Blood. George R. Minot, M.D., professor of medicine, Harvard Medical School, director, Thorndike Memorial Laboratory, Boston City Hospital

Actinomycosis of the Lung and Pleura. Elliott C Cutler, M.D., Moseley Professor of Surgery, Harvard Medical School, surgeon-in-chief, Peter Bent Brigham Hospital, and Robert E. Gross, M.D., instructor in surgery, Harvard Medical School, resident surgeon, Peter Bent Brigham Hospital.

Tuberculosis in a Children's Hospital A fifteen-year survey Clement A Smith M.D., instructor in pediatrics, Harvard Medical School, associate physician, Children's Hospital

Cardiac Pseudo-Tuberculosis Merrill C Sosman, M.D., assistant professor of roentgenology, Harvard Medical School, roentgenologist, Peter Bent Brigham Hospital

Tuberculosis in the Students of the Harvard Medical School Roy M. Seideman, M.D., Commonwealth Fund, Tuberculosis Division, Massachusetts State Department of Health

In connection with Clinics No 2 and No 4 special bus transportation will be provided at a nominal cost. The clinics are open to all physicians attending the meeting. Admission however will be by ticket only. Please write for reservations to Dr. Frederick T. Lord, 305 Beacon Street, Boston, indicating which clinic you wish to attend and giving your preference for other clinics in case you cannot be admitted to your first choice. Clinics may be designated by number or by the hospital at which they are to be held. Early application for tickets is suggested especially since the seating capacity of all the amphitheatres is limited.

## AUGUSTIN BELLOSTE AND THE TREATMENT FOR AVULSION OF THE SCALP

### The Odd History of an Operation in Head Surgery

LUTHER M. STRAYER, M.D.

STRATFORD, CONNECTICUT

THE perforation of the outer table of the skull in cases of avulsion of the scalp, in which periosteum is removed from the calvarium, is a procedure advised in textbooks of surgery of today, such as Homans<sup>1</sup> and Christopher.<sup>2</sup> In tracing the recorded references to the operation from these textbooks, James Robertson, through his son Dr Felix Robertson,<sup>3</sup> who wrote in the *Philadelphia Medical and Physical Journal* in 1806, has been credited with originating the idea. And originator he was, so far as concerns all periodical literature since 1850, including the reports by all modern surgeons who have used the procedure and recorded their experiences with it.

A book entitled *Remarkable Cases in Surgery* by Paul Eve,<sup>4</sup> and appearing in 1857, however, contains another account of the operation. It is here reprinted in full.

Dr Felix Robertson, the President of the Trustees of the Medical Department of the University of Nashville was born in 1781, and was the first male child born in Nashville. In retiring from the presidency of the Tennessee Medical Society, April, 1855, he delivered an address of which the following is an extract, taken from the *Nashville Journal of Medicine and Surgery* vol. viii, 1855.

On the 11th of January 1781 he who now addresses you was born, and David Hood, in passing from the lower to the upper fort was fired on by Indians in ambush at the Sulphur Spring, in the northern part of the city. He was pierced by three balls, and fell on his back apparently dead. The Indians rushed on him and trampled him, and stamped him on the back of the neck to dislocate it, and left him, believing he was dead. He lay perfectly still for a long time as it seemed to him, and, when he believed they had gone, he cautiously peeped about and could not see them. He then got up, and slowly wended his way toward the upper fort, a most pitiful looking object, as you may imagine but what must have been his horror when, getting near the top of the bank, he saw the whole company on the hill but a few steps from him. He

said he saw their white teeth as they laughed outright at his strange figure. He turned and tottled back as fast as his little strength enabled him, some four or five firing at him as he turned back, two balls wounding him slightly. They did not attempt to pursue him, and after passing down the ravine a little way his strength entirely failed him, he crept into the brushwood, and lay there until men went out from the forts, and found him, and conveyed him in. My father reached home late that night from a trip to Kentucky, and early next morning went in to see Hood expecting to find him, if not dead, a very forlorn case. On inquiring of David how he was, he replied "Not dead yet, and I believe I would get well if I had half a chance." My father told him he should have a whole chance and David did get well, and lived to a good old age. My father had seen many persons who were scalped in East Tennessee, and had there learned from a traveling French surgeon how to treat them. This was to perforate the outer table of the skull with a shoemaker's awl over the whole naked surface, making the perforations very close together. Through these perforations, granulations sprang up and gradually spreading, finally all united and formed a covering to the denuded skull, before it should die and exfoliate, and thus expose the brain. I am sorry that I can not recollect the name of the French surgeon who introduced the practice, for he deserves to have his name immortalized for the great boon he bestowed on the frontier settlers of that day. This operation became, in time, so common that there were persons in every fort who performed it.

While reading this amazing story of frontier hardihood, the phrase "traveling French surgeon" stimulated the present author to search further in the older medical literature, with fascinating results.

Sneve<sup>5</sup> in 1888 noted the above method as described in Eve's *Surgical Cases*, and used it successfully in a case of a burned scalp. In concluding his report he remarks:

To an unknown French surgeon, therefore, belongs the credit of having conceived this most unique procedure. It would be interesting to know whether science or accident were responsible for the conception. A knowledge of the anatomy of the parts and

Experience with Extrapleural Pneumothorax. Harlan F. Newton, M.D., associate in surgery, Harvard Medical School, senior associate in surgery, Peter Bent Brigham Hospital, and John E. ## BOOK REVIEW

*Cancer Its diagnosis and treatment* Max Cutler Franz Buschke. Assisted by Simeon T. Cantor. pp Philadelphia and London W. B. Saunders 1938 \$10.00

This is unquestionably the best book on cancer which has appeared in the last ten years. Since the last edition of Ewing's *Neoplastic Diseases*, there has been a definite need for a text prepared by someone thoroughly familiar with the field of cancer and capable of presenting in straightforward fashion the diagnostic and therapeutic problems.

There is adequate discussion of the principles of radiation therapy, together with some of the hazards involved therein, a very fair appraisal of methods of biopsy, an adequate consideration of the spread of cancer, followed by a series of more or less detailed considerations of various clinical types of the disease. The illustrations are abundant, well selected and clear. The recent literature is adequately considered, and representative groups of statistics are given for the various clinical types of tumors.

myelitis or early complete "agglutination" Their one case report is that of a boy who was treated by Desault by immediate replacement of the scalp. The patient recovered with but slight suppuration at the edges of the replaced scalp. The success of this case influenced their discussion of the subject, and although they discuss the opinions of La Motte, Fr Martel, Felix Wurtz and Cesar Megatus and mention Augustin Belloste as one

his life was recorded in 1778 by Eloy.<sup>9</sup> A translation from the French follows

Belloste, Augustin, was a great surgeon of Paris where he was born in 1654. He served with distinction in the armies and hospitals of the Most Christian King of France, but the Duke Victor Armande de Savoy, King of Sardinia, removed him to his kingdom in 1697 and placed him at the service of the Queen, his mother, in the rank of first surgeon. In 1695 he first published a book entitled *Surgeon of the Hospital, and a Method to Heal Wounds Promptly*, of which there are many different editions. We note those of Paris in 1696 [Fig 1], 1698, 1705 and 1715, in octavo, of Amsterdam in 1707, in octavo, of Dresden in 1703, 1710 and 1724, in octavo, translated into German by Martin Shurig. In 1725 Belloste published *Sequel to the Surgeon of the Hospital*, which appeared the same year in Paris, and again in 1728 in duodecimo editions. In this he combined his important observations on the effects of mercury and the use of this mineral with purgatives. His treatise on mercury was reprinted in 1738 in duodecimo. Denis Sancassani put the whole work into Italian under the title of *The Surgeon in the Field* (Venice 1729), two volumes, in octavo, one may say that it has been translated into almost all the languages of Europe. So many editions and versions amply prove the high estimation in which this book was held. Belloste took from the ancient methods which had been neglected and thereby made a name for himself which is still upheld. It is following Celsus that he advises piercing the carious bone with the point of a trephyn to accelerate exfoliation, and from Cesar Magatus that he demonstrated the danger of tampons and frequent dressings in the healing of wounds.

There are some letters of this surgeon in the works of Sancassani, who speaks of him with great respect. He was also respected by the public for his success in the practice of his art, and he still enjoyed a brilliant reputation when he died at Turin on July 15, 1730.

Belloste<sup>10</sup> in 1696 wrote as follows

If the bone is uncovered for a considerable extent, with loss of substance, the wound cannot heal for a long time because of its size, and one is not able to prevent the bone from becoming altered and carious, by whatever precautions that might be taken. Now in order to avoid this accident it is necessary at the first dressing, or as soon as possible, to pierce the bone in several places with the pyramid or perforator of the trephyn, in this manner one gives passage to a marrow juice which, oozing out, covers the bone in a short time without loss of the least part of its substance.

To be a surgeon, one should know that whenever the bone is uncovered for a considerable area, it is impossible for the soft parts to regenerate without recourse to the Art [of surgery], because the surface is very smooth and polished. It is this fact which obliged most of the ancients to apply the rasp to make it rough and at the same time to open the orifices of the small vessels, of which the internal substance is filled, in order to furnish the blood which is necessary to produce new flesh which heals it.

But the operation which I have done on several occasions and which I propose here seems to me more prompt, sure and useful than the rasp, which while passing several times over the surface of the uncovered

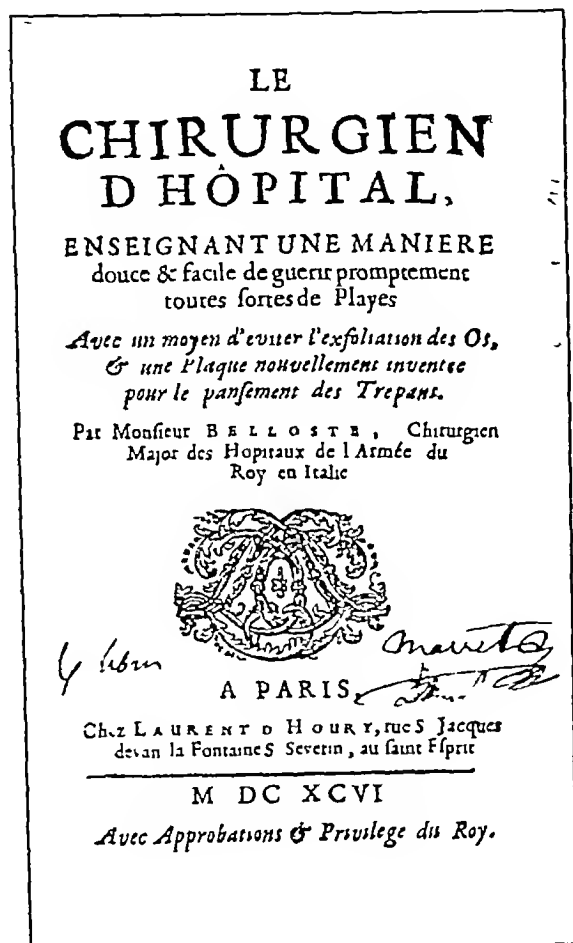

FIGURE 1

Title page of Belloste's book, 1696 containing his account of an operation for avulsion of the scalp. Author's copy.

who practiced multiple perforations, they minimize the deep concern of the older writers over the exfoliation of the denuded cranium and Belloste's method of avoiding it. This attitude was apparently that of most surgeons.

Biographically, Belloste has enjoyed the favor of the more delightful and obscure medical historians. None of the major historical writers have mentioned him in the role of contributor to medical progress. An almost contemporary account of

the physiologic laws governing the reproduction of tissues could have suggested to him the operation, and on the other hand clinical observations of granulations springing from an exposed diploë might have done so. The knowledge of this procedure seems to have been lost after a time, as there are no records that I can find of its having been resorted to on the frontier during the last 40-50 years, though numerous instances have occurred of individuals who have been thus mutilated by the Indians and recovered with bare crania.

Curiously enough, Dr Sneve's article is the only one referring to Eve's book and the report as given in the *Nashville Journal of Medicine and Surgery* which I encountered in going through the literature. This present communication is largely an answer to all his speculations concerning the "unknown French surgeon" and his knowledge.

A search of all the literature under the subject of avulsion of the scalp, wounds of the scalp or scalping, as found in the Surgeon General's Library, the *Index Medicus* and *Quarterly Cumulative Index*, led me no nearer to the truth. Invariably the references to the origin of the procedure—and it is very pertinent to note that two German articles are included—lead to the article written by Dr Felix Robertson<sup>3</sup> and published by the *Philadelphia Medical and Physical Journal* in 1806, when he was twenty-five years of age.

III Remarks on the Management of the Scalped Head. By Mr James Robertson of Nashville, in the State of Tennessee. Communicated to the Editor by Felix Robertson, M.D., of the same place.

In the year 1777, there was a Doctor Vance about the Long Islands of Holsten [located in the Tennessee River] who was there attending on the various garrisons, which were embodied on the then frontiers of Holsten, to guard the inhabitants against the depredations of the Cheerake Indians. This Doctor Vance came from Augusta County in Virginia. In March of the same year, Frederick Calvit was badly wounded, and nearly the whole of his head skinned. Doctor Vance was sent for and staid several days with him. The skull bone was quite naked, and began to turn black in places, and, as Doctor Vance was about to leave Calvit, he directed me, as I was stationed in the same fort with him, to bore his skull as it got black, and he bored a few holes himself to show the manner of doing it. I have found, that a flat pointed straight awl is the best instrument to bore with, as the skull is thick and somewhat difficult to penetrate. When the awl is nearly through, the instrument should be borne more lightly upon. The time to quit boring is when a reddish fluid appears on the point of the awl. I bore at first, about one inch apart, and, as the flesh appears to rise in those holes, I bore a number more between the first. The flesh will rise considerably above the skull and sometimes raise a black scale from it, about the thickness of common writing paper. It is well to assist in getting off the scales of bone with the awl. These scales are often as large as a dollar and sometimes even twice as large.

It will take, at least two weeks from the time of boring for it to scale. When the scale is taken off at a proper time, all beneath it will appear flesh like what

we call proud flesh, and as if there was no bone under it.

The awl may, at this time, and indeed for a considerable length of time, be forced thru the flesh to the bone without the patients feeling it, but after any part has united to that portion of the scalp, which has remaining original skin, it becomes immediately sensible to the touch.

The scalped head cures very slowly, and if this kind of flesh rise, in places, higher than common, touch it with blue stone water, dress it once or twice a day, putting a coat of lint over it every time you dress it, with a narrow plaster of ointment.

It skins remarkably slow, generally taking two years to cure up.

In the year 1781 David Hood was shot, at this place, with several balls, and two scalps were taken off his head, and these took off nearly all the skin which had hair on it. I attended him bored his skull and removed from almost the whole of his head, such black scales as I have described above. It was nearly three or four years before his head skinned over entirely, but he is now living and well.

In 1789, Richard Lancaster and Joel Staines were both wounded, scalped, and left for dead. These persons were under my directions, and their heads were bored as above described. They both got well in the course of 2 years.

M Baldwin, and some others, were scalped either in the year 1790, or 1791. Their skulls I also bored or directed it to be done. They all recovered.

I never knew one that was scalped and bored as above described that did not perfectly recover. There is always part of the scalped head over which but little or no hair afterwards grows.

In 1769 I saw a young man in South Carolina, who had been scalped eight years before that time and about twice the size of a dollar of the bone of his head was then perfectly bare, dry and black. I am persuaded that had this skull even then been bored he might have recovered of the wound which put an end to his life about a year after I saw him, the naked portion of bone having rotted or mortified, and exposed the substance of his brain, a very considerable quantity of which issued out at the opening, at his death. Nashville, — April 10th, 1806.

Patrick Vance, although mentioned in this article, seems not to be remembered by modern writers. There is another record<sup>6</sup> of the procedure which I obtained through a descendant of Vance's.<sup>7</sup> From this document we learn that Patrick Vance was appointed third surgeon with the pay of assistant at Camp Lady Ambler on October 20, 1776, in the Christian campaign, which was commanded by Colonel William Christian, who was ordered to Long Island (of Holsten, Tennessee) with a force of men and reinforced by detachments under Colonels William and Love and Major Winston of North Carolina.

In Bérard and Denonvilliers's textbook of surgical technic,<sup>8</sup> published in 1851, there is a section on the treatment of wounds of the scalp with denudation of the cranial bone. As a first principle these writers state that if the scalp is re-covered, replacement may be followed by osteo-

for those who wished to take a medical degree half a century earlier. The number of graduates is not however an indication of the number of students, for, while many men who studied medicine at Edinburgh took the qualification of the College of Surgeons, right up to the passing of the Medical Act in 1858, a large number of students were content to learn their profession as apprentices to some practitioner and to take a few classes at some medical school such as Edinburgh without proceeding to qualification.

In Boerhaave's *Aphorisms*<sup>18</sup> we find

249 If the Pericranium, or Hair Scalp be so much wounded that it discovers the Bone for a long while or that it putrefy, the Bone is deprived of the Vessels of the Periosteum and consequently of its own, the Liquor is then stagnate, and, being putrefied, separateth a Scale, after which, the Bone, grown yellow, dusky and black, doth deposit a Leaf. 252 The Cure is effected 1 By piercing the Bone as deep as its Middle with a little Trepan, applied to several but near adjoining Places, whereby Exfoliation is prevented and the Periosteum is made to grow again. 253 By which Method there ariseth out of all these Perforations and from all Sides in a small Time, as it were, a new fleshy Substance and afterwards the Rest heals.

Van Swieten<sup>12</sup> in his commentaries on the aphorisms of Boerhaave gives Bellosté full recognition for stating the above, especially does he emphasize that it is a primary and not a secondary procedure. He also records Bellosté's two case reports.

Bellosté's significant contribution was to state that small perforations of the outer table should be made at the primary dressing of the wound, thus entirely avoiding exfoliation or sequestration. The method has been used by modern authors

Here, then, is the story of a definite surgical procedure which, so far as can be found, originated with one man, Augustin Bellosté, in 1696, passed from Boerhaave to Patrick Vance, and carried into modern literature through the medium of two Americans—Felix and James Robertson. No other authors have ever claimed to have thought of the method independently. This is a very peculiar sequence of events, which has combined to preserve for us one small bit of surgical lore. Others even more valuable must have been lost. Such are the vagaries of history.

bone, heats and alters it much more than the perforator which touches but lightly, at slight intervals from each other, and which penetrates far enough to reach the diploë from which one draws the help we need. Moreover, the rasp diminishes the thickness of the bone, and subjects the patient to pain, which one avoids by this operation.

The bone of the cranium takes its nourishment from three separate sources, according to the opinion of several authorities. Firstly, from its under surface or internal portion, which is next the brain, through the vessels of the dura mater. Secondly, from the central part which is between the tables, it is nourished by a marrow juice which, arising from the diploë, communicates to the two tables and furnishes them the necessary food. Thirdly, on its external aspect it is nourished and protected by the periosteum by which it is covered for its entire extent.

Thus when by some outside violence the bone is scalped of this, so that it remains uncovered, it is well assured that the air attaches itself to the external surface with its acid and nitrous points, which in a short time alter and decay it, it is necessary then that it exfoliate because it is deprived of nourishment and the air finds it without defense.

It is then necessary to find a means of repairing the loss to the bone and to find in the neighboring parts food which takes the place of that lost, and which at the same time in covering it shelters it from external injuries. Such cannot be found closer than in the diploë, but to have it, a passage must be made and open to it easy pathways to fulfill at the same time the intention of Nature and that of the surgeon. When the bone is opened as described above, the diploë pushes through these little passages the most subtle parts of its marrow juice, which, coagulating in the bone in three or four or five days, sometimes more or less, completely cover it.

One will have a little hesitation in using this technique if one realizes that it avoids about forty days before exfoliation and the time thereafter necessary to granulate and cicatrize the ulcer, all told taking the poor patient almost sixty days in place of twelve or fifteen at the most following this method.

Belloste then records the cases of two soldiers with moderate-sized wounds which required eighteen and seventeen days respectively for healing.

There are a number of interesting sidelights which turned up in the older literature. Jacobus Renatus Tenon,<sup>11</sup> for whom Tenon's capsule of the eye is named, took a very active interest in Belloste's idea, indeed so much so that he used a number of dogs as subjects of observation in controlled experiments. He denuded both sides of the skull and perforated the outer table on one side with a trephine about the size of a "12 sous piece." Various dressings then in vogue were applied to both sides, such as, water, wine, balsam of Peru, basilicum, *plâtre de mastique*, *l'eau mercuriale*, and in some animals the skull was exposed to the air. His final conclusion was that perforation did not aid healing of the wound enough to justify its use. However, the size of his opening, which caused excessive formation of granulation tissue,

was larger than either Vance or Belloste advised. Let us observe that the publication of these results was in the year 1806, the same as that in which Robertson's<sup>3</sup> account was published in Barton's journal.

The writers of the older books of surgery (Hippocrates,<sup>12</sup> Galen,<sup>12</sup> Celsus<sup>13</sup> and Fabrice d' Aquapendente<sup>14</sup>) knew that baring the calvarium of periosteum was a severe wound and that the outer table often became carious, finally either exfoliating or causing an osteomyelitis, sometimes fatal. Celsus advised the perforation of the dry, blackened sequestrum with an awl or terebra some time after the injury. Fabrice, following Galen's practice, recommended rasping the denuded cranium. All these writers deferred action until delineation between sequestrum and normal bone had occurred. One curious and questionable case, reported by de Marchettis,<sup>15</sup> and antedating Belloste, was that of a seven-year-old boy from the orphanage at Batavia who had his scalp torn off by a bear. Granulations arose from between the sutures and covered the head in fifteen days, and in three months the entire wound was healed and hairs were even growing in the scar.

The problem then resolved itself into the necessity of explaining why the only link between modern literature and the old textbooks should be through but one man, Patrick Vance. None of the nineteenth-century English or American texts on surgery contain any reference to the procedure. Perhaps the authors knew of it but regarded it as of no account.

From a descendant of Dr. Vance,<sup>7</sup> it was learned that his full given name was Kilpatrick. He was born in Scotland and claimed to be a graduate of the University of Edinburgh. It is not known when he came to this country. A letter<sup>10</sup> from the dean of the School of Medicine of the Royal Colleges, Edinburgh, who made inquiries in the Library of the College of Physicians there, states: "There is no evidence that he ever took the qualification here, and his name does not appear on the list of graduates in Edinburgh, Glasgow or Aberdeen." However, Comrie's *History of Scottish Medicine*<sup>17</sup> states that most of the men who founded the Royal College of Physicians and the Faculty of Medicine at Edinburgh were graduates of French universities or had studied under Boerhaave at Leyden, and that Boerhaave's books were used extensively as texts for the students at the time when Kilpatrick Vance was presumably studying there.

Comrie further states

During the latter half of the eighteenth century Edinburgh was the great medical resort of all Britons beyond the seas, much as Leyden had been the resource

stances with dispatch, clamors impatiently for an answer from the worker in biological sciences as to the value and significance of his compounds. Before the final answer as to the therapeutic efficacy of a chemical substance can be given, however, numerous questions have to be answered, and the answer to each requires repeated and tedious investigation. To ascertain the relative efficacy, toxicity and persistence of action under various routes of administration is merely a beginning. Long-continued experiments must follow the short ones. The biological characteristics of the compound should be ascertained in many species of animals and often in lower organisms. There follows a search to determine the physiological and pharmacological effect on various tissues, organs and systems. Eventually as many of these features as is feasible have to be investigated in normal man. Finally, it is necessary to study the effects and biological characteristics of the compound in different diseases. Because the experimental therapeutic approach in diseased persons is limited, it is also essential to study the effect of an agent in disease induced in animals. After encouraging preliminary investigations, a drug may fail to be useful simply because one of its many biological characteristics is not in accord with the therapeutic problems of the specific disease for which it was intended. A vasodilator substance, for example, may fail to be useful in a certain disease simply because it has to be given intravenously or because it has only a short persistence of action. Obviously, with all the investigative opportunities available, it is feasible to supply answers to all these questions for but a limited number of substances. Hence, whereas the chemist can prepare a substance rapidly, medicine must give the answer slowly. It is sometimes discouraging to find that long years of world-wide clinical application of a chemical substance are necessary before its serious untoward reactions are discovered. I refer to such examples as amidopyrine, causing agranulocytosis, cinchophen, producing acute yellow atrophy of the liver, codeine, responsible for drug addiction, arsphenamine causing blood dyscrasias, and phenobarbital (Luminal) or allyl-isopropyl-acetyl-carbamide (Sedormid), causing serious skin rashes.

If a chemical substance reveals a certain biological action which makes it a possible but not an ideal therapeutic agent, attempts are often made to alter the chemical structure with an expectation, rational from a biochemical viewpoint, of obtaining the desired action. Not infrequently, however, the answer supplied by the experimental and clinical studies is different from the theoretical expectation. Such experiences further

strengthen the need for prolonged investigation.

A few specific examples bearing on such recent activities in this field will make these points clearer. Let us consider, therefore, three groups of substances as illustrations: barbiturates, sympathomimetic drugs and the morphine group.

#### BARBITURATES

Thirty-five years ago Emil Fischer and von Mehring established the fact that while barbituric acid, a derivative of urea and malonic acid, is physiologically relatively inactive, the substance obtained by replacement of the two hydrogen atoms by ethyl radicals is a powerful hypnotic in animals and man (Fig 1). Since this discovery a

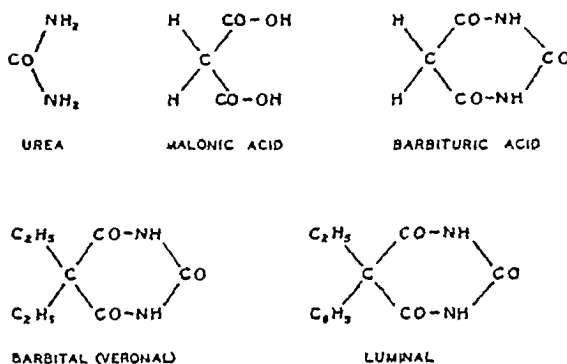

FIGURE 1 The Chemical Structures of Urea, Malonic Acid and Barbituric Acid Which Possess No Hypnotic Effect, and of Their Ethyl and Phenyl Derivatives, Veronal and Luminal

large number of other barbituric acid derivatives have been prepared by replacing one or both hydrogen atoms by alkyl, cyclic and other radicals. Partly through their beneficial effect in certain conditions and partly through the zeal of manufacturing houses, these substances have become widely used in different branches of medicine. The barbituric acid derivatives are certainly among the most widely used drugs today. Veronal, Luminal, Ipral, Amytal, Allonal, Dial, Pernocton, Somnifen, Nembutal and Evipal are but a few of the trade names of the more commonly used barbituric acid derivatives.

A number of significant facts have been brought to light as a result of these studies. It has been found that often the hypnotic value and the toxicity of members of the group have been increased by substitution of the two hydrogen atoms by longer and more complex alkyl or cyclic radicals. The anesthetic value was found to be relatively higher in the ethyl iso-butyl, the ethyl normal butyl, the ethyl-iso-amyl and the ethyl normal hexyl barbituric acids.<sup>1</sup> Investigation revealed also remarkable differences in the excretion of the

## CHEMICAL STRUCTURE BIOLOGICAL ACTION THERAPEUTIC EFFECT\*

SOMA WEISS, M.D.†

BOSTON

THE discussion of the inter-relation between chemical structure, biological action and therapeutic effect seems to be timely. Research activities in fundamental and applied sciences continue to increase. The question is being raised whether universities should take part in these varied activities or restrict their interests to the cultivation of selected disciplines. As a further complication, an increasing number of research institutes have been established in recent years by foundations and by industrial corporations. What is to be the future role of these institutions? Should the less well-equipped university departments, in order to avoid duplication, intentionally cultivate a more fundamental type of investigation and more general correlations? Should there be any sort of inter-relation between university departments and these research institutes? Should industrial research laboratories be used for the temporary training of a limited number of mature students in science, in the same manner as the clinic is used for medical students? Whatever the final answer, we must be cognizant of these changing activities, which are of potential significance.

The question has also been raised by those who are interested in these problems and who are trained primarily in chemistry, as to whether the biological sciences and clinical medicine, in particular, are not unduly lagging behind chemistry. One branch of the biological sciences, namely pharmacology, has been particularly criticized. The correct appraisal of this question is a primary concern of those associated with a medical school.

I shall confine this discussion to an analysis of one phase of this topic.

By citing a few selected examples, I propose to supply an explanation for the following conclusions: (1) Notwithstanding skepticism, important progress has been made in recent years in the field of knowledge which depends on the proper integration of chemistry, certain medical sciences and therapeutics. (2) While from a theoretical point of view there exists an ideal method of correlation of activities between these fields,

in practice important advances and discoveries often fail to follow such a set pattern. (3) As most human ailments cannot be reproduced in animals, and as disease often represents not only quantitative but also qualitative change in functions and structures, study of the action of chemical substances in human disease remains an essential discipline. If today this field is not cultivated in the right way, it does not mean that the subject cannot be made a branch of science. (4) There are good reasons why progress in the chemical aspects of the biological sciences, particularly pharmacology and therapeutics, will always lag, at least apparently, behind chemistry. (5) While this field of activity is cultivated by all branches of chemistry and medical sciences, proper emphasis on and better correlation of the subject in the future may lead to progress of both theoretical and practical significance. Let us now examine these points in greater detail.

The reason for the apparent lag of the chemical aspects of biology and medicine is clearer today than it was formerly. Organic chemistry and biochemistry are relatively young. Pharmacy and therapeutics, on the other hand, are considerably older. Many significant discoveries in therapeutics were made, on purely empirical basis, many years or even centuries ago. The use of opium for the relief of pain and diarrhea, of cinchona bark in malaria, of coca leaves for relief of fatigue, of cod-liver oil and certain fruits in nutritional deficiencies, of iron in anemia, of digitalis in heart failure and of ephedra twigs as a stimulant are examples of such early therapeutic discoveries.

With the development of organic chemistry, toward the end of the nineteenth century, there were those who expected that the application of this new field to medicine not only would at once open up new avenues in pharmacy but would rapidly lead to discoveries of new cures for disease. Some of the therapeutic discoveries and the rapid initial development of experimental pharmacology at the beginning of the present century seemed to confirm and enhance such an optimistic expectation. Certain results during the past two decades, on the other hand, have injected skepticism into the rapid triumph of organic chemistry in medicine.

The chemist, who continues to prepare sub-

Presented before a Harvard Medical School colloquium November 10 1938.

†Associate professor of medicine Harvard Medical School director Second and Fourth Medical Services (Harvard) Boston City Hospital.

in an important way on therapeutic applications. Already Barger and Dale have noted differences in pressor effects of various members in the capacity of ergotoxin to inhibit the vasopressor effects and in causing relaxation of the isolated, non-pregnant uterus of the cat.

The sensitivity of biological responses to slight chemical changes is strikingly illustrated by the difference in the potency between levo- and dextro-epinephrine. Pressor responses to a given dose of l-epinephrine are much greater than those induced by the corresponding d-isomer. The duration of the response is more prolonged, on the other hand, in the case of the d-isomer. It may be pointed out here that the ratio of the muscular contracting power to the relaxing power of the d- and l-epinephrines is not definitely known, in spite of the fact that epinephrine has been investigated extensively. This illustrates the fact that certain pertinent and obtainable knowledge is still lacking, even in such an extensively studied and important substance.

Chen has pointed out that the phenolic groups in the epinephrine molecule are responsible for the intensity of action. With the entrance of a methyl group in the  $\alpha$  carbon atom, ephedrine appears to acquire increased duration of action. Chen found that the primary amines are more active than the corresponding methylated secondary or tertiary amines, especially with reference to pressor action (Chen, Wu and Henriksen<sup>3</sup>).

Figure 2 demonstrates the chemical structure of a few of the sympathomimetic substances. While all these compounds possess vasopressor effects, they differ in several important ways. Catechol, for example, in contrast to other sympathomimetic drugs, exerts a convulsant and cardiac depressor action (Taunter<sup>4</sup>). Epinephrine and nor-epinephrine differ mainly in that ergotoxin reverses the pressor response to epinephrine, but not that of nor-epinephrine. Nor-epinephrine has a greater intrinsic power of inducing contraction of certain smooth muscle cells than has epinephrine. Epinephrine, on the other hand, has a much greater intrinsic power of inducing relaxation. Nor-epinephrine is suspected by some (Greer, Pinkston, Baxter and Brannon<sup>5</sup>) to be one of the adrenergic mediators of sympathetic nerve impulses, corresponding to sympathin E of Cannon and Rosenbluth<sup>6</sup>.

The differences in effect of epinephrine and ephedrine consist mainly in the effectiveness of ephedrine after oral administration, in contrast to that of epinephrine. The vasopressor and cardiac stimulant effects of ephedrine are much less intense but more prolonged. Ephedrine is a less efficacious bronchorelaxant agent, but it possesses a

remarkable stimulating effect on certain brain centers, which makes its action, in contrast to that of epinephrine, quite specific in certain conditions associated with sleep or coma, including narcolepsy.

The two synthetic compounds of amphetamine (Benzedrine) and paredrinol (Veritol) possess interesting pharmacological and therapeutic qualities. In its structure and action amphetamine is closer to ephedrine, while paredrinol resembles epinephrine. Amphetamine exerts less vasopressor, cardiac and bronchial effect, but has a greater central effect than does ephedrine. It has a remarkable action in decreasing or abolishing the sensation of fatigue. Its central stimulating effect makes it particularly suitable in the treatment of narcolepsy and in certain types of paralysis agitans.

Paredrinol is a compound with mainly vascular effect and without significant central nervous action. In contrast to amphetamine it is ineffective in narcolepsy. In contrast to epinephrine, it produces prolonged vasoconstriction after oral administration. The vasoconstriction involves both the arterioles and venules, but arteriolar constriction is not out of proportion to the elevation of the blood pressure. Tissue ischemia, observed after epinephrine, does not occur as a rule after the administration of paredrinol. From both experimental and clinical considerations, paredrinol seems to be a suitable therapeutic agent, while epinephrine is not applicable in certain types of collapse and shock.

#### MORPHINE GROUP

Advances in knowledge in this group of alkaloids are also instructive in the light of what has been said in the introduction to this discussion. Morphine is one of the most useful drugs. In China the use of opium dates back as far as the recognition of cholera there. The stalk of the poppy plant is mentioned as an ingredient of an Egyptian prescription in the *Papyrus Ebers*. The juice of the poppy was certainly an effective remedy in the hands of physicians of ancient Greece. Pliny was probably the first to use the word "opium". During the centuries immediately following, some progress was made in the effective use of opium preparations. The first milestone in this field, however, came with the contributions of the young German pharmaceutical apprentice Sertürner, who in a series of reports published between 1805 and 1817 described the isolation and certain pharmacological characteristics of morphine. Thereafter, as a result of the development of organic chemistry, experimental pharmacology and clinical medicine, valuable information was acquired concerning the chemistry and the biological action of morphine and certain related compounds.

various derivatives. Thus from 60 to 90 per cent of diethylbarbituric acid (Veronal) is eliminated through the kidneys, while other barbiturates are almost completely destroyed within the body. Marked differences have also been found in the persistence of action of the various members. Barbital (diethylbarbituric acid) and Luminal (phenobarbital) have a persistence of action of many hours' duration, while the effect of Evipal (cyclo-hexamyl-methyl-n-methyl barbituric acid) lasts but a few minutes after intravenous administration. In the latter substance we possess a hypnotic with a complex side radical. This side chain is instantly metabolized in the body, and thus a biologically active compound is changed into one which is inert. The time element of induction of sleep also varies considerably. The sleep induced by some barbiturates is preceded by excitement, while others do not produce this effect.

If we wish to use a sedative as a preventive of convulsions in epilepsy, we use a barbiturate with long persistence of action, such as phenobarbital, in small doses. If we wish to combat severe convulsions we use the same type of barbiturate in large amounts. If we wish to induce natural sleep we select members with shorter persistence of action, in order to avoid a hang-over the next day. Pentobarbital sodium (Nembutal) and iso-amyl-ethyl barbituric acid (Amytal) are such barbiturates. If prompt anesthesia and relaxation of the muscles are desired, as in the treatment of fractures or dislocations, we administer Evipal intravenously and obtain the desired result for but a few minutes.

Studies of the barbiturates, particularly during the last ten years, have enriched medicine by providing a group of useful drugs which are administered in the treatment of insomnia, poisoning from local anesthetics, epilepsy, pain in childbirth and eclampsia. These drugs are also useful for the better induction of general surgical anesthesia. Today we have also adequate knowledge of the danger involved when barbiturates are used in large amounts, or when they are administered to persons with an idiosyncrasy to certain members of the group. We know that certain barbiturates are responsible for skin diseases and blood dyscrasias. In case of barbiturate poisoning, effective antidotes have been found in drugs such as picrotoxin, ephedrine and strychnine. Thus after making due allowance for unsupported claims, the accomplishments make the investigations of the past more than justified.

#### SYMPATHOMIMETIC DRUGS

It is fitting to discuss here the sympathomimetic group of drugs, not only because of their wide-

spread therapeutic use, but also because this group is of considerable significance to chemists, physiologists and pharmacologists in developing an understanding of the relation between chemical constitution and biological action.

Achievements in this field are the result of varied and quite independent investigations. Our knowledge is based on the discovery of a vaso-pressor effect of extract of the adrenal by Oliver and Schafer and by Czybulsky and Symonovicz in 1895. Takamina's discovery of crystalline epinephrine in 1901 stimulated interest in the chemistry of this substance. Barger and Dale's classical study in 1910 on the relation between the chemical structure of aliphatic and aromatic amines and their sympathomimetic activities established important chemopharmacological principles. More recently, efforts to identify chemically the "adren-

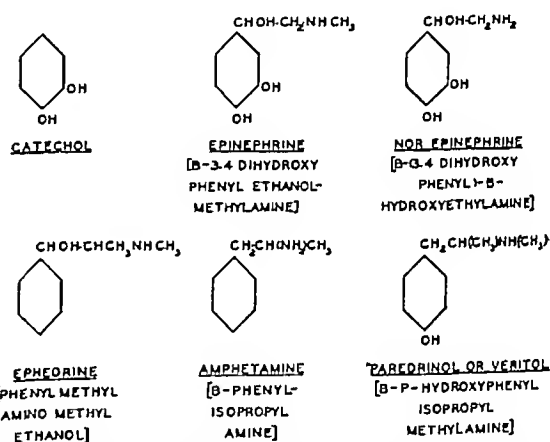

FIGURE 2 The Chemical Structures of Some of the Sympathetic Amines with Biological and Therapeutic Actions

ergic" mediators of nerve impulses have injected a new stimulus into this field, mainly as a result of the work of Cannon, Loewy, Bacq and Rosenblueth.

Meanwhile, quite independently, Chen and others<sup>2,3</sup> have studied a number of alkaloids isolated from the ancient Chinese remedy ma huang. These alkaloids also turned out to be sympathomimetic aromatic amines, related in their chemical structure and pharmacological action to ephedrine. Finally, attempts have been made by chemists to prepare new compounds, with the expectation of obtaining agents with more desirable action.

These groups of sympathomimetic amines have as their prototype l-epinephrine, which consists of a catechol nucleus to which aliphatic side chains are attached, in which alcoholic and amine groups are substituted (Fig 2). The number of known related amines is great, and possible chemical variants are unlimited. These different amines exert different biological actions, some of which bear

in an important way on therapeutic applications. Already Barger and Dale have noted differences in pressor effects of various members in the capacity of ergotoxin to inhibit the vasopressor effects and in causing relaxation of the isolated, non-pregnant uterus of the cat.

The sensitivity of biological responses to slight chemical changes is strikingly illustrated by the difference in the potency between levo- and dextro-epinephrine. Chen found that the primary amines are more active than the corresponding methylated secondary or tertiary amines, especially with reference to pressor action (Chen, Wu and Henriksen<sup>3</sup>).

Figure 2 demonstrates the chemical structure of a few of the sympathomimetic substances. While all these compounds possess vasopressor effects, they differ in several important ways. Catechol, for example, in contrast to other sympathomimetic drugs, exerts a convulsant and cardiac depressor action (Tainter<sup>4</sup>). Epinephrine and nor-epinephrine differ mainly in that ergotoxin reverses the pressor response to epinephrine, but not that of nor-epinephrine. Nor-epinephrine has a greater intrinsic power of inducing contraction of certain smooth muscle cells than has epinephrine. Epinephrine, on the other hand, has a much greater intrinsic power of inducing relaxation. Nor-epinephrine is suspected by some (Greer, Pinkston, Baxter and Brannon<sup>5</sup>) to be one of the adrenergic mediators of sympathetic nerve impulses, corresponding to sympathin E of Cannon and Rosenblueth<sup>6</sup>.

The differences in effect of epinephrine and ephedrine consist mainly in the effectiveness of ephedrine after oral administration, in contrast to that of epinephrine. The vasopressor and cardiac stimulant effects of ephedrine are much less intense but more prolonged. Ephedrine is a less efficacious bronchorelaxant agent, but it possesses a

remarkable stimulating effect on certain brain centers, which makes its action, in contrast to that of epinephrine, quite specific in certain conditions associated with sleep or coma, including narcolepsy.

The two synthetic compounds of amphetamine (Benzedrine) and paredrinol (Veritol) possess interesting pharmacological and therapeutic qualities. In its structure and action amphetamine is closer to ephedrine, while paredrinol resembles epinephrine. Amphetamine exerts less vasopressor, cardiac and bronchial effect, but has a greater central effect than does ephedrine. It has a remarkable action in decreasing or abolishing the sensation of fatigue. Its central stimulating effect makes it particularly suitable in the treatment of narcolepsy and in certain types of paralysis agitans.

Paredrinol is a compound with mainly vascular effect and without significant central nervous action. In contrast to amphetamine it is ineffective in narcolepsy. In contrast to epinephrine, it produces prolonged vasoconstriction after oral administration. The vasoconstriction involves both the arterioles and venules, but arteriolar constriction is not out of proportion to the elevation of the blood pressure. Tissue ischemia, observed after epinephrine, does not occur as a rule after the administration of paredrinol. From both experimental and clinical considerations, paredrinol seems to be a suitable therapeutic agent, while epinephrine is not applicable in certain types of collapse and shock.

#### MORPHINE GROUP

Advances in knowledge in this group of alkaloids are also instructive in the light of what has been said in the introduction to this discussion. Morphine is one of the most useful drugs. In China the use of opium dates back as far as the recognition of cholera there. The stalk of the poppy plant is mentioned as an ingredient of an Egyptian prescription in the *Papyrus Ebers*. The juice of the poppy was certainly an effective remedy in the hands of physicians of ancient Greece. Pliny was probably the first to use the word "opium". During the centuries immediately following, some progress was made in the effective use of opium preparations. The first milestone in this field, however, came with the contributions of the young German pharmaceutical apprentice Sertürner, who in a series of reports published between 1805 and 1817 described the isolation and certain pharmacological characteristics of morphine. Thereafter, as a result of the development of organic chemistry, experimental pharmacology and clinical medicine, valuable information was acquired concerning the chemistry and the biological action of morphine and certain related compounds.

various derivatives. Thus from 60 to 90 per cent of diethylbarbituric acid (Veronal) is eliminated through the kidneys, while other barbiturates are almost completely destroyed within the body. Marked differences have also been found in the persistence of action of the various members. Barbitol (diethylbarbituric acid) and Luminal (phenobarbital) have a persistence of action of many hours' duration, while the effect of Evipal (cyclo-hexamyl-methyl-n-methyl barbituric acid) lasts but a few minutes after intravenous administration. In the latter substance we possess a hypnotic with a complex side radical. This side chain is instantly metabolized in the body, and thus a biologically active compound is changed into one which is inert. The time element of induction of sleep also varies considerably. The sleep induced by some barbiturates is preceded by excitement, while others do not produce this effect.

If we wish to use a sedative as a preventive of convulsions in epilepsy, we use a barbiturate with long persistence of action, such as phenobarbital, in small doses. If we wish to combat severe convulsions we use the same type of barbiturate in large amounts. If we wish to induce natural sleep we select members with shorter persistence of action, in order to avoid a hang-over the next day. Pentobarbital sodium (Nembutal) and iso-amyl-ethyl barbituric acid (Amytal) are such barbiturates. If prompt anesthesia and relaxation of the muscles are desired, as in the treatment of fractures or dislocations, we administer Evipal intravenously and obtain the desired result for but a few minutes.

Studies of the barbiturates, particularly during the last ten years, have enriched medicine by providing a group of useful drugs which are administered in the treatment of insomnia, poisoning from local anesthetics, epilepsy, pain in childbirth and eclampsia. These drugs are also useful for the better induction of general surgical anesthesia. Today we have also adequate knowledge of the danger involved when barbiturates are used in large amounts, or when they are administered to persons with an idiosyncrasy to certain members of the group. We know that certain barbiturates are responsible for skin diseases and blood dyscrasias. In case of barbiturate poisoning, effective antidotes have been found in drugs such as picrotoxin, ephedrine and strychnine. Thus after making due allowance for unsupported claims, the accomplishments make the investigations of the past more than justified.

#### SYMPATHOMIMETIC DRUGS

It is fitting to discuss here the sympathomimetic group of drugs, not only because of their wide-

spread therapeutic use, but also because this group is of considerable significance to chemists, physiologists and pharmacologists in developing an understanding of the relation between chemical constitution and biological action.

Achievements in this field are the result of varied and quite independent investigations. Our knowledge is based on the discovery of a vasopressor effect of extract of the adrenal by Oliver and Schafer and by Czybulsky and Symonovicz in 1895. Takamina's discovery of crystalline epinephrine in 1901 stimulated interest in the chemistry of this substance. Barger and Dale's classical study in 1910 on the relation between the chemical structure of aliphatic and aromatic amines and their sympathomimetic activities established important chemopharmacological principles. More recently, efforts to identify chemically the "adren-

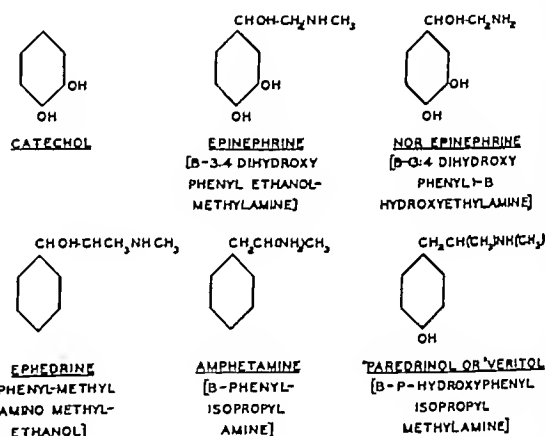

FIGURE 2 *The Chemical Structures of Some of the Sympathetic Amines with Biological and Therapeutic Actions*

ergic" mediators of nerve impulses have injected a new stimulus into this field, mainly as a result of the work of Cannon, Loewy, Bacq and Rosenbluth.

Meanwhile, quite independently, Chen and others<sup>2,3</sup> have studied a number of alkaloids isolated from the ancient Chinese remedy ma huang. These alkaloids also turned out to be sympathomimetic aromatic amines, related in their chemical structure and pharmacological action to ephedrine. Finally, attempts have been made by chemists to prepare new compounds, with the expectation of obtaining agents with more desirable action.

These groups of sympathomimetic amines have as their prototype l-epinephrine, which consists of a catechol nucleus to which aliphatic side chains are attached, in which alcoholic and amine groups are substituted (Fig 2). The number of known related amines is great, and possible chemical variants are unlimited. These different amines exert different biological actions, some of which bear

treatment of abdominal distention) in patients with myasthenia gravis has yielded new insight into muscular physiology and pathology. Similarly, the empirical discovery of the therapeutic value of quinine in myotonia congenita has stimulated physiological studies on the striated muscles.<sup>9</sup> The casual clinical observation that a high-fat diet, devised for the treatment of epileptic children, has resulted in a rapid clearing up of co-existent pyelonephritis instigated a systematic investigation of the bactericidal effects of various organic acids. These studies in turn led to the important discovery of the value of mandelic acid in the treatment of certain types of pyelonephritis.

\* \* \*

Here, then, is a field of great significance for the future development of medicine. It should be cultivated in the future not less but more than in the past. If physicians are to maintain an interest not only in analytical but also in synthetic activities, they must foster more intensely this triple interest of correlations. Such increased knowledge

will give better insight into the secrets of life, and at the same time will assure better care of the sick. Therapeutic skill must depend not on an innate, intangible gift, but rather on a rational analysis and definition of the patient as a psychophysical unit, and on a knowledge of the possibilities as well as the limitations of those physical, chemical and abstract measures which improve or re-establish health.

## THE TREATMENT OF TETANY WITH DIHYDROTACHYSTEROL (A T 10)\*

LEWIS M. HURXTHAL, M.D.,<sup>†</sup> BOSTON, AND  
T. STERLING CLAIBORNE, M.D.,<sup>‡</sup> ATLANTA, GEORGIA

IN 1936, when dihydrotachysterol first became available in this country, we were fortunate in obtaining a supply for trial in the treatment of parathyroid tetany.\* It at once became obvious that it caused an elevation of blood calcium toward normal and adequately controlled the symptoms of tetany. Being effective by oral administration, it promised to be the most convenient and effective method of controlling severe tetany. We immediately encountered two difficulties. In the first place, the cost of the material made its use undesirable by some patients with mild tetany which could easily be controlled by the oral administration of calcium lactate. Secondly, our doubts as to its value in all cases of severe tetany were raised by an apparent failure to elevate the blood calcium and control symptoms in a very severe case (Case 1), it was later learned that the apparent failure was due to lack of co-operation by the patient.

Dihydrotachysterol is known as A T 10 (antitetanic preparation Number 10), a derivative of

irradiated ergosterin, and is said not to be antirachitic. Introduced first by Holtz,<sup>1</sup> there have been numerous articles on its clinical use since then. Albright and others,<sup>2</sup> through their studies on its effect on calcium-phosphate metabolism, have concluded that A T 10 is the most efficacious therapeutic agent in the treatment of tetany. The reader is referred to their review of the literature for a fuller bibliography.

Vitamin D acts like A T 10 in facilitating calcium absorption from the intestinal tract, but its action is slower and there is less excretion of phosphorus in the urine. Both drugs raise the level of the blood calcium. Parathormone, while raising the blood calcium, is thought by Albright et al.<sup>3</sup> not to have any action on calcium absorption from the intestinal tract, although there is marked phosphorus secretion in the urine. This observation, in addition to the necessity of hypodermic injection, makes parathormone give way to the oral use of A T 10 in the treatment of tetany.

We have used A T 10 in 6 cases of post-operative tetany. All these patients had had tetany for two years or more, so that their status was

<sup>†</sup>Physician in-charge, Department of Internal Medicine, Lahey Clinic, Boston.

<sup>‡</sup>Formerly assistant physician, Lahey Clinic, Boston.

In recent years, after a period of relative stagnation, interest in the field has been renewed. The new tools applied were those of synthetic organic chemistry. These recent efforts consist mainly in the preparation of new compounds through alteration of the morphine and codeine molecules, with the primary purpose of obtaining drugs with some of the therapeutic effects of morphine but without its undesirable effects (Fig. 3).

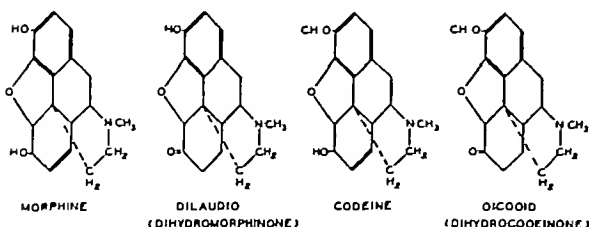

FIGURE 3 *The Chemical Structures of Morphine and of Related Compounds*

Codeine, which is chemically but a slightly altered morphine derivative, a methyl morphine, is about twenty times less toxic than morphine. It is only fairly effective as a therapeutic agent in the control of cough, and but slightly effective in the relief of pain. Up to the present codeine has not been regarded as a drug producing addiction. The story of its discovery as a drug of addiction is mentioned here to demonstrate how long a clinical fact may escape recognition. In 1927 the discovery was made in England that the importation of codeine had increased remarkably and that the drug had to some extent replaced morphine among addicts. In 1931, however, a group of experts appointed by the League of Nations expressed the opinion that codeine was harmless and did not produce addiction. Evidence that the drug was used extensively by addicts nevertheless continued to accumulate. Smuggling of the alkaloid into Canada had become disquieting, and illicit entry across the border into the United States had grown alarmingly. One of the experts mentioned reinvestigated the entire problem, and has called attention to the codeine danger.<sup>7</sup> He refers to experiments performed on animals with habit-forming drugs as more or less valueless. He also points out that there is little or no analogy between monkeys and human beings in their reactions to codeine, while in rabbits and other mammals the alkaloids of opium are apt to give rise to tetanic convulsions.

The biological properties, including the analgesic and respiratory action, of Dilaudid (dihydromorphinone hydrochloride) are quite similar to those of morphine, but Dilaudid is more than twice as toxic, as well as twice as effective. While tolerance to this drug develops less easily than does that to morphine, addiction has been reported

Dilaudid has a certain limited therapeutic use in preference to morphine.

The pharmacological and therapeutic properties of Dicodid (dihydrocodeinone bitartrate) are closer to those of morphine than to those of codeine. Its respiratory-depressant and sedative effects are claimed to be more marked than those of morphine. Its narcotic and analgesic effects are less. Dicodid, in contrast to morphine, does not cause constipation. The tendency to addiction after its prolonged use is less than after morphine.

Numerous additional efforts have been made in recent years to find useful therapeutic agents through changes in the morphine molecule. The practical applicability of the results of these studies cannot as yet be evaluated. In spite of the numerous new compounds which have been prepared and tested, it may be stated that so far no substance in this group with effective sedative or analgesic qualities is known which is not, at least to some degree, associated with a tendency to habit formation and to addiction.

#### OTHER EXAMPLES

This discussion could be widened by presenting numerous additional examples of chemicopharmacological correlations. The choline derivatives are of special interest today, as they play a fundamental role in physiology, pharmacology and therapeutics. Studies of the sulfanilamide group have resulted in therapeutic triumphs in certain infectious diseases. Systematic investigations of carbon tetrachloride, tetrachlorethylene and hexyl resorcinol groups have made possible more effective treatment of parasitic intestinal infestations. Finally, recent discoveries and correlations of the chemistry and biological action of substances related to phenanthren, cholesterol, vitamin D, estrogenic substances and the digitalis glucosides are opening up possibilities for a better understanding and the establishment of an inter-relation between the fundamental problems in the etiology of cancer, in the development of arteriosclerosis, in sex function and in myocardial failure. Perhaps with the development of this new knowledge the most instructive lessons can be drawn from the relation between molecular arrangement, function and cellular structure. This fascinating new chapter in medicine has been admirably summarized by Butenandt.<sup>8</sup>

In several important therapeutic advances the initial discovery and stimulus were provided by observations of the clinician at the bedside. The classic discovery of the efficacy of liver in pernicious anemia has stimulated important chemical investigations. The observation of the beneficial effect of Prostugmin (previously used only for the

well known, and with 2 exceptions were symptomatically controlled with calcium by mouth. Of this group, only 3 patients are still taking A T 10, the remainder having had to discontinue its use because of its high cost. It is hoped that this obstacle will soon be overcome so that it may be available to patients with average incomes.

In several of the milder cases, all calcium by mouth was stopped for from two to four weeks, A T 10 was then begun in doses ranging from 12 to 20 cc during the first four or five days, but thereafter reduced to 1 cc daily or 1 cc every other day. In severe cases calcium was stopped and A T 10 was begun immediately in larger doses, but shortly thereafter 1 to 3 cc daily was prescribed. Later, available calcium in the form of calcium lactate, chloride or gluconate was prescribed orally.

No toxic symptoms were observed except in those cases in which the blood calcium rose above normal. Two patients (Cases 2 and 3) had a hypercalcemia. One of these (Case 2) developed headache and the patient had an extreme aversion to taking the calcium, nausea was also present. The other patient (Case 3) complained of loss of appetite, nausea, headache and lassitude. Both patients soon lost their symptoms when A T 10 was discontinued, one (Case 3) even went through pregnancy without additional medication. Following delivery the dose was increased, during which time hypercalcemia developed.

The daily requirement of A T 10 apparently depends on the extent of the deficiency. Doses of 2 to 5 cc weekly are sufficient to control the milder moderate cases, while severe cases may require larger doses. Large doses are taken during the first week of treatment, the level of blood calcium is determined at least weekly thereafter. When the blood calcium has reached a normal level, an arbitrary dose of 0.5 to 2.0 cc is prescribed until the daily or weekly requirement is worked out. It is advisable to give calcium by mouth whenever it can be tolerated, as it reduces the amount of A T 10 required and in turn provides soluble calcium. In spite of arguments in favor of other calcium preparations, calcium lactate in our experience has been the best-tolerated form. Blood phosphorus levels have varied. In some cases, particularly when hypercalcemia was present, there was a marked drop, then the blood phosphorus rose again and the calcium dropped. In general, the average blood phosphorus level was lower after treatment. In one patient (Case 4), in whom severe hypertension developed, there was a gradual rise in the phosphorus level although the use of A T 10 was intermittent. In this case its employment in this manner required

less calcium, and there were longer periods of freedom from tetany.

#### CASE REPORTS

*Case 1* A 20-year-old woman entered the clinic December 1, 1936, complaining of 'spells' which had occurred during the previous 10 months after subtotal thyroidectomy had been performed at another institution. These spells were typical of severe tetany and often ended in unconsciousness.

Examination showed that the patient was well developed and nourished. Marked exophthalmos was present, the pulse was 100 and no thyroid remnants could be palpated. The blood pressure was 140/80. The heart and lungs were normal. Chvostek's and Trousseau's signs were easily elicited. The patient entered the hospital 2 days later, at which time the level of the blood calcium was 67 mg per 100 cc, and that of the phosphorus 7.9 mg, two days later the value for calcium was 67 mg, and for phosphorus, 8.6 mg. The patient was given calcium lactate with some improvement and was then started on A T 10 (Fig. 1) but this was discontinued because she said it caused diarrhea. Some months later the patient revealed that she had been taking a large dose of mineral oil which had been secretly given her at the hospital, and which undoubtedly accounted for the looseness of the bowels.

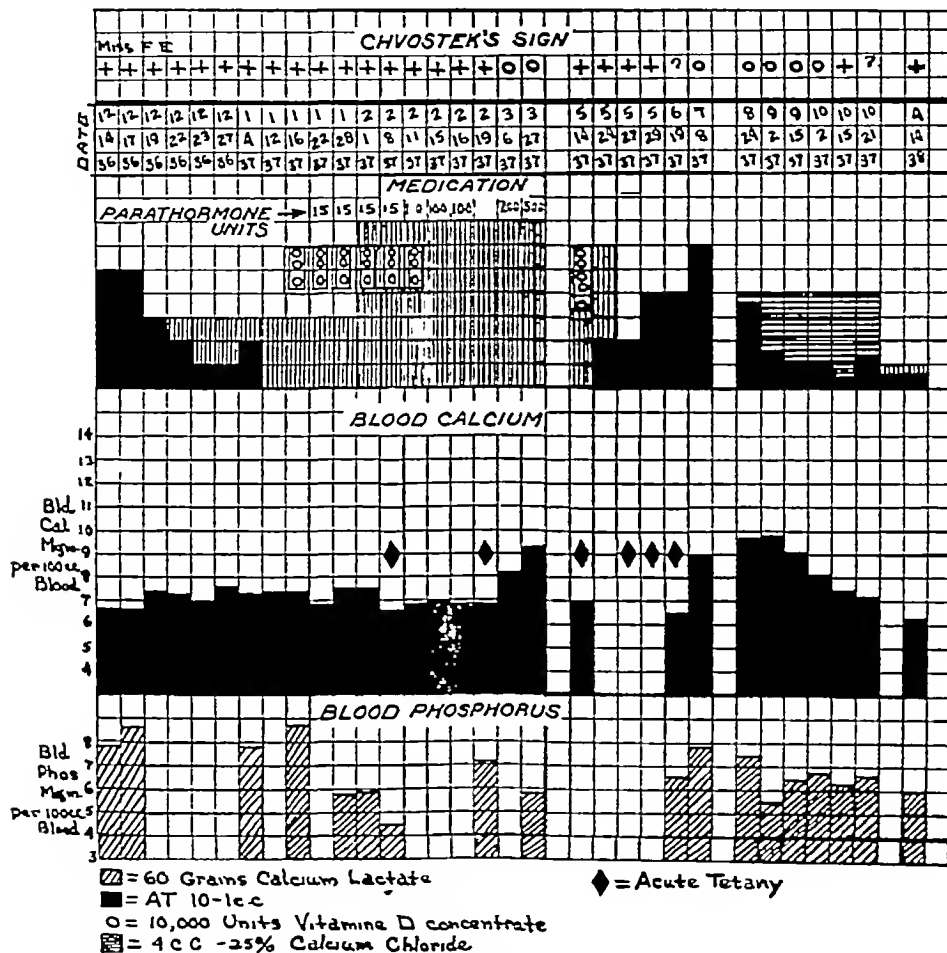

The patient was then given large doses of calcium and vitamin D concentrate. The blood calcium reading in January, 1937, was 81 mg per 100 cc, and that of phosphorus 7.1 mg. Doses of parathormone were gradually increased, and she returned to the clinic with acute tetanic seizures, quickly relieved by intravenous injections of a 10 per cent solution of calcium gluconate. During this time she was given a diet low in milk, meat and eggs, without appreciable effect. In March she was taking 500 units of parathormone a day and said she took from ½ to 1 lb of calcium lactate daily. The value for the blood calcium at this time was 81 mg per 100 cc, and she was getting along fairly well. On March 29 the blood calcium reading was 9.3 mg per 100 cc, and that of the phosphorus 5.9 mg. The patient continued on this regime, and in May entered the clinic with another attack of acute tetany. She had had several of these attacks while in neighboring cities. At this time she was taking 50,000 units of vitamin D, 300 to 400 units of parathormone and 10 teaspoonfuls of calcium lactate in powder form and ten 10-gr tablets of calcium lactate daily. Calcium chloride was again advised, but she could not tolerate it. From May 27 to July 1 the tetany was never adequately controlled and she had frequent attacks. All during this time Trousseau's and Chvostek's signs were positive. A T 10 in larger doses was begun, in addition to parathormone and large quantities of calcium. A blank space has been left in the chart for an interval during which the amounts of parathormone and calcium that were ingested are unknown, on one occasion during this period she was ordered to take 20 to 30 cc. of A T 10 daily for a few days. On July 14 the blood calcium was 8.9 mg and the phosphorus 7.1 mg per 100 cc, and Chvostek's sign was positive. On July 23 she was advised to take 15 cc. of A T 10 daily. On August 4 the level of the blood calcium was 9.9 mg and that of the phosphorus 4.1 mg per 100 cc, Chvostek's sign was negative and she was feeling well, being free from tetany. She was advised to reduce the dose to 7 cc. a day, the case was followed until September, the dose being cut down gradually to 4 cc. and 1 teaspoonful of calcium chloride four to six times a day. The value

for the blood calcium remained normal, Chvostek's sign was negative, and dosage was further reduced to 1 cc. and then to 0.5 cc. daily. The blood calcium gradually fell to approximately 7 mg per 100 cc., and the patient was advised to increase the dose to 1 cc. daily for an indefinite period.

The patient was not seen again for some months. When seen in April, 1938, she said she had not taken A T 10

normal, and following this she obeyed instructions explicitly. She has also assured us that she took the prescribed quantities of calcium and parathormone.

*Case 2* The patient, a 28-year-old unmarried woman, was first operated on in the clinic in 1918 for exophthalmic goiter. In 1921 there was a recurrence of hyperthyroid symptoms. Lugol's solution was given but failed to control the symptoms, and in 1931 she was operated on be-

FIGURE 1 *Case 1*

*Control of severe tetany with AT 10* The dosage from December 14 1936 to March 27, 1937 is the amount ordered but as mentioned in the text the amount taken is uncertain. The period from March 27 1937 to May 14 1937, is omitted because of the uncertainty of dosage the patient being away at this time. Larger doses of AT 10 than those given subsequently were ordered during this period. The blood calcium August 24 1937 was normal while the patient was daily taking 3.5 cc of AT 10. Note the gradual fall of blood calcium as the dose of AT 10 was diminished. The latter figures are probably reliable.

or calcium regularly, the blood calcium had dropped to a little more than 6 mg per 100 cc., Chvostek's sign was positive and there were minor tetanic symptoms.

*Comment* Although this patient refused to co-operate, it is to be noted that the value of her blood calcium was normal for the first time and remained normal on a daily dose of about 1.5 cc. of A.T. 10. Although we cannot prove it, the patient assures us that she actually did take the required dosage at the time her blood calcium was

cause of recurrence of the hyperthyroidism. Following this a low metabolic rate developed, without much clinical evidence of myxedema. At the same time she had mild tetany. The blood calcium varied between 6 and 7 mg per 100 cc. This was easily controlled by administration of calcium and parathormone. In 1935 the patient had a transplant of parathyroid tissue culture (Fig 2), with no lasting benefit, although it seemed that for about two or three weeks she was able to get along without calcium

and with no symptoms of tetany. Since that time the patient has controlled her tetany easily with calcium lactate, taking about 5 teaspoonfuls daily. At other times she was given 40 drops of viosterol without much apparent help. The value for the blood calcium ranged from 8 to 9 mg per 100 cc. In 1936, A.T. 10 was started and the calcium was discontinued. The blood calcium rose to slightly over 10 mg per 100 cc. Treatment was continued intermittently until April 8, 1937. At this time she was taking about 120 gr of calcium lactate by mouth

over 4 mg A.T. 10 was discontinued, and the patient's blood calcium returned to a normal level in about one week. Her symptoms disappeared. Since that time the patient has been taking 0.5 cc. three times weekly with 60 to 120 gr of calcium lactate daily.

*Comment.* This patient seemed to get along satisfactorily without any unusual rise in blood calcium on 0.5 cc. of A.T. 10 daily. She was advised to return more frequently for a check up examination and for determination of blood calcium but neglected to do so, and without

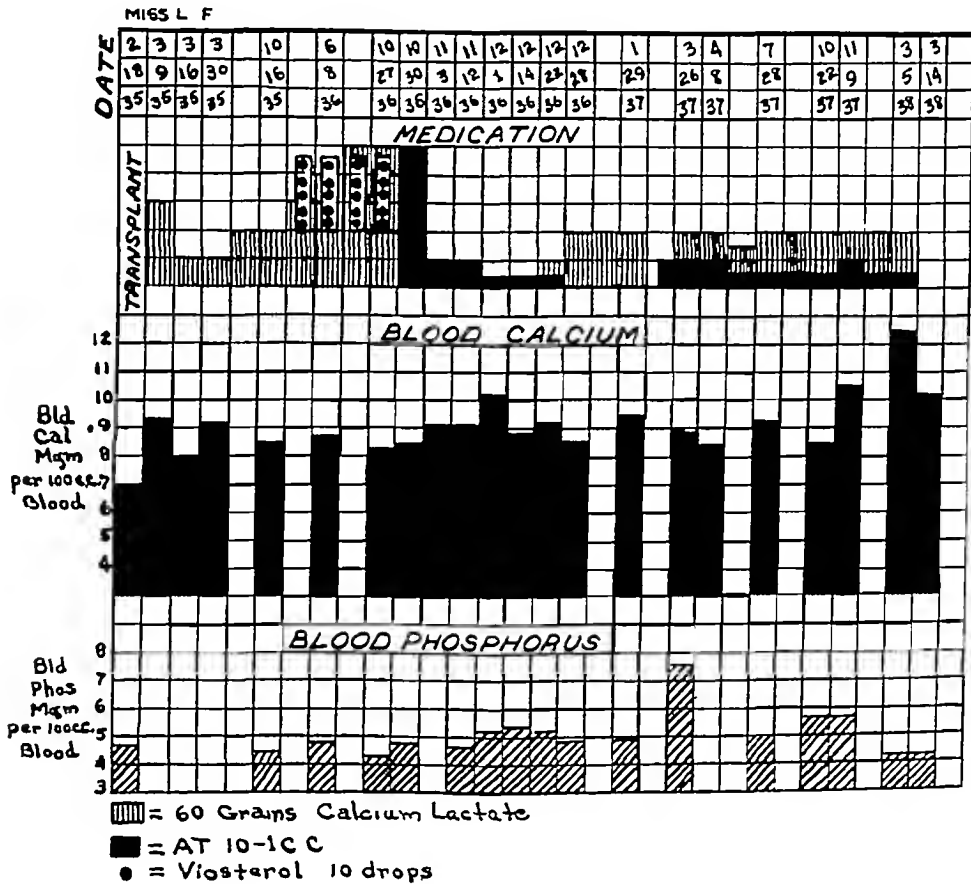

FIGURE 2 Case 2

*Control of mild tetany with AT 10 and development of hypercalcemia.* The value for the blood calcium on February 18, 1935 was 7 mg per 100 cc after the patient had been ordered not to take calcium for some time preceding a transplant of parathyroid tissue culture. On October 30, 1936 AT 10 was begun and calcium by mouth was omitted. The level of the blood calcium finally rose to 10 the highest it had ever been. From November 9 1937, to March 5, 1938, the patient took approximately the same amount of calcium daily, with 0.5 cc of AT 10. On March 5 1938 symptoms associated with hypercalcemia were present

and 0.5 cc. of A.T. 10 daily. This kept her free from symptoms although the level of blood calcium averaged between 8.5 and 9 mg per 100 cc. For a short while in November the patient took 1 cc. of A.T. 10 a day and then reduced the dose again to 0.5 cc. daily. She continued this until March 6, 1938, before coming in for a check up examination. At this time she reported because she felt ill. She had nausea and vomiting, loss of appetite, headaches, pain in the eyes and stated that she never wanted to see calcium again as long as she lived. The blood calcium at this time showed definite hypercalcemia, the level being 12.4 mg per 100 cc., the blood phosphorus was slightly

increasing the dose, hypercalcemia resulted. This illustrates the necessity for frequent determinations of blood calcium. This patient could easily get along without AT 10, since the tetany could be controlled with calcium lactate, but she preferred to take it, stating that she has fewer ups and downs when so doing.

*Case 3.* This 26-year-old woman entered the clinic in February, 1935. She had had a subtotal thyroidectomy elsewhere in July, 1928, following which she immediately showed evidence of parathyroid tetany which was partially relieved by giving calcium and thyroid extract.

Since then she had complained of stiffness in her fingers. Six months following operation the patient had a convulsion during which she became unconscious for about fifteen minutes. From that time until her admission to the clinic she had had four such attacks. At the onset of these attacks the patient cried out, fell and often injured herself. The last attack occurred one week before her admission.

The patient came to us mainly to find out if it were safe for her to be married because the grandmother of her fiance had had similar seizures.

was again given and also A.T. 10 in a dose of approximately 3 cc. a week. Pregnancy progressed without complications, but on this dose, without taking calcium, the level of blood calcium fell from 9.1 to 7.8 mg per 100 cc. She was then given more calcium, and the dose of A.T. 10 was increased to 1 cc. a day for a month before delivery. She had no further trouble and gave birth to a normal, healthy child. The patient was given calcium gluconate intravenously just before delivery and the doses of calcium and A.T. 10 were increased for a few days after delivery,

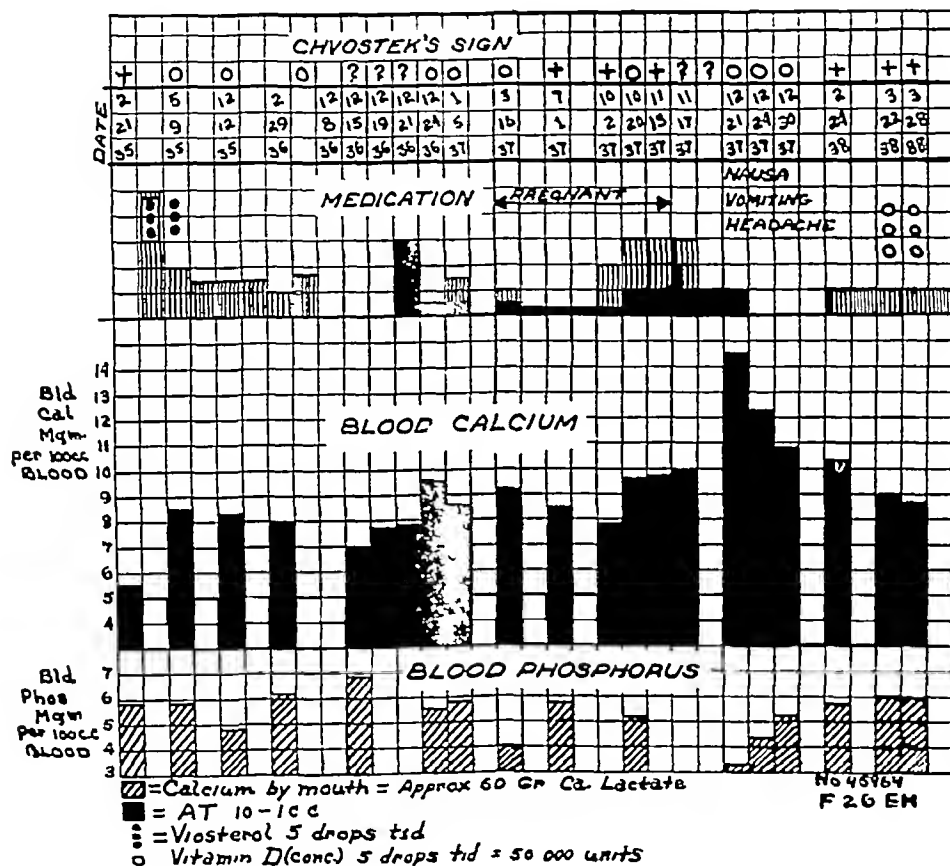

FIGURE 3 Case 3

Course during pregnancy of a patient with tetany, taking A.T. 10, subsequently hypercalcemia developed. The blood calcium determinations and dosage of A.T. 10 are shown in solid blocks. Note the level of the blood calcium on December 24 1936 after A.T. 10 was begun also the gradual drop of blood calcium during pregnancy with 0.5 cc of A.T. 10 daily. Note also the high level of blood calcium which developed one month after delivery while the patient took 1 cc daily with no calcium by mouth. Of interest is the low value for the blood phosphorus at this time.

The level of blood calcium was found to be 5.7 mg per 100 cc, and that of the blood phosphorus 5.8 mg (Fig 3). She was given viosterol and calcium lactate, this therapy raised the level of the blood calcium and her symptoms were immediately controlled. On December 8, 1936, all calcium was discontinued for a period of eleven days. The blood calcium averaged 7.5 mg per 100 cc., her fingers felt stiff, and her face tingled. A.T. 10 was then given, 3 cc. the first day and 0.5 cc. daily thereafter, with a rather prompt rise in the value for the blood calcium to over 9 mg per 100 cc. She discontinued A.T. 10 and resumed calcium until she became pregnant. Calcium

with the idea of preparing her for nursing her child. When she left the hospital the level of the blood calcium was 10 mg per 100 cc., and she was advised to continue with 1 cc. of A.T. 10 daily. She failed to come in for over a month at which time nausea, vomiting and headache developed. The blood calcium was found to be 14.3 mg per 100 cc. The blood phosphorus was very low, and as A.T. 10 was discontinued, the value for the blood calcium fell toward a normal level and the blood phosphorus returned to its previous level. Since that time the patient has been on calcium lactate by mouth and vitamin D concentrate, equal to 50,000 units of vitamin D daily. This

has kept her symptoms controlled, the blood calcium has varied between 8.5 and 9 mg per 100 cc. It would seem that during pregnancy, on a dose of approximately 3 cc. of A.T. 10 weekly, the blood calcium gradually fell.

**Case 4** This 42-year-old woman was operated on elsewhere in 1917 for exophthalmic goiter. She was first seen in the clinic in 1926 and said that she had had severe tetany ever since her operation. She had been treated with calcium and other preparations but had never been free from tetanic seizures. Merely rising suddenly from a chair would throw her into severe cramps. She suffered frequently from laryngeal spasm. From 1926 until 1936 she was treated in the clinic with calcium and, at times, parathormone. She had two transplants without permanent effect, one, a transplant of a parathyroid tumor from a patient with hyperparathyroidism, and the other, a transplant of a parathyroid tissue culture. For about a month after each operation her symptoms were ameliorated. She was started on A.T. 10 on November 20, 1937, 3 cc. was given daily for five days, and then 1 cc. daily thereafter. Calcium was discontinued. At the time A.T. 10 was started, the level of the blood calcium was 9.3 mg per 100 cc., and that of the blood phosphorus 8.3 mg. Only calcium lactate had been administered before this blood sample was taken. This, incidentally, was the highest value for blood calcium which had been recorded for some time. Before treatment was begun in the clinic her blood calcium had varied between 4.5 and 5.6 mg per 100 cc., and at the time of the tissue-culture transplant, when she was allowed to go without calcium, the blood calcium went down to 4.8 mg and the phosphorus to 6.3 mg. The patient continued with A.T. 10 until December 5, 1937. During that time she had taken no calcium by mouth and the blood calcium was reported to be 9.3 mg per 100 cc., and the blood phosphorus 8.3 mg.

The patient felt much better, and on December 19 she had had no spells whatsoever and was taking 1 cc. of A.T. 10 daily. The value for the blood calcium at this time was 9.5 mg per 100 cc. The dose was reduced to 0.5 cc. daily, which she continued to take until January 2, 1938, when the blood calcium was 8.6 mg, and the blood phosphorus 5.2 mg. She continued to have no further attacks and took no calcium. On January 25 the blood calcium reading was 7.7 mg, and the phosphorus 5.5 mg, and she was advised to take calcium lactate again, a heaping teaspoonful three times a day. In April, 1938, the blood calcium was 8.6 mg, and the phosphorus, 4.8 mg. She was taking 0.5 cc. of A.T. 10 every day and a level teaspoonful of calcium lactate three times a day. In June, 1938, the first seizure appeared. The blood calcium levels at this time were 8.5 mg and 6.8 mg on two separate occasions. From that date until December, 1938, she was not able to purchase A.T. 10, and the blood calcium gradually fell to 7.6 mg, with further seizures. Since then she has resumed A.T. 10 with complete relief and the blood calcium is maintained above 9 mg per 100 cc. Her blood pressure has gradually risen until, when last seen, it was 210/140, the blood nonprotein nitrogen was 24 mg per 100 cc., and the renal output 20 per cent of phenol-sulfonephthalein in 30 minutes.

**Comment** A.T. 10 controlled the symptoms of this patient for the first time in 10 years without calcium, and its effect in this case has been most gratifying.

**Case 5** A 37-year-old woman was operated on in May, 1935, for recurrent hyperthyroidism. Mild parathyroid tetany developed on the day she left the hospital. She was given 60 gr of calcium lactate a day. The level of the blood calcium was 5.7 mg per 100 cc. Chvostek's sign was positive. Viosterol (15 drops a day) was administered. Later she said that she had received parathormone on several occasions. Her symptoms finally were fairly well controlled on 3 heaping teaspoonfuls of calcium lactate, three times a day, and 20 drops of viosterol. The value for the blood calcium was 7.5 mg per 100 cc., and that of the blood phosphorus 4 mg.

On December 15, 1936, the blood calcium was 7.1 mg and the phosphorus 3.8 mg. Calcium was discontinued and A.T. 10 started, 5 cc. the first day and 5 cc. the second day, then 3 cc. for several days and finally 1 cc. daily. She did not take calcium, and when seen two weeks later the blood calcium was 7.4 mg, and the phosphorus 4.8 mg, she felt improved.

In January, 1937, the calcium was 8.9 mg per 100 cc., she was taking 1 cc. of A.T. 10 daily. In June, 1938, the blood calcium was 8 mg, and the phosphorus 3.6 mg, she had been taking 1 cc. daily. The patient has also taken  $\frac{1}{2}$  gr of thyroid extract daily. She has never taken calcium since using A.T. 10 but has been advised to do so. We have been able to follow her through the courtesy and co-operation of Dr. Charles J. Ashwarton, of Providence, Rhode Island.

**Case 6** This 32-year-old woman was first seen in February, 1926. Operation was performed for exophthalmic goiter in July, 1926. Tetany after operation was controlled with calcium by mouth. The patient was seen October 14, 1936, at which time the value for the blood calcium was 9.3 mg per 100 cc., and that for the blood phosphorus 5.5 mg. She was ordered to take no calcium for 4 weeks, and had few symptoms during that time. Chvostek's sign was positive, the blood calcium was 8.8 mg, and the phosphorus 5.1 mg. She was given A.T. 10, 3 cc. a day for five days, at the end of which time the blood calcium was 9.3 mg, and the phosphorus 5.0 mg. The dose was reduced to 1 cc. daily for five days, when the blood calcium was 10.2 mg, and the phosphorus 4.8 mg. The dose was further reduced to 1 cc. three times a week. The blood calcium then was 9.2 mg, and the phosphorus 5.2 mg, Chvostek's sign was negative. She has been subsequently free from symptoms.

#### CONCLUSION

The use of A.T. 10 is an effective and convenient method of controlling severe tetany. While it is probably desirable to use it in all cases of tetany, milder cases can be controlled symptomatically with calcium lactate.

## THE TREATMENT OF SEVERE CARBUNCLES BY X-RAY

FREDERICK W. O'BRIEN, M.D.\*

BOSTON

THE treatment of inflammatory lesions by x-ray is not of recent origin. Its use, however, in the treatment of carbuncles, either alone or as an adjuvant of surgery, has not been accepted so generally as would seem to be warranted.

Dunham<sup>1</sup> as early as 1916, reporting 67 cases of carbuncle treated by x-ray wrote, "Nothing in all roentgen therapy gives such positive and uniformly perfect results as the treatment of a carbuncle."

This optimism has been shared by roentgenologists these many years, although publication of detailed data on the subject has been infrequent. Coyle<sup>2</sup> in 1906 described 3 cases of carbuncle treated by x-ray. Dunham's cases appeared a decade later. Almost another decade passed before Hodges<sup>3, 4</sup> in 1924 and 1925 stimulated interest anew in the roentgen method of treating carbuncles. Light and Sosman<sup>5</sup> in 1930 analyzed 50 cases treated by x-ray, stating that the addition of the roentgen ray to the therapy of carbuncles gives promise of being perhaps the most valuable innovation of the past century.

Morton and Leddy<sup>6</sup> in the same year compared the results of early and late x-ray treatment of 26 cases, reporting analgesia, abortion and prompt improvement in those treated early. Similar results in 56 cases were observed by Firor<sup>7</sup> and by Whitmore<sup>8</sup> in 1935, the latter reporting 19 cases treated by x-ray, with a review of the literature.

King<sup>9</sup> in 1937 published the results of 33 cases of carbuncle treated by roentgen ray. The locations were as follows: 12 on neck, 8 on face, 4 on axilla, 5 on extremity and 4 on back. Of this series 3 cases were complete failures. Two of these were seen early, but in both the carbuncle was on the back of the neck and of the deep type in which the mass appeared to be fixed. Surgery had to be resorted to in each case. The third failure was in a case previously treated by incision, where evidently the infection had been carried down to the deeper structures by surgical procedure. Filtered radiation King found to be far superior.

Other articles, presenting for the most part generalizations, have appeared, but Light and Sosman's<sup>5</sup> comment on the meagerness of the English and American literature on the value of

x-ray therapy in the treatment of carbuncles still remains pertinent.

Sir James Paget<sup>10</sup> in his clinical lecture on the treatment of carbuncles indicated what is generally recognized today, that a carbuncle is often self-limited and may disappear regardless of the kind of treatment or with no treatment whatever. Incidentally he condemned the use of crucial incision and carrying it beyond the edges into healthy tissue because it did not prevent the carbuncle from spreading. Ordinary carbuncles on the lip and face, he declared, were no more fatal in those situations than in any other. He referred to what he called carbuncular inflammation of the lip or malignant pustule, which he recognized to be more serious than other types, but gave no adequate description of it. This condition probably represents carbuncle of the lip with cellulitis.

When carbuncle is self-limited, convalescence is brief and assured. This may well account for the reputed success of the variety of surgical and non-surgical methods of treatment described. Lest x-ray therapy be included in these "actively useless" measures, as characterized by Paget, carbuncle in the ambulant patient, a lesion that localizes quickly with little or no systemic reaction and no complicating disease, will not be discussed.

There is question here only of severe carbuncle, if you will, an inflammatory lesion that has spread to the subcutaneous tissue, causing a diffuse infection from which toxic absorption has occurred, presenting a fixed area of induration which later discharges on to the surface by a series of openings or massive slough. Each case presented was hospitalized, and had a systemic reaction characterized by fever and an extensive lesion, complicated in many cases by diabetes, and in some by cellulitis, meningitis or septicemia. Others had such accompanying and debilitating conditions as thyrotoxicosis, psychosis, varicose ulcer, compression fracture, subdural hematoma, mid-thigh amputation, carcinoma of the larynx and cardiac disease.

From 1924 to 1937, inclusive, 130 cases of severe carbuncle were treated in the wards of the Boston City Hospital by x-ray alone or in conjunction with surgery. Ninety-five patients were men and 35 women. One hundred and twenty-six patients were discharged well, 4 died, a mortality of 3 per cent.

The lesions were distributed as follows: pos-

\* Professor of radiology, Tufts College Medical School, visiting roentgenologist, Boston City Hospital.

terior neck, 53, upper lip, 28, lower lip, 7, cheek, 16, chin, 6, back, 7, elsewhere, 13

From the viewpoint of radiation, these cases fall naturally into three groups. Group 1 comprises 60 patients who received roentgen therapy only with dry dressings and had an average hospital stay of eight and a half days. Group 2 represents 34 cases given x-ray therapy before surgery, the latter consisting of puncture, crucial incision or excision of slough, the average hospital stay was thirteen days. Group 3 includes 36 cases subjected to surgical procedure before roentgen therapy, with an average hospitalization of twenty-one days.

Dry dressings only were prescribed in Group 1, chiefly in an attempt to evaluate the efficacy of the roentgen irradiation. In the treatment of Groups 2 and 3, heat in the form of a poultice or heating pad was also employed. The average number of x-ray treatments given was three. Either medium- or high-voltage filtered radiation was employed, depending on the character of the lesion or the apparatus available at the moment.

A brief description of the four fatal cases follows.

*Case 470* The patient, a 52-year-old man, was comatose on admission. An upper-lip lesion had been incised at home by his physician. He received one x-ray treatment but died in 72 hours from meningitis.

*Case 711* The patient, a 45-year-old woman, suffering from diabetes, received three x-ray treatments for a carbuncle on the back of the neck, which was incised. Death occurred from septicemia in 7 days.

*Case 904* The patient, a 36-year-old man with diabetes, was admitted with a carbuncle of the scalp, which had been incised at home. He presented an extensive cellulitis and a positive blood culture on admission. He received two x-ray treatments, but died 34 days after entrance from septicemia.

*Case 1638* The patient, a 60-year-old man with diabetes and a posterior neck lesion, entered with a positive blood culture. He received three x-ray treatments, but died of septicemia 27 days after entrance.

Mitchiner<sup>11</sup> analyzed 240 cases of severe carbuncle admitted to St. Thomas's Hospital from 1928 to 1933. He makes no mention of irradiation. There were 13 deaths, a mortality of 6 per cent. Acute pyemia or septicemia was the cause of death in 11 of the fatal cases. It is more likely to occur, Mitchiner states, if surgical interference is undertaken when the carbuncle is spreading or still unlocalized. Eight of the fatal cases he attributed to this error in treatment. There were 10 diabetic patients in his series, an incidence of 4 per cent and 83 patients with facial carbuncles, an incidence of 34 per cent. "No surgical treatment should be attempted under any conditions,"

he writes, "in facial carbuncles or those complicating diabetes."

In the groups here reported there were 16 diabetic patients, an incidence of 12 per cent. There were 9 diabetic patients in Group 1, 4 in Group 2 and 3 in Group 3 with 1 death in each group from septicemia. While the numbers are small, they permit us to draw the general conclusion that carbuncle in patients with diabetes is a major hazard, but to challenge the oft-quoted dictum "In diabetes the treatment of carbuncles by x-ray without surgery is contraindicated."

The reason for conservatism in the treatment of facial carbuncle, especially that of the lip, is well known. This location is notoriously unfavorable because of the ever-present danger of extension of the thrombophlebitic process "in two directions by way of the nasal veins, the superior labial, the angular vein, and its anastomosis with the superior and inferior ophthalmic veins into the cavernous sinus or by way of the anterior facial vein into the general circulation. The resulting cavernous sinus thrombosis, meningitis, brain abscess or septicopyemia are almost always fatal."<sup>12</sup>

There were 57 cases of facial carbuncle in our series, an incidence of 44 per cent. All received x-ray therapy alone except four of the upper lip cases, 1 of which fell in Group 2, and 3 in Group 3, 1 of the latter terminated fatally.

If conservatism should be used in the treatment of carbuncles in this location, one wonders why surgeons insist on the excision of carbuncles elsewhere, blithely dismissing irradiation, when over and over again one sees abortion of many of the early carbuncles and the breaking down and localization of the more advanced lesions following x-ray treatment.

One of the most satisfying effects of the x-ray therapy of carbuncles is the relief of pain. Occasionally it is aggravated for a few hours, but rarely does it persist for more than from three to nine hours. In our series, when the x-ray consultation was early, as in the Group 1 cases, heat in any form was forbidden so as to have a control series. The Group 1 cases affirm the analgesic effect of the roentgenization of carbuncles—a phenomenon well established in other conditions.

Absorption with exudate with little or no scar ring was the rule when roentgen therapy was given early. Arrest in the spread of the infection was commonly observed even when the treatment was given relatively late. It seems important, however, to use x-ray early and in small doses.

There is good experimental evidence for the employment of x-rays in the treatment of infections. It has been repeatedly shown that relatively enormous doses of x-ray are necessary to

render bacterial cultures inert, but that organisms in living tissue are destroyed by small doses

Businco,<sup>13</sup> in a series of experiments performed on dogs inoculated with typhoid bacilli, found that the irradiated abscesses healed within eight days, while the controls took from twelve to fifteen days to disappear. Histologically the favorable action of the roentgen rays resulted in a marked hyperplasia of the connective tissue, forming a mechanical barrier to the infiltrating and necrosing process.

Freund<sup>14</sup> has demonstrated experimentally that inflammatory cells do not migrate to the site of the inflammation but are formed locally from connective tissue cells in the blood vessels. In his cases roentgen irradiation inhibited exudation and decreased the number of inflammatory cells.

Colwell<sup>15</sup> summarizes the modern concept of many investigators of the action of x-ray in inflammatory lesions as follows:

In localized infection a general consideration of the evidence rather points to a response on the part of the reticuloendothelial system than to leukocyte destruction with consequent liberation of antibodies. This is further corroborated by the fact that chronic infections and more acute infections irradiated in their late stages fail to give the best response. If leukocyte destruction were the most important determining factor, a rapid clearing up of the condition might be expected in the chronic cases; the lack of such reaction perhaps rather indicates local exhaustion of the reticuloendothelial apparatus.

A further point is the necessity for small doses of radiation in the treatment of microbial infections and the observation—which seems established—that heavy

dosage inhibits or destroys the protective effect of the reticuloendothelial system.

#### CONCLUSION

A series of 130 hospitalized cases of severe carbuncle treated by x-ray alone or in conjunction with surgery are presented, with a mortality rate of 3 per cent. There was no death in 57 cases of facial carbuncle treated either alone or chiefly by roentgen therapy. There was no evidence that carbuncle in the diabetic patient was a contraindication to x-ray therapy. The 60 cases treated early by x-ray alone had a shorter convalescence than did the others.

465 Beacon Street.

## REPORT ON MEDICAL PROGRESS

## UROLOGY

WILLIAM C. QUINBY, M.D.\*

THE following is a brief summary of the major advances that have been recently made in urology

## PROSTATECTOMY

There are three types of pathologic change which occur in the prostate which cause obstruction to the outlet of the bladder—simple hyperplasia (often called benign hypertrophy), prostatic carcinoma (sometimes combined with hyperplasia), and median-bar obstructions and those due to hyperplasia of the median lobe.

For removal of the simple hyperplasia, enucleation through a transvesical approach (suprapubic prostatectomy) has been widely used for many years. An approach through the perineum (perineal prostatectomy) carries a lower mortality and also makes possible removal of prostatic carcinoma, which is present in about one fifth of all cases. This type of operation has also been standardized throughout many years. For the median-bar and median-lobe obstructions operation through the urethra, in the former by the use of the punch instrument perfected by Young, has been generally very satisfactory. However, because the original instrument made no provision for the control of bleeding, various modifications (Braasch-Bumpus, Thompson) have been produced which employ one form or another of electric current. With the advent of the electro-surgical cutting current this was adapted to a transurethral instrument (McCarthy) by which tissue can be excised with easy control of bleeding. After the perfection of such instruments steps were soon taken to extend their use to cases of prostatic hyperplasia much more extensive than mere enlargement of the median lobe. It was found that this form of operation made few demands on the patient's strength and therefore carried a low mortality. Convalescence also was definitely shortened. Soon transurethral operation was being advocated for all obstructions caused by the prostate regardless of their nature or type. A wave of enthusiasm followed, largely fostered by the industrious over-advertising of instrument dealers, during which many physicians as well as most of the general public were swept off their feet, hoping that this so-called

"new" method, so different from the earlier "cutting operations," was in truth a panacea.

Sufficient time has now elapsed to permit an unprejudiced survey of the whole field, such as has been the subject of two strikingly important communications read at the last meeting of the American Medical Association. The first, by Davis, presents an analysis of a nation-wide inquiry addressed to over a hundred urologists. It should be closely studied by the whole medical profession, for though dealing specifically with transurethral resection of the prostate, it also contains many wise comments on "the reaction of the medical profession to anything new." Davis outlines by the use of a graphic chart the succeeding stages of this apparently characteristic reaction.

Overenthusiasm [he says] inevitably follows the discovery of a new therapeutic agent, particularly that discovery which tends to be startling or which carries with it a dramatic appeal. After overenthusiasm, in varying degree but in definite sequence, come publicity, commercial exploitation, incompetence and abuse, followed by poor results, recognition of defects and dangers, fear, decreased use and overcorrection, until finally such merits as may exist become recognized in their true light and the new therapeutic agent (drug or surgical method) reaches stability at its proper level of usefulness.

Davis's conclusions are of course that removal of the prostate by the transurethral route is far from being a panacea. About 80 per cent of urologists believe in adapting the form of operation to the conditions presented by the patient. "A skillful few, however, rather than fit the operation to the patient have succeeded in fitting the patient to the surgeon."

One point which comes clearly out of a present-day study of the transurethral method is that it is distinctly *not* an operation to be done by the occasional operator, for all good or even passable results depend on a most exact and extensive familiarity with the bladder outlet and the changes caused in it by the various types and forms of prostatic hyperplasia, as well as on a high degree of manipulative skill. Such familiarity and experience can only be acquired by those relatively few urologists who are associated with a large clinic.

The second communication on this subject is that of Hinman. After discussing the three types

\*Clinical professor of genito-urinary surgery, Harvard Medical School; urologist, Peter Bent Brigham Hospital.

of obstruction to urination by the prostate,—median bar, hyperplasia and cancer,—he points out that of the three methods of surgical approach—the suprapubic, perineal and transurethral—the perineal alone enables a logical attempt to be made toward the entire enucleation of malignancy. Since cancer of the prostate is the underlying cause of the prostatism in about 1 case out of every 5, a strong argument in favor of the perineal approach exists. As to the relative claims of each of the three methods of attack, Hinman says that the suprapubic approach is suitable for hyperplasia, and is rarely if ever used for removal of a median bar or for cancer except unintentionally when the neoplasm is concealed within hyperplasia. The surgical risk is high, the mortality being between 4 and 20 per cent, with an average of 8 per cent. The period in the hospital is relatively long—from thirty to forty days. As a rule the functional results are both good and permanent.

The perineal operation is difficult to master, and the functional risk in the hands of the inexperienced surgeon is high. The hospital stay averages twenty-one days. The risk is low, the mortality being between 1 and 8 per cent, with an average of 3 per cent. Also, this is the only operative approach which results in the cure of cancer.

The transurethral approach, according to Hinman, is most popular and its greatest fault lies in its very popularity. The mortality varies from 1 per cent in the hands of the expert to as high as 30 per cent or more. The average mortality is probably about 4 per cent. Even when the operation is well done, recurrence is frequent, and of course no attempt is made by this procedure to control cancer.

At the clinic of the Peter Bent Brigham Hospital we have been convinced for at least a decade that the approach to the prostate through the perineal route is by far the most logical one, and is followed by the best results as regards both function and mortality. Especially is this true in cases in which the prostate is carcinomatous, for when the gland is thus exposed, accurate judgment of the extent and position of the malignancy becomes possible. Because of the customary late recognition of prostatic cancer it is often impossible to excise all the malignancy, even by a total prostatectomy. But by the entirely adequate exposure through the perineum it is always possible to free the outlet of the bladder by excision of the growth in this region, after which radon seeds can be used in those areas which cannot be removed. Progressive growth of the carcinoma after such a palliative operation is often quite slow, patients not infrequently retaining good general

health and a satisfactory bladder function for from two to four years.

The transurethral operation in our hands has been confined for the most part to benign median-bar and middle-lobe obstructions and to benign hyperplasias of lateral and median lobes of such size that a complete enucleation of all hyperplastic tissue seemed possible at a single operative session. It has been well recognized, ever since the earlier days in which the electrocautery of Bottini was used, that the removal of tissue in the floor of the prostatic urethra in the form of a gutter or groove is entirely inadequate; the bladder cannot be completely emptied, infection persists or increases and the patient is not cured. Therefore a transurethral attack on a hyperplastic obstructing prostate cannot be conscientiously adopted by the surgeon unless he is certain that he will be able to remove practically all the hyperplastic tissue. It is largely due to a lack of appreciation of this need that we have seen so many poor results after an attempted resection through the urethra. For to remove the necessary amount of tissue of the larger glands requires an extensive and complete familiarity with the prostatic portion of the urethra and the changes in its appearance caused by the hyperplasia. This demands good vision at all stages of the operation, to be obtained only by adequate control of bleeding. The Braasch-Bumpus punch, seen in its latest form in the instrument of Thompson, is doubtless the best in that there is no devitalized or cauterized tissue left after operation to act as a frequent cause of late bleeding on the separation of the sloughs. The proper use of this instrument requires much practice, however, especially by those surgeons who have not had experience in vision through an instrument devoid of lenses. The McCarthy instrument, in which the cutting is done by an electric current of high frequency, is easier to use on the whole, but because the character and modalities of the electric current with its especial generator must be accurately adjusted, one finds only too often difficulty in controlling bleeding or in cutting cleanly without causing cauterization and its attendant dangers from secondary hemorrhage.

Everyone familiar with the present developments of the transurethral operation must appreciate that in spite of its failures and shortcomings in the past, it represents in proper hands today one of the outstanding accomplishments of urology. In reality, the only remaining difference in opinion lies in the decision as to what types of obstructing prostate should be so attacked. This aspect would seem to be most adequately covered by the summary of Davis above quoted, in which

it was found that the large majority of surgeons practice careful selection of the cases which in their hands seem suited to transurethral surgery

In summary, therefore, present-day opinion may be stated as follows

(1) Suprapubic prostatectomy is technically simple. It is probably the only type of operation which should be undertaken by the occasional surgeon. Its mortality is higher than after other types of operation, and the convalescence longer, but its results in general are both good and permanent.

(2) Perineal prostatectomy is technically exacting on the surgeon but less so on the patient. It should not be undertaken without a detailed familiarity with the anatomy of the perineum, which can be acquired only by extensive experience. Its mortality is very low, and it is the only route by which carcinoma can be adequately controlled. It is the operation of choice in many clinics.

(3) The transurethral operation, though seemingly simple, is in reality harder to execute than either of the other forms when applied to obstruction by the prostate caused by factors other than hypertrophy of the middle-lobe or median bar. Its indiscriminate use has doubtless done much harm, which to some extent has obscured its real worth. It entirely omits from consideration the important and frequent cases of prostatic cancer. A second operative session is quite often necessary. The procedure carries a very low mortality and short convalescence, but its results are invariably poor unless all or nearly all the hyperplastic tissue is removed and hemostasis is accurately and completely obtained. In order to achieve this result an extensive training is imperative.

#### UNILATERAL RENAL DISEASE AND HYPERTENSION

The association of various forms of renal disease with general circulatory hypertension has long been of much interest to clinicians. Intrinsic renal disease of a diffuse type, as in vascular nephritis and pyelonephritis, is commonly accompanied by hypertension at some period in the progress of such disease. The general belief in the past, however, has been that a bilateral renal abnormality must exist in such cases. Recently work which has accumulated from experimental laboratories has demonstrated beyond question that arterial hypertension can be produced in animals by various methods which interfere with the renal blood supply of only one kidney. The most generally successful method has been that of Goldblatt, who has devised a clamp by which partial constriction of the renal artery can be made. As a result of the ischemia produced by such a clamp

a persisting hypertension appears, even though one kidney is allowed to remain normal. Following removal of the occluding clamp or excision of the kidney so treated, the blood pressure returns to normal.

This is not the place to undertake a discussion of the considerable volume of work which has been devoted to this subject, nor of the present attempts to describe the cause of the hypertension so produced. The important aspect for the urologist lies in the clear demonstration of the fact that such hypertension can be present even in unilateral renal disease. For if cases of this kind are to be found in the clinic, it is fair to assume that cure of the vascular manifestations may follow a nephrectomy. This has in fact been found to be so, and during the past year several papers have been published in which such cases are described. Leadbetter and Burkland's case was that of a colored boy of five and a half years who had had hypertension from the age of six months. There was enlargement of the heart and an ectopic right kidney, without evidence of infection. The average blood pressure was about 152 systolic, 90 diastolic. There were no abnormalities of the eye grounds. After nephrectomy, at which the ectopic kidney was found alongside the right iliac artery, the blood pressure fell immediately to 125 systolic, 92 diastolic, and after discharge it was 96 systolic, 70 diastolic. Examination of the kidney showed no evidence of infection, but the lumen of the renal artery was almost occluded by a tissue plug made up of smooth muscle, considered by the authors to represent an anomaly of development.

Six cases of hypertension in the presence of unilateral renal lesions of the infective type are related in the communication of Crabtree. In all there was hypertension which fell noticeably after nephrectomy. Boyd and Lewis report a further case in which the blood pressure became normal after nephrectomy for renal infarct.

It appears that in view of this undoubted close relation between certain renal conditions and the phenomena of general vascular hypertension, all patients should be investigated by detailed urological methods before being subjected to any one of the various forms of surgical operation designed to relieve their hypertension, such as sympathectomy, section of anterior nerve roots and adrenal denervation.

#### RENAL INFECTIONS

Progress in the control of renal infections has been made along several lines during the last year or two. It is generally known today that each case of infection must be closely studied in order

to determine and remove the source or cause of such infection if possible. Of equal importance is the demonstration of the presence or absence of any factor in the urinary tract which may act to cause stasis. Only after removal or correction of such mechanical cause can one hope to combat successfully the attendant infection. For instance, it is practically impossible to bring about sterilization of the urine when a kidney bears a stone, or when the stone lies in the ureter and thus causes stasis in the passages above it. After such a mechanically obstructing cause has been removed or proved to be absent, the infection can be fought by one or another of the various antiseptic substances, especially mandelic acid or sulfanilamide. Also, it is to be again emphasized that the criterion of cure of any urinary infection should always be a sterile culture of the urine drawn under aseptic precautions, for it has been shown repeatedly that the absence of pus cells and of symptoms is not enough. Treatment must be continued till the urine is sterile, in order to avoid recurrence.

In a recent article Braasch discusses this subject. He first notes the three types of pyelonephritis. The first (the so-called "acute pyelitis" of earlier days), coming as an acute attack of relatively short duration, is very common, possibly standing next in frequency to the infections of the respiratory tract. He writes

The medicine we give these patients is often given credit for clearing up infection which in reality has been overcome by natural resistance. However, when the infection persists longer than four or five days and when it is accompanied by fever and chills, nature is materially aided by the administration of any of the various chemotherapeutic agents now available.

The second type is characterized by recurring attacks of acute infection lasting possibly several weeks and reappearing after variable lapses of time. In practically all such cases, though the patient seems well, the urine does not become sterile between attacks, and some mechanical condition in the urinary tract which induces stasis may be present.

The third type of pyelonephritis is its chronic form. Braasch includes under this heading those cases in which the infection has persisted for at least a year and in which, with rare exception, both kidneys are involved. He notes that when only one kidney is found to be infected over a long period of time, a secondary complication should be assumed, usually requiring surgical treatment. Though some patients may acquire a relative im-

munity to such infection, in others secondary complications are common, such as stone formation, hematuria or pyonephrosis due to a cicatricial deformity.

Of the two drugs today most potent in fighting such infections, mandelic acid is of most use in infections caused by *Streptococcus faecalis*. This drug is usually only effective when the urine is made highly acid by the administration of ammonium chloride, and this condition may be difficult or impossible to bring about. Sulfanilamide is particularly efficient in combating urinary infections due to the colon bacillus and the proteus bacillus. Braasch believes that there is no doubt that sulfanilamide and its derivatives have already reduced the occurrence of chronic pyelonephritis and even bid fair to eliminate it. He finds that large doses of sulfanilamide are frequently unnecessary in infection of the urinary tract, and that small doses—sometimes as little as 1 gm daily, given continuously—are of distinct value.

With the increasing efficacy of chemotherapy it may be predicted that primary pyelonephritis will ultimately be largely limited to its acute and subacute stages and that chronic infections will develop only occasionally.

## CASE 25221

### PRESENTATION OF CASE

A fifty-four-year-old married Italian shoemaker was admitted complaining of abdominal swelling and edema of the legs.

Four years prior to admission the patient noted a gradual darkening of his skin and at the same time a progressively increasing shortness of breath following mild exertion. One year later he began to suffer from a dull nonradiating pain in his right side just under the costal margin. Eight months before entry his ankles became swollen each evening but were normal in the morning. During the succeeding four months the swelling gradually extended upward to the knees, thighs and genitalia. His abdomen then became enlarged quite rapidly. The pain in the right upper quadrant became more severe. He rapidly lost weight and strength and could no longer work. Dyspnea increased and severe orthopnea developed. At about this time he first noted the presence of small amounts of bright-red blood in his stools and felt a small mass at the anus following defecation. His physician gave him arm injections and did about fifteen abdominal taps at weekly intervals. At each tap "about two bucketfuls" of fluid were removed. He had had neither melena, hemoptysis nor diarrhea. There was no pruritus, and he had noted no change in the color of his eyes. He denied the use of alcohol in any form. Appendectomy and cholecystectomy had been done at some unknown period in the past.

Physical examination showed a cachectic moribund man with marked ascites and edema of the legs. The skin was deeply bronzed and the sclerae appeared to be jaundiced. There was no pigmentation of the buccal mucous membrane. Over the neck and chest there were a few spider-like telangiectases. The neck veins were full and showed visible pulsations. There was marked clubbing of the fingers. Examination of the chest showed subcrepitant rales over both lung bases posteriorly. The lungs were resonant throughout except for slight dullness at the right base posteriorly. Examination of the heart was negative. The blood pressure was 96 systolic, 60 diastolic. The abdomen was distended, and a fluid wave was elicited. The superficial veins were dilated, and

extended up over the chest. Prominent veins were also evident in the axillary regions. A firm, nodular, slightly tender liver edge was palpated 2 cm below the right costal margin, extending from the right midclavicular line to the xiphoid process. No other organs or masses were palpable. The genitalia were edematous. Rectal examination revealed tender hemorrhoids. The reflexes were sluggish but equal.

The temperature was 99.5°F rectally, the pulse 110, and the respirations 30.

Examination of the urine showed a specific gravity of 1.026, a red test with Benedict's solution (following intravenous glucose), 5 to 8 white cells and 10 to 20 red cells per high-power field, no albumin, no bile and no casts. The test for urobilinogen was positive in dilution of 1:40, and doubtful at 1:80, a normal control was positive at 1:20 only. No acetone bodies were present. The blood showed a red-cell count of 3,480,000 with 81 per cent hemoglobin, and a white-cell count of 10,640 with 91 per cent polymorphonuclears. The hematocrit was 36.3. The nonprotein nitrogen of the serum was 21 mg per 100 cc, the protein 5.9 gm and the van den Bergh 1.5 to 2.0 mg of bilirubin, diphasic. The fasting sugar on whole blood was 141 mg per 100 cc. A capillary sugar tolerance test showed a fasting blood sugar of 84 mg per 100 cc, after a half hour 118 mg, after one and a half hours 174 mg, after three hours 240 mg, after four hours 244 mg, and after five hours 194 mg. The fasting blood sodium was 137 milliequivalents per liter. The bleeding time was 2½ minutes, the clotting time 13 minutes, the clotting began in 6 minutes. A blood Hinton test was negative. A bromsulfalein liver function test showed 0 to 5 per cent retention. A Takata-Ara test was strongly positive. A formol-gel test was positive and indicated that the globulin was approximately 5 per cent. Several stool examinations were guaiac negative. An electrocardiogram showed a P-R interval of 0.14 seconds, normal rhythm, flat T<sub>1</sub>, low T<sub>2</sub>, T<sub>3</sub> and T<sub>4</sub>, and low voltage in the QRS complexes. A special stain on a skin biopsy was negative for iron. An abdominal paracentesis yielded 8000 cc of clear, straw-colored fluid with a specific gravity of 1.008.

An x-ray film of the chest showed scarring of both apices and a fine miliary mottling involving the entire lung, being particularly marked in both lower lung fields where there was questionable confluence of some foci. The mottling seemed to have a bronchial distribution. Emphysematous blebs were thought to be present bilaterally but were particularly evident in the left upper lung field. The heart shadow was not remarkable.

On the second hospital day, before intravenous

glucose had been given, the urine showed a yellow test with Benedict's solution. On the fifth hospital day 5000 cc. of clear, light amber fluid was removed from the abdominal cavity by paracentesis, the specific gravity was 1.008. His condition grew progressively worse, and the abdomen rapidly refilled. On the twelfth hospital day 5000 cc. of straw-colored fluid was again removed. The patient refused to take food. His temperature remained essentially normal, the pulse was about 100, and the respirations 20. He gradually failed, and died on the eighteenth hospital day.

### DIFFERENTIAL DIAGNOSIS

DR. JOHN H. TALBOTT. The first time that I read this record the diagnosis was fairly obvious, the second time not quite so obvious, and at the third reading I was thoroughly convinced that the house staff probably puzzled as much over the diagnosis as I have. The patient was fifty-four years of age and an Italian. Dr. Wyman Richardson has called our attention to the fact that cirrhosis of the liver is common in Italians. The patient's first symptom, darkening of the skin, was noted four years prior to admission. Pigmentation of the type described may be observed in four or five different diseases. The first dyscrasia that one thinks about is Addison's disease. Undoubtedly the physicians in charge of this man thought very seriously of a diagnosis of Addison's disease for they requested a serum sodium determination. The concentration was 137 milliequivalents per liter. This is a relatively normal value. I do not believe this patient had Addison's disease in spite of the fact that there was some hypotension and pigmentation of the skin. It is specifically stated that there was no pigmentation of the mucous lining of the mouth. If this patient had had chronic Addison's disease as opposed to acute adrenal insufficiency, he should have had pigmentation in the mouth. At the present time I am not justified in making a diagnosis of chronic Addison's disease without it.

The pain in the right upper quadrant is at least consistent with cirrhosis of the liver. When I use the term cirrhosis of the liver I mean "sclerosis" without etiologic implications, at least not until I summarize the case. There may be sufficient pain from cirrhosis of the liver to warrant surgical consultation, and not infrequently surgical intervention is advised. The anal mass was probably due to hemorrhoids. The small amount of bright-red blood in the stools confirms this impression. The patient was tapped fifteen times before admission and three times afterward. Recurring ascites is not in itself diagnostic as there are several conditions that may require fre-

quent tapping. The injections in the arm were possibly Salvirgan, which is an effective diuretic.

The patient denied the use of alcohol. We do not hesitate, however, to make a diagnosis of alcoholic cirrhosis of the liver in a patient who has a similar negative history. Patients who consume alcohol frequently will not give a correct story.

The skin was deeply bronzed. This is significant. In hemochromatosis or "bronze diabetes," pigmentation of the skin is characteristic. The pigmentation is a blue slate or lead color in contrast to the silver sheen of argyria. In Addison's disease the pigmentation is brown without a metallic tinge.

There were a few spider telangiectases. This is consistent with the diagnosis of intrahepatic disturbance, and nothing more.

The neck veins were full and showed visible pulsation. I should like to attribute these to ascites, and shall not discuss them further.

There was marked clubbing of the fingers. That is an interesting finding. Four or five years ago Dr. Francis M. Rackemann asked me to see a patient with clubbing of the fingers, some respiratory disturbance and unsaturation of the arterial blood. I raised the question of congenital heart disease. Three years later the patient died from cirrhosis of the liver. The oxygen unsaturation which accompanies cirrhosis of the liver is something that has been appreciated in the past three or four years only. Snell<sup>1</sup> at the Mayo Clinic found that 50 or 60 per cent of the cases of cirrhosis of the liver had a saturation of the arterial blood as low as 80 per cent. We occasionally see patients with cirrhosis of the liver who have clubbing of the fingers. I wonder whether the oxygen unsaturation we see frequently associated with cirrhosis of the liver may not be the mechanism of the clubbing of the fingers, which is only infrequently observed in this disturbance. This may be associated with a dysfunction of hemoglobin formation. It is possible that a change in the nature of normally occurring hemoglobin may be the precursor of the pigmentary changes that we see in hemochromatosis, which only rarely follows cirrhosis of the liver. I shall say more about this later.

The question of constrictive pericarditis might be raised, but I think it can be dismissed without further discussion. No spleen was palpable. The patient had ascites at the time they looked for the spleen, and I am wondering if subsequently, after tapping, the spleen was palpable.

The change in the liver is interesting. According to the description the subdiaphragmatic enlargement began in the midclavicular line and went over past the navel process, that is, the

The fasting blood sodium was 137 milliequivalents per liter. The bleeding time was 2½ minutes, the clotting time 13 minutes, the clotting began in 6 minutes. A blood Hinton test was negative. A bromsulfalein liver function test showed 0 to 5 per cent retention. A Takata-Ara test was strongly positive. A formol gel test was positive and indicated that the globulin was approximately 5 per cent. Several stool examinations were guaiac negative. An electrocardiogram showed a P-R interval of 0.14 seconds, normal rhythm, flat T<sub>1</sub>, low T<sub>2</sub>, T<sub>3</sub> and T<sub>4</sub>, and low voltage in the QRS complexes. A special stain on a skin biopsy was negative for iron. An abdominal paracentesis yielded 8000 cc of clear, straw-colored fluid with a specific gravity of 1.008.

An x-ray film of the chest showed scarring of both apices and a fine miliary mottling involving the entire lung, being particularly marked in both lower lung fields where there was questionable confluence of some foci. The mottling seemed to have a bronchial distribution. Emphysematous blebs were thought to be present bilaterally but were particularly evident in the left upper lung field. The heart shadow was not remarkable.

On the second hospital day, before intravenous

tuberculous chronic infection with generalized fibrosis?

DR. HOLMES Yes

DR. TALBOTT In the first place, I do not believe that this man died of a lung condition. I believe that he had a cirrhosis of the liver, and that he died of hepatic insufficiency. I am going to spend a little time discussing the various types of hepatic disturbance that he might have had.

He had an enlargement between the right and left lobe. There is little evidence, so far as the abdominal picture is concerned, that he had malignant disease. I cannot believe he had fifteen or sixteen tapplings of clear fluid from a malignancy alone. There is little evidence that this is an echinococcus cyst. Against liver abscess is the fact that he had no fever at any time. He may have had fever in the past, but he certainly did not in the hospital. If this is syphilitic cirrhosis, I should like to have more evidence of it in the clinical picture, such as a past history of exposure—but I must admit the past history is not reliable—or signs and symptoms of syphilis elsewhere. If we had seen him earlier in the disease we might have given potassium iodide to note whether he responded to therapy in the way that a patient with syphilitic cirrhosis should. On the evidence at hand I do not feel justified in making a diagnosis of hepatic lobatum or syphilitic cirrhosis of the liver. I do not believe that he had diabetes mellitus or that he died in diabetic coma. We have one negative skin biopsy. So far as hemochromatosis is concerned, he had pigmentation and cirrhosis. If he did have hemochromatosis it was of a very mild degree, such as one occasionally sees in patients with cirrhosis of the liver, and had not developed sufficiently to permit a clinical diagnosis or to allow the pathologist to comment on it other than to say that it was a very early form. I might mention acanthosis nigricans, which is associated with pigmentation of the skin. There is little to justify a serious consideration of this diagnosis.

With a negative past history, I do not see how I am able to make a clinical diagnosis of what is going on in the chest. The x-ray films have not helped us except to exclude certain conditions. It is not a very obvious diagnosis and I shall have to leave it undiagnosed. We are then left with the diagnosis of cirrhosis of the liver, which I think was probably alcoholic in origin. I should be more cautious, probably, and call it idiopathic cirrhosis of the liver. I think that he died of hepatic insufficiency.

DR. PAUL D. WHITE This man came to the East Medical Service while I was visiting. I admire Dr. Talbott's discussion of the case. He

has ably expressed our own confusion as we took up one point after another. We tried very hard to make a diagnosis of hemochromatosis but were not successful.

We were very much interested in the relation of the clubbing of the fingers to the pulmonary disease, aside from the possible effect of the cirrhosis of the liver. The statement that Dr. Talbott made about the visible neck-vein pulsation was, I think, very wise. There is no indication, of course, that, with a small and apparently normal heart, cardiac failure would be responsible for such a pulsation. This pulsation was not marked. It can be accounted for, I am sure, by the pressure from a large amount of ascites. Recently, in the past year or so, I have observed a slight jugular pulsation just above the right clavicle even in normal individuals who are very short and whose diaphragms are high. The venous pressure in such cases is normal, even though one can see the jugular pulse.

The electrocardiogram in this case is not particularly helpful. It may mean coronary disease, which need not enter the clinical picture, or a toxic condition and nothing else.

DR. DONALD KING I saw the x-ray films when this patient was on the ward. We raised the question as to whether this might have been a case of dilatation of the bronchioles rather than of the larger bronchi. The honeycomb lesions shown in the films are much like those which have been present in one or two cases of pulmonary fibrosis with bronchiectasis, and in these cases autopsy has shown marked dilatation of the bronchioles.

#### CLINICAL DIAGNOSES

Cirrhosis of liver

Gastric ulcer

Pulmonary fibrosis

#### DR. TALBOTT'S DIAGNOSES

Cirrhosis of liver (? alcoholic)

Undiagnosed lesion in the lungs

#### ANATOMICAL DIAGNOSES

Cirrhosis of the liver, alcoholic type

Pulmonary fibrosis

Emphysema

Bronchiolectasis

Pulmonary edema

Bronchopneumonia

Gastric ulcer, active

Duodenal ulcer, healed

Ascites

Arteriosclerosis

Operative wounds cholecystectomy and appendectomy

enlargement occurred where a middle lobe might be. Many years ago McCrae and Caven<sup>2</sup> called attention to the fact that syphilis of the liver was frequently associated with left-lobe involvement.

The patient had a positive sugar test in the urine on one occasion before any glucose had been given, and again after it had been given internally. The sugar-tolerance curve is not very convincing. We have been studying sugar tolerance in a good many patients with various disturbances, particularly gout, and frequently we find a curve, quite like this, with prolonged elevation. It may remain elevated as high as 200 or 250 mg per 100 cc for three, four or five hours, and we are rather certain that most of these patients do not have diabetes mellitus. Furthermore I do not believe we have anything in the history that justifies our making a diagnosis of diabetes mellitus. The presence of a small amount of sugar in the urine in a patient who has obvious intrahepatic damage can be explained on that basis alone. Lastly, there were no acetone bodies in the urine, and I do not interpret the terminal event as diabetic acidosis and coma.

The blood Hinton test was negative. I mentioned previously that there may be enlargement of the left lobe of the liver in syphilitic cirrhosis, but I hesitate to disregard the negative blood test. I should have been pleased if we had had a Wassermann or Hinton test on the ascitic fluid. That was not done. The bromsulfalein liver test was 0 to 5 per cent retention. This is normal. The Takata-Ara and the formol-gel tests were positive. These are indications of an increase in serum globulin. There has been considerable interest in the past four or five years in the pathologic conditions which are associated with an increased globulin or pseudoglobulin reaction. The three conditions most frequently encountered in which a concentration greater than 40 gm per 100 cc is observed, are multiple myeloma, lymphogranuloma inguinale and cirrhosis of the liver. The first two I am not going to consider. In the third condition the increase may be a combination of two factors. I have just mentioned that a disturbance of formation of hemoglobin and resulting change in the nature of hemoglobin probably occur in cirrhosis. An increase in globulin may be associated with a related intrahepatic dysfunction. A loss of albumin in ascitic fluid with a stress on the protein-forming mechanism is the second factor.

Should we consider malignancy in this patient? The stool examination was negative for blood. There was no hemoptysis, no hematemesis, and the patient passed no large amount of fresh blood by rectum.

The electrocardiogram is of little help to me.

A special stain was done on a skin biopsy. Apparently they were looking for hemochromatosis. However, we do see patients with hemochromatosis in whom the biopsy is negative. Again, this negative test is of no help. I should have preferred either two or three negatives or one positive.

The abdominal paracentesis yielded a fluid with a specific gravity of 1.008, which indicates a transudate and not an exudate.

The interpretation of the x-ray films of the chest is most unsatisfactory to me. Perhaps Dr. Holmes will help with the diagnosis.

DR. GEORGE W. HOLMES: These films show an obvious extensive process involving both lung fields. It is rather generalized, a little more marked at the bases. We have observations on February 6 and on February 13 which show practically no change in the appearance of the chest. Between February 13 and 24, however, there is a very marked change, a difference in the whole character of the picture. It is interesting that his heart is within normal limits both as to size and shape and stays that way, so far as I can determine, throughout the stay in the hospital. He has some tortuosity of the aorta. The whole picture does not seem to be in any way connected with the vascular system. The process itself could be due to a number of diseases. It is not suggestive of tuberculosis but could be due to metastatic malignant disease, to some fungous infection or to one of the unusual forms of peribronchial disease. The terminal picture, I think, is due to edema or pneumonia on top of the previous process. Would you like to have me go farther?

DR. TALBOTT: May I ask a question? Does it look anything like a generalized syphilitic lesion?

DR. HOLMES: I do not know of any generalized syphilitic lesion that would look like that.

DR. TALBOTT: Could leukemia give a picture comparable to this?

DR. HOLMES: It is very unlikely.

DR. TALBOTT: It has been described but we have not been fortunate in seeing it. Possibly we do not consider it so frequently as we should.

DR. HOLMES: That is probably true.

DR. TALBOTT: The only symptoms that were referable to the chest were dyspnea and orthopnea. He had no cough or fever at any time.

DR. HOLMES: It seems strange he did not have cough. I should be inclined to interpret that the way you did the story about alcohol. He must have had some cough. I cannot differentiate the things that I have named.

DR. TALBOTT: Could it be idiopathic or non-

temperature going to 105.6°F. During the night the temperature dropped to normal, where it remained. She was prostrated but had no complaints and no abnormal physical signs. The next day she had oliguria despite a fluid intake of 3000 cc. Sulfanilamide therapy was stopped, the blood level being 14 mg per 100 cc. Her blood pressure was 95 systolic, 60 diastolic. There were several loose stools. She had become nauseated. The non-protein nitrogen of the blood serum was 142 mg per 100 cc. On the following day her blood pressure was 95 systolic, 60 diastolic, becoming 105 systolic, 50 diastolic after two doses of coramine by mouth. She continued passing only small amounts of urine of a low specific gravity. Her temperature was normal. On the tenth hospital day she remained drowsy and vomited small amounts. At this time she was quite jaundiced. Her urinary output had risen to 64 ounces. She refused to take anything by mouth. The area of liver dullness was not diminished, nor was there any tenderness in the abdomen. The chest remained clear and the blood pressure steady at 105 systolic, 50 diastolic. Her sulfanilamide blood level was 9 mg per 100 cc., non-protein nitrogen 137 mg per 100 cc., chlorides 446 (as sodium chloride), icteric index 50 to 60. The red-blood-cell count was 2,600,000, the white-blood-cell count 25,500. The smear was not remarkable. She continued rapidly downhill. On the fourteenth hospital day her stomach seemed to be distended and an unsuccessful attempt was made to pass a nasal tube. She rapidly failed and died on the fourteenth hospital day.

#### DIFFERENTIAL DIAGNOSIS

DR WILMAN RICHARDSON: I feel badly about the statement, "well-marked anemia." I do not know whether she looked anemic or not, or whether anyone did the blood count. This is somewhat important, as you will see later on. However, we will take that as it is written.

We have to explain in this patient fever and chills, evidence of renal failure, jaundice, anemia and death. I want to take them up in that order. In the first place, in regard to her sepsis we have no report anywhere in the record of a blood culture or a throat culture. The clinical description of her disease is typical of beta-hemolytic streptococcal throat infection which has been so prevalent in the past few months. The whole story down to her admission to the hospital is one of a hemolytic streptococcal throat infection. The question is, Do we have to go any farther than that in regard to her sepsis? They have ruled out the possibility of a meningitis fairly well by the lumbar puncture. There is nothing in the story to suggest any localizing lesion except the

renal failure and the jaundice, with the possible exception of the to-and-fro scratching sound over the pulmonic area. This, from the description, was more likely some sort of pleuropericardial rub and of no significance. However, we cannot dismiss entirely the possibility that this patient might have had acute bacterial endocarditis to account for some of the sepsis.

In regard to the question of renal failure, she had oliguria and a rapidly rising non-protein nitrogen with, at the same time, a blood pressure which remained low. Little is said about the organized sediment in the urine, which might have been of help. In bacterial endocarditis we frequently have a nephritis which is usually embolic in, I think, 90 per cent of cases, but it may be a true glomerulonephritis in the remaining ten per cent. However, in this case it is very difficult for me to see how the patient would reach this rapid termination in so short a time. Most of them will go on longer. Certainly if it were a focal nephritis from streptococcal infection, again the course would not be so fulminating. I would not expect even acute glomerulonephritis to go to this point so quickly. Nothing is said about hemorrhage from the kidney. It is mainly a matter of anuria for a good many days. I note, however, that her urinary output did increase shortly before death.

Let us leave the discussion of renal failure for a moment and go on to the symptom of jaundice. She had a large amount of sulfanilamide which was trapped in the blood stream when the kidneys shut down and remained there for six or seven days. She is entitled to have a hemolytic type of anemia from sulfanilamide. In such a case one would expect to find in the blood smear more evidence of red-cell regeneration, although it is possible that sepsis may inhibit the bone-marrow response. The cases of hemolytic anemia from sulfanilamide that I have seen have shown obvious evidence of red-cell regeneration on examination of the smear. However, if she did have hemolytic anemia from sulfanilamide she is entitled to a small amount of icterus but not an icteric index of 50 or 60, if we can take that as accurate.

Another thing we have to consider is toxic hepatitis on the basis of either infection or sulfanilamide. I do not know of any case of real toxic hepatitis as a result of sulfanilamide, but I am sure that we are going to see them and it may be that this is one. I note that, when patients get too large doses of sulfanilamide for a long time, their breath begins to have a sweetish, musty odor. This to me indicates liver failure and it is always a warning to stop sulfanilamide at once.

The question whether this anemia might be due to the sepsis alone is impossible to determine.

## PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY The autopsy on this man showed as the primary disease a very extensive cirrhosis of the liver. It was atrophic, with nodules of regeneration of considerable size. It was not very clear to us at autopsy why one portion had been so readily palpable. There was no point of particular prominence.

The liver microscopically showed minimal traces of iron but certainly not enough to justify a diagnosis of hemochromatosis. A slight increase in intrahepatic iron is a common thing in cirrhosis of the liver. Chemically it can usually be made out, and histologically it is often seen in cases which are not primary hemochromatosis. In a few places we could find quite typical hyalin of the alcoholic type, although that is an unusual finding in an Italian. The spleen weighed only 150 gm so it could not have been felt. There were no varices. The pulmonary lesion I cannot name any better than the clinician could. There was an extensive pulmonary fibrosis with some dilatation of the bronchioles and a great deal of intimal thickening in many of the pulmonary arteries. At this late stage of the game it would be difficult to say whether the arterial change was primary or secondary. My guess is that it was secondary, and I should assume that at some time in the past this man had had an extensive focal pneumonitis followed by organization rather than resolution and that all the changes were secondary to that. We could find nowhere anything that suggested pulmonary tuberculosis. What the etiology was, I have no idea.

The upper abdominal pain may of course have been due to the cirrhosis of the liver, as Dr Talbott suggested. However, he had an active gastric ulcer and the scar of a healed duodenal ulcer as other possible factors.

DR WHITE Was the right ventricle enlarged?

DR MALLORY No. The heart weighed only 250 gm.

DR TALBOTT Was there anything in the kidneys to explain the hematuria?

DR MALLORY Nothing of significance — only slight vascular changes.

DR HOLMES What was in the lungs to explain the marked change during the period of observation?

DR MALLORY Terminal edema and bronchopneumonia.

## CASE 25222

## PRESENTATION OF CASE

A forty-two-year-old housewife was first seen six days before admission to an outside hospital complaining of chills, fever and sore throat of three days' duration.

She had had two chills in the evening lasting from five to ten minutes and her temperature on one occasion was 101°F. She had vomited once. Examination showed a large, swollen, tender area in the left submaxillary region. The left tonsil was swollen and very red. She could not open her mouth more than half way. The temperature was 103.2°F. During the first thirty-six hours she was given 240 grains of sulfanilamide and 60 grains more during the next twelve hours. On the second day after this therapy was begun her temperature was 101°F and the swelling in the throat had slightly decreased. On the third day her white-blood-cell count was 3400 and the sulfanilamide therapy was promptly stopped. The next day she was prostrated, confused and very cyanotic. The neck was still very tender, but the swelling in the throat had greatly receded. The temperature was 98°F, the white-blood-cell count 30,000. On the following day there was much less prostration and she was no longer confused. The white-blood-cell count was 17,800, temperature 98.6°F. The neck and throat were practically normal. On the sixth day she had a chill lasting a half hour. Soon afterward her temperature was 105°F, pulse 140, respirations 24. She was then admitted to the outside hospital.

Physical examination showed a well-developed and nourished woman whose throat was slightly red, but otherwise normal. Examination of the eyes was negative. There was no glandular enlargement. The chest examination was negative except for a to-and-fro scratching sound over the pulmonic valve area which was thought to be due to her very rapid and forceful heart action. The abdomen was slightly distended but otherwise negative. Neurological examination was negative.

She was given 100 grains of sulfanilamide with out obvious effect. A lumbar puncture showed normal dynamics and a clear colorless fluid. Her nonprotein nitrogen was normal. Large doses of sulfanilamide were decided on. On the second hospital day the blood sulfanilamide level was 117 mg per 100 cc. The blood showed a white-cell count of 34,000. She had a well marked anemia. During the night she had another chill lasting a half hour followed by a temperature of 104°F. A transfusion was given in the afternoon. On the fourth hospital day she had a second transfusion during which she had a severe chill, the

perimental results seem clear cut and seem to check very closely with the formation of the hemoglobin casts, so that at the present time it seems reasonable to me to accept the theory

In addition to the kidney findings there was a septic tonsillitis. There had evidently been some degree of thrombophlebitis in the peritonsillar veins because the lungs showed multiple septic emboli and the beginning of abscesses. There was no endocarditis and there was neither pleuritis nor pericarditis to explain the rub.

DR. CHAMP LYONS: The course of this disease strikes me as being more like that caused by the staphylococcus than the streptococcus. Were there any cultures?

DR. HUGH A. STOUT: The postmortem blood culture was sterile.

DR. MALLORY: The liver showed jaundice. It was swollen and there were a few more leukocytes in the sinusoids than normal, certainly no extensive destruction of liver cells. I think one can say that there is a minimal hepatitis, whether it was due to the transfusion reaction, to the sepsis or to sulfanilamide, I certainly cannot say. There was no extensive hepatitis, however.

DR. RICHARDSON: One is at a loss to explain the jaundice. If this were *Staphylococcus aureus* septicemia there might be a hemolytic anemia, increasing the jaundice that you get from sulfanilamide.

DR. BERNARD M. JACOBSON: I should like to ask if sulfanilamide renders typing of the blood at all difficult.

DR. F. T. HUNTER: It should not interfere if the typing is properly carried out.

DR. BREED: I should like to ask why it seems more like a staphylococcal than a streptococcal process.

DR. LYONS: There are several things that made me think of that. First, she had an abrupt onset of chills with a fever that did not respond to sulfanilamide therapy. The white count went to 3400 on administration of sulfanilamide, but it did not similarly drop on the second administration of comparable doses. I think leukopenia is more apt to be associated with staphylococcal infection because of the leukocidin toxemia. The late recurrence of chills again is suggestive of a septic thrombophlebitis and the late thrombophlebitis with the manifestation of chills is much more apt to go with staphylococcal than streptococcal infection because of the nature of the inflammatory response that is elicited by staphylococcus. I think that the jaundice and theiliary lung abscesses which progressed after the acute infection subsided are more suggestive of staphylococcus than streptococcus when one considers the amount of sulfanilamide that was given.

A PHYSICIAN: Is sulfanilamide as apt to render the blood culture negative in staphylococcal infections as in streptococcal ones?

DR. MALLORY: I should think not.

DR. EDWARD A. GALL: What is the opinion regarding the height of jaundice following incompatible transfusion?

DR. HUNTER: That is hard to know because she had hemoglobin with much brownish color so that the icteric index is often read three times as high as it should be. A van den Bergh reading would be better.

It might be due either to sulfanilamide alone or to sepsis or most probably to both. In regard to one laboratory finding, the low chloride, the exact explanation is not clear, although it may have been the result of the previous high fever and sweating with considerable vomiting. I should think that was the most reasonable explanation.

She died, and why did she die? I think as you look over this story you find that things were progressing quite well when she had an episode of leukopenia which scared her physician. He stopped the sulfanilamide and the patient responded rapidly. She was still septic, however, as many of the patients with streptococcal disease have been this year. Then something happened. On the fourth hospital day she was given a transfusion during which she had a severe chill. She has had so many chills that we may have become more or less desensitized to them. She has a transfusion, a sudden chill, and oliguria. I believe this patient was given incompatible blood, and that she had agglutinins in the blood serum of low titer, so that immediate reaction was not apparent, but that she did have transfusion renal failure. If that is the case it might cause hemolysis of the donor's cells and increase the icterus to a slight extent but not to 50 or 60. I still do not think we have explained her severe jaundice. I think the severe jaundice is due to what Dr. Mallory will call a toxic hepatitis, which I believe is due to sulfanilamide, but it may not be possible to tell whether it is that or toxic hepatitis from infection. I should like to say one thing more. I may be wrong about the transfusion reaction. It is said to be due to plugging in the kidney tubules, due to precipitation of hemoglobin. That may be true and is a perfectly good theory. I would ask why the patients with paroxysmal hemoglobinuria have hemolysis of the blood, often massive, and still do not go into immediate renal failure. I do not see any difference, although there may be some explanation I do not know about. It is of course conceivable that there is some infectious process in the abdomen, an appendix with appendiceal abscess or phlebitis and multiple liver abscesses, jaundice and death. I mention them but I see no evidence for them, and I will not consider them further. I will say, then, that the patient had infection with beta-hemolytic streptococcus, arising in the throat, that she had an incompatible transfusion, with renal failure, and that she had a toxic hepatitis on the basis of prolonged administration of sulfanilamide.

DR. TRACY B. MALLORY: Are there any suggestions?

DR. WILLIAM B. BREED: Would you on examination be able to determine that a patient had died as a result of incompatible transfusion?

DR. MALLORY: I believe so.

DR. BREED: On what basis?

DR. MALLORY: I shall proceed to tell you because I think that was the case here.

#### CLINICAL DIAGNOSES

Acute yellow atrophy of liver  
Sulfanilamide poisoning?

#### DR. RICHARDSON'S DIAGNOSES

Beta-hemolytic-streptococcal infection (arising in throat)  
Incompatible transfusion, with renal failure.  
Toxic hepatitis

#### ANATOMICAL DIAGNOSES

Sepsis, type undetermined  
Septic infarction of the lung with abscess formation  
Hemoglobin nephrosis  
Toxic hepatitis, slight

#### PATHOLOGICAL DISCUSSION

DR. MALLORY: As you have noted from the record this patient was never in the Massachusetts General Hospital, although she was seen by various members of our staff in consultation. At autopsy the kidneys were a little enlarged. They weighed 400 gm. whereas 300 gm. would have been a fair size for a woman of her build. The gross characteristics were not very striking. There were some reddish spots that looked hemorrhagic, but the cortex was only slightly swollen. On microscopic examination the outstanding feature was the plugging of most of the collecting tubules with orange masses of precipitated hemoglobin. It is, I think, difficult when looking at sections from a case of this sort to convince oneself that every tubule is plugged and that the renal insufficiency can be explained purely by intrarenal hydronephrosis as has been claimed.

There is a certain amount of experimental work\* which is interesting in this regard. It has proved possible in dogs to produce renal shutdown by hemolytic agents or the infusion of hemoglobin in solution, and it has been found that the development or the failure of development of renal insufficiency apparently depends on the reaction of the urine. If the urine is acid at the time that the hemoglobin passes through the glomerulus it is apparently precipitated in large amounts in the tubules. If the animal has previously been given alkalis in sufficient quantity to keep the urine alkaline no renal deficiency develops. The ex-

\*DeGowin E. L., Warner E. D. and Randall W. L. Renal insufficiency from blood transfusion. II. Anatomic changes in man compared with those in dogs with experimental hemoglobinuria. Arch. Int. Med. 61:609-630, 1938.

Channel for a protracted tour to Paris, Lyons, Montpellier and finally the Riviera, making his headquarters at Nice from November, 1763, to May, 1765. He shrewdly saw the great future of Nice and Cannes and envisaged the Cornice road, later designed by Napoleon. Although of choleric temperament and somewhat jaundiced in most of his views of what he saw abroad, he nevertheless had his letters published on returning to London in 1766. These *Travels through France and Italy* (London, 1766) give an accurate account of what he observed and served to stimulate interest in the Riviera as a pleasure and health resort.

There is little of medical interest in the two volumes, although some of the letters are to a doctor. In Montpellier he consulted a celebrated French professor of medicine by a letter written in Latin. The reply, in French, indicates that the learned gentleman could not read Latin or did not bother to read Smollett's notes. When sent back, with passages marked, the answer was equally irrelevant. Guessing the cause of Smollett's illness to be tuberculosis, he advised turtle-soup! Smollett was not well. His asthma and rheumatism prevented him from looking up some manuscripts for his friend, John Hunter. In Nice he kept a detailed register of the weather from November, 1763, to March, 1765, which is appended to his *Travels*.

Smollett's whole life, however, is of more than usual interest to physicians. After an apprenticeship of five years with a doctor, Smollett became a fleet surgeon and later lived in Jamaica, where he married his Creole wife, who was so devoted to him in his latter years. Returning to London, he was closely associated with Hunter, Pitcairne and Smellie, while practicing surgery. He was soon drawn to coffee-house society, became noted as a raconteur and, in spite of a move from Westminster to Mayfair to gain practice, the world of letters was more to his liking. *Roderick Random* came early, published when he was only twenty-seven, *Peregrine Pickle* and *Count Fathom*, a few years later. *Humphrey Clinker*, his masterpiece, was written in 1770, in Italy. His life was drawing to a close and he wrote John Hunter in 1771

"If I can prevail upon my wife to execute my last will, you shall receive my poor carcass in a box after I am dead to be placed among your rarities. I am already so dry and emaciated that I may pass for an Egyptian mummy without any other preparation than some pitch and painted linen."<sup>2</sup> Dying in Italy, however, he was buried two days later in Leghorn, his wife, apparently, thought that best.

## MASSACHUSETTS MEDICAL SOCIETY

## ANNUAL MEETING NEWS

## MOVING PICTURES

The value of moving pictures in the demonstration of medical topics is well recognized. This year the Committee of Arrangements has procured a large number of films illustrating a variety of conditions, and has arranged to present these as a continuous program from 10 a. m. to 5 p. m. on Tuesday and Wednesday, June 6 and 7. These pictures will be shown in the Musicians' Room, which is on the main floor of the Municipal Auditorium. The program will be run on a published schedule and consists chiefly of fifteen-minute films. This arrangement will make it possible for members to select the topics of individual interest at convenient hours. Mr. Warren Sturgis, who is specializing in the production of medical moving pictures, will be in direct charge of the program. On Thursday morning, an opportunity will be given for repeating those films in which the greatest interest has been shown during the two preceding days.

## GOLF TOURNAMENT

The Golf Tournament, which has become so much a part of the June meetings of the Society will be held at the beautiful Wachusett Golf Club in West Boylston, a four-mile drive from the Auditorium. An innovation will be made this year in that play will be possible on two afternoons instead of one as has formerly been the case. This change has been made so that golfers can arrange their program and not miss meetings in which they are particularly interested. The starting play on the afternoons of Tuesday and Wednesday, June 6 and 7, will be from 1.30 to 3.00 o'clock, and the greens fees will be \$1.00 on Tuesday and \$1.50 on Wednesday.

The principal prize this year, as last, will be

COMMUNICATIONS should be addressed to the NEW ENGLAND JOURNAL OF MEDICINE, 8 Fenway, Boston, Mass.

## THE SCIENTIFIC AND COMMERCIAL EXHIBITS AT THE ANNUAL MEETING

THE forthcoming meeting of the Massachusetts Medical Society is featuring twenty-one scientific exhibits. The Massachusetts Department of Public Health will demonstrate not only several different types of work directed from the State House but also that carried on at the Rutland State Sanatorium and the Pondville Hospital. Certain important activities of the American Medical Association, such as the dissemination of information concerning syphilis, the work of the Council on Foods, the Council on Physical Therapy and the Council on Pharmacy and Chemistry, will be shown in a series of booths.

In line with the policy of the Committee of Arrangements to stimulate interest among the local hospitals to exhibit certain of their activities and

interests, there will be four exhibits by members of the staffs of the Worcester hospitals. These include demonstrations of pathologic lesions in the genitourinary tract and of the treatment of certain types of fractures. An unusual exhibit on the production of milk with a high mineral content is to be put on by the medical milk commissions of Boston, Worcester and Springfield. This is the first time that a demonstration of this type has been shown in the Scientific Exhibits, and all physicians should become acquainted with the modern methods of improving the quality of one of our basic foods.

So much is offered in these scientific exhibits that is of interest and value to practicing physicians that none should fail to avail themselves of the opportunity to learn about some of the recent advances in medicine.

The number of commercial exhibits at this year's annual meeting is greater than ever before. Many old friends are back, and in addition, a number of well-known medical-supply houses are exhibiting for the first time. It is hoped that, old or new, they will be received with a keen show of interest. It should be realized that it is the amount of interest shown by physicians as evidenced by their visits to the various booths, that in the end determines the amount of exhibition space sold at these meetings, and hence their cost to the Society.

Many of these exhibits are extremely interesting and have been designed to show in an attractive form the new products as well as time tested ones. Much can be learned, if the physician is willing to spend a little time in examining them. Everyone is urged to register at all the commercial exhibits, and thus help to ensure prosperous meetings in the future.

## THE LITERARY PHYSICIAN

Few physicians have led a more harassed life than Tobias Smollett. Overwhelmed with his editorial duties with "his minions about him, to whom he prescribed tasks of translation, compilation or abridgement,"<sup>1</sup> three months in jail and the death of his daughter, Betty, in 1763, brought him to the breaking point. In June, 1763, he crossed the

## LEGISLATIVE NOTES

At a meeting of the Committee on State and National Legislation, on Wednesday, May 24, the Chairman was authorized to go before the Senate subcommittee considering the Wagner Bill. The final wording of his statement was arrived at only after consultation with Senators Lodge and Walsh and after a detailed discussion of it with Drs Edward H Cary, Walter F Donaldson, Roscoe L. Sensenick, Olin West, Morris Fishbein, William C Woodward, and William D Cutter of the American Medical Association who helped to bring it into its final form and unanimously approved it. Dr Cary, who presided over the Association opposition to the bill, introduced the writer to the subcommittee.

STATEMENT OF DR. CHARLES C LUND, OF BOSTON, MASSACHUSETTS, CHAIRMAN, COMMITTEE ON STATE AND NATIONAL LEGISLATION OF THE MASSACHUSETTS MEDICAL SOCIETY, TO THE SUBCOMMITTEE OF THE COMMITTEE ON EDUCATION AND LABOR OF THE UNITED STATES SENATE, CONSIDERING THE WAGNER BILL, SENATE 1620 MAY 26, 1939

The Council of the Massachusetts Medical Society, which is our legislative body, has not met to consider the Wagner Health Bill, Senate 1620. However, the Committee on State and National Legislation has given the bill very serious consideration and has authorized my appearance to discuss it.

At the present time the United States Government in one way or another is carrying on or aiding medical activities through a great multitude of bureaus and departments. These activities operate under a great mass of diverse laws and regulations and are not always well co-ordinated. President Roosevelt has, with the consent of Congress, just taken a step of fundamental importance that has met with widespread approbation even in New England. That step is the regrouping of several agencies of the government. Is it too much to expect that the majority of the present federal medical activities (except the Army and Navy services), and all future ones, if new ones are created, shall be placed together? We realize that there were probably sound reasons to explain how the present complex situation arose. But is such a situation still sound? The greatest defect in the bill is that it not only perpetuates overlapping of medical activities in separate departments but even adds to overlapping by giving the Social Security Board new and widespread medical functions.

How cumbersome this proposed situation is may be seen by the authorization in the bill of 245 and more state and federal advisory councils (not counting those for the District of Columbia, and so forth). Now the advisory council idea is, per se, excellent. But there should be one federal council and one council for each state and territory, —not five for each. Also, these councils should be created at once and given the broadest possible advisory powers, so that they would have under their consideration any medical problems arising in connection with any governmental activity. The councils should be so constituted that the medical profession and the public are both adequately represented. Our state health department is well run by such a council.

The provision in the bill that gives the Federal Government the power to refuse grants to states that do not have a merit system of appointment and promotion in the departments spending the grants is, in our mind, very good and one of the most important provisions of the bill. Of course, we don't want any more interference in our local

affairs than is necessary. But we feel that we have a right to be assured that any federal funds spent on the care of the needy will not pass through the hands of inefficient political appointees.

In this connection, we have another suggestion. One item in the cost of illness is the cost of medical care of totally needless illness. We in Massachusetts naturally object to paying for the care of such patients either in our own or any other state. It would not require any federal funds for every state to abolish smallpox. The methods of doing this have been available for years. The cost is low and well within the possibilities of budgeting by the poorest states. Nevertheless, why was the average incidence of smallpox in this country 7600 cases per year from 1933 to 1937, inclusive? Purely because the responsible officials and the public have either failed to see that the proper control laws have been passed by their legislatures or they have not enforced their laws. We suspect that either the educational, political, or public health organization in these states is of such a nature that subsidized medical care might not be appreciated or efficiently utilized.

Now we want to discuss a purely financial question that we know is uppermost in the minds of many doctors who criticize this bill vociferously. That is, where is the money coming from to pay the bills? Only a few doctors start to practice medicine with any capital except what they have invested in their education. They expect to save money and invest it for their old age, if they can. The immediate effect of this bill would probably be to increase the incomes of some doctors. That, of course would be of immediate benefit for them. But doctors are trained to look beyond immediate results in all their work. Here they look at a government that has been going into the red for many years. They realize that much of the increase in debt was not to be avoided. In so far as the enactment of this bill may increase the expense of government, it will further the tendency to inflation that many people think is steadily in progress. The doctors wonder, and in this they are like millions of other Americans, what their savings will be worth some years from now. The doctors

the honor of having one's name inscribed on the Burrage Bowl, presented last year by Dr Walter S Burrage in memory of his father the late Dr Walter L Burrage, who was secretary of the Society for so many years. Custody of the bowl, which is awarded for the low net score, was won last year by Dr Roy E Mabrey. The local committee in charge of the tournament is offering prizes for the three low net scores and the three low gross scores and three for the winners in the kicker's tournament. Club or state handicaps will be necessary in playing for the net or gross prizes.

The prize winners this year will have the distinction of receiving their prizes at the annual dinner where the presentations will be made by the president, Dr Channing Frothingham. A luncheon will be served to any members who wish to eat at the club before starting play. Reservations can be made by telephoning the club at West Boylston 110.

At the registration desk in the Auditorium there will be handbills giving directions to reach the club and any other necessary information.

Boston

### BLEEDING IN THE PUERPERIUM

Mrs M G M, a thirty-year-old gravida II, was discharged from the hospital on the eighteenth day following a normal delivery and convalescence. On January 13, 1936, two days after she arrived home, she reported by telephone that she was flowing very freely.

The family history was non-contributory. The patient had had scarlet fever and measles in her childhood. She had had a routine tonsillectomy but no other operations. Catamenia began at fourteen, were regular with a twenty-eight-day cycle and lasted seven days, with no discomfort. Her last period was March 13, 1935, making the estimated date of delivery December 18. Her first pregnancy had been terminated by a simple forceps delivery after a labor of not over six hours.

As she lived 20 miles in the country, a physician in a nearby town was asked to see her following the telephone call. Three quarters of an hour later the bleeding recurred, and it was advised that she be brought into the hospital. There was a great delay in getting an ambulance, and the patient did not arrive at the hospital until three hours after she had first been seen. On entry she was pulseless, no blood pressure could be obtained,

and she was still flowing, but not excessively. One quarter grain of morphine was given immediately, and under nitrous oxide and oxygen anesthesia a vaginal examination was performed. A large piece of retained placenta was found in the cervical canal. This was removed by the fingers, and an iodine strip was left in the uterus. Intravenous glucose solution was given at the start of the operation. Half an hour later the blood pressure was 60 systolic, 40 diastolic, and after another half hour 90 systolic, 60 diastolic. The pulse at the latter time was definitely palpable, with a rate of 110. It was believed that, although the need of transfusion was not urgent, convalescence would be improved if it were done. In consequence, a citrate transfusion of 750 cc was given, the husband of the patient being used as the donor. The pack was removed from the uterus the day following operation, and there was no subsequent bleeding. For several days her temperature ranged from 100 to 101°F in the afternoon. She was discharged from the hospital two weeks after entrance.

The following is a report of her blood examinations: January 14, hemoglobin 50 per cent, red-blood-cell count 2,270,000; January 18, hemoglobin 60 per cent, red-blood-cell count 2,820,000; January 21, hemoglobin 70 per cent, red-blood-cell count 3,070,000; January 27, the day of discharge, hemoglobin 75 per cent, red blood-cell count 3,820,000.

*Comment.* The retention of a piece of placenta is the commonest cause of serious bleeding in the puerperium. In this particular case the placenta was looked at carefully when the baby was born, and although it was a little irregular, it was not evident that a piece remained in the uterus. Even if it had been thought that a piece of it had been left, conservatism would have been the ideal treatment in the absence of any undue bleeding during the entire stay in the hospital.

This hemorrhage came on very suddenly and without warning, and the patient must have flowed tremendously. It was unfortunate that the delay occurred in getting her into the hospital. When she arrived, she was in very poor condition. Transfusion was not done immediately because there was still some bleeding and it seemed very important that this be stopped.

It cannot be advised too strongly that all cases of bleeding should be checked by blood examination, only in this way can the total amount of blood loss be accurately determined—observation gives only an estimate at best. Furthermore, the therapeutic value of transfusion cannot be over-emphasized.

\*A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

and by radio, the medical aspects of cancer have been frequently presented. Positive results of this campaign have been noted in the steadily increasing number of individuals who have visited the tumor clinics for advice and treatment. No new tumor clinics have been added during the past year. The list is as follows:

Central Maine General Hospital, Lewiston, Eastern Maine General Hospital, Bangor, Maine General Hospital, Portland, Sisters Hospital, Waterville, St. Mary's General Hospital, Lewiston, Thayer Hospital, Waterville.

Members of the Cancer Committee have served as clinic personnel, along with other members of the institutional staffs.

Figures from the office of the Women's Field Army show that the Joseph W. Scannell Memorial Fund was exhausted October, 1938, so great was the increase in demand for services to the indigent. Benefits from this fund were widely distributed throughout the State.

The question has been brought up of placing other diagnostic clinics at strategic points in the State in areas not now easily covered. These would serve to lighten the load on some of the large centers. A study of this problem is now going on, and key men are being contacted with the idea of inaugurating such diagnostic centers. Because of the requirements of high voltage roentgen therapy and radium, only the large clinics are likely to carry on the therapeutic measures of radiation.

Early in the year a symposium on cancer was prepared by a committee member, Dr. Edward H. Risley, of Waterville, acting also in his capacity as chairman of the Advisory Board of the Women's Field Army. Contributions to this symposium were made by members of the Cancer Committee and other medical members of the Advisory Board. Under appointment, requested by the Committee on Graduate Education, Dr. Risley plans to offer this symposium for panel presentation at a meeting of the county medical societies.

In review it may be stated that cancer work in the State is much more active than it has been for years. The educational activities of the Women's Field Army for the Control of Cancer, backed by the personal and professional co-operation of the members of the Maine Medical Association, are helping the laity, as a whole, to become more and more cancer-conscious. The biggest problem now seems to be to synchronize the educational work with funds available for carrying the increasing load of indigent patients who seek treatment for cancer.

FORREST AXES, *Chairman*

#### REPORT OF COMMITTEE ON GRADUATE EDUCATION

One of the most important responsibilities facing state medical associations is that of providing an adequate program of graduate education. The problem varies in different states, due to many local factors. Consequently there are bound to be many variations among the several programs which are being developed. A permanent organization of the different state committees on graduate education has been effected, for mutual benefit and exchange of ideas. Your chairman has attended each meeting of this central organization and plans to be present at the next meeting in St. Louis at the time of the meeting of the American Medical Association.

Your committee has had several meetings during the year and has been in conference with the Council and the county secretaries.

Because of the unique advantage accruing to the State through the Bingham and the Commonwealth fellowships, our program naturally becomes divided into two parts: the first is intramural and is concerned with making available adequate educational programs within the State,

and the other has to do with the wider utilization of courses available in Boston.

It was decided to develop our intramural program in conjunction with the county societies. After some experimentation, in an endeavor to find the most interesting type of program, a series of panel discussions were prepared and offered to the county societies. Panels on the following subjects are now available: Pneumonia, Cardiovascular Disease, Fractures, Acute Appendicitis and Complications, Laboratory Methods and Their Application in Clinical Medicine, Surgery of the Thorax and Cancer. It is expected that panels concerning other subjects will be developed from time to time, depending on the demand. So far this type of program has seemed very popular and worthwhile.

Your committee has co-operated with the directors of both the Bingham and the Commonwealth funds in an endeavor to have the available fellowships allocated where they are most needed. For the most part these fellowships have been intended for men practicing in the small communities. As nearly as can be estimated about 15 per cent of our members have taken advantage of these fellowships. Perhaps another 10 per cent have been providing their own educational programs through long-established hospital or society affiliations—and need not enter the picture. Of the remaining 75 per cent, eliminating the men near retirement age, there must be about 50 per cent who should have facilities for some form of graduate study. An intramural program is essential in order to reach them. In turn, this may stimulate interest in some phase of our extramural program. At present it does not seem necessary to expand our program but rather to co-ordinate and develop what we already have. The sole exception to this might be where, in certain counties, such as Aroostook, the geographical problem makes it difficult to attend meetings, especially during the winter. Here it might be well to consider the question of intensive intramural courses—to be given during the summer. If there be sufficient local interest, such a program can be developed and financed without expense to the local groups. It is understood that the Bingham Associates are developing another form of fellowship, giving short intensive courses of one week's duration. These will provide study on more specialized subjects than heretofore available and should appeal to a greater number of our members.

The following recommendations are made:

(1) Greater co-ordination between the programs of the annual meeting and the Fall clinical session and the program of graduate education. While there is no desire to interfere with the committees in charge of these two annual events, the Committee on Graduate Education necessarily must have a long range viewpoint, and co-operation between these committees might result advantageously for all concerned.

(2) Continuation of the panel-discussion type of program—through the county societies.

(3) Further development of the hospital staff program, utilizing the available material for case study.

(4) Participation of the association as an organization in the New England Postgraduate Assembly. This has already proved its usefulness. It offers a great deal in the way of postgraduate education.

(5) Co-operation with the Bingham and the Commonwealth funds in the extramural programs—through greater utilization of the available fellowships. Through application to the committee, courses on any desired subjects may be obtained for groups of four men.

F. T. HILL, *Chairman*

would look with more favor on a bill that went much more slowly and which did not contain in any place the rather frightening phrase 'such sums as may be needed to carry out the purposes of this title, coming as it does repeatedly, after the mention of sums, which, while they may not be very large in the national economy, seem enormous to the individual citizen

There are wide discrepancies among various estimates that have been made as to the number of people who for financial reasons now do not obtain medical care. Everyone admits that the group that most needs to be provided with medical care is that group which has no appreciable income on which to exist. We suggest that before starting to furnish federal aid for the medical care of employed people, medical care to be furnished under the bill be limited to the indigent and the medically needy. If the lowest estimate of the numbers of medically needy and indigent persons is correct it will be a very small matter to rectify—but, if the highest estimate is correct, the problem is so enormous that it will take all the possible available resources in money and trained men, without at the same time taking on the other even greater problem of aiding in the care of those who are better off

I make a plea for co-operation between the doctors and the government. In Massachusetts a most remarkable thing has happened. The adjusted death rate for cancer in women has been decreasing for five years and the rate for men has become level. This is the only state in the Union where this has occurred, and it has not occurred in any foreign country. This has been accomplished by the simultaneous use of two means. First, the establishment of state-aided cancer clinics about twelve years ago helped a little. But during the first few years of operation of the clinics there was no decrease in the elapsed time from the onset of the cancer to first treatment of it which is the most important factor in controlling an individual case.

Secondly, for five years, the State Department of Health has been promoting the education of the public in an original manner. Women's clubs are stimulated to ask for lecturers on cancer. They are encouraged not to go outside their town in search of an expert, but to invite one of their general practitioners. If the doctor believes that he is not prepared to give such a talk, he is provided with suitable material prepared for him by the Massachusetts Medical Society and the State Department of Public Health. This serves two purposes. (1) it educates the public, and (2) it educates the doctor. The cases are now coming in months earlier and the results improving steadily.

#### SUMMARY

If federal legislation concerned with the public health is to be enacted, it should be directed toward the following objectives:

- 1 Unification of most of the present medical services of the federal government, except the Army and Navy services. All future federal medical activities should be added to this group.

- 2 Representative medical advisory councils to work with the federal and state medical officers.

- 3 Expansion of activities where clear evidence of need for expansion is proved.

- 4 Support of existing recognized hospitals, rather than building new governmental ones for the care of the indigent, thus reducing the number of vacant hospital beds instead of increasing it.

#### DEATHS

**HOLTON**—CHARLES E. HOLTON, M.D., of 391 High Street, Medford, died May 22. He was in his seventy-second year. Born in Lee he received his degree from the University of Vermont College of Medicine in 1892. For more than thirty years he was an investigator in the food and drug control division of the United States Department of Agriculture.

Dr. Holton was a former member of the Massachusetts Medical Society.

His widow and a daughter survive him.

**MAYO**—CHARLES H. MAYO, M.D., of Rochester, Minnesota, died May 26. He was in his seventy-fourth year.

Born in Rochester, Minnesota, he received his degree from Northwestern University Medical School in 1888. With the death of his father, he and his brother inherited a general practice and their father's interest in St. Mary's Hospital. The Mayo Clinic was formally organized in 1912, and in 1915 the Mayo brothers gave \$1,500,000 to establish the Mayo Foundation for Medical Education and Research in affiliation with the University of Minnesota. Dr. Mayo was a past president of the American Medical Association and the American College of Surgeons.

Among his affiliations were fellowships in the American Medical Association, American Surgical Association, Southern Surgical Association, Western Surgical Association, American College of Surgeons and the Society of Clinical Surgery. He was professor-emeritus of surgery at the University of Minnesota Medical School.

His widow, a son, Dr. Charles W. Mayo, four daughters, and a brother, Dr. William J. Mayo, survive him.

**SHINN**—PHILIP A. SHINN, M.D., of Rockland, died May 23. He was in his fifty-fifth year.

Born in Portland, Maine, he received his degree from Tufts College Medical School in 1915, and interned for two years at the Robert Breck Brigham Hospital, Boston. Dr. Shinn was a lieutenant in the naval medical corps during the World War and served more than a decade at the veterans hospitals in Northampton, and Augusta, Maine. Eight years ago he joined the staff of the Boston Dispensary.

He was a member of the Massachusetts Medical Society, the American Medical Association, the American Psychiatric Association and the New England Society of Psychiatry.

A son and a daughter survive him.

#### MISCELLANY

##### MAINE NEWS

##### REPORT OF THE CANCER COMMITTEE

A review of the activities of the Cancer Committee reveals evidence of individual and collective co-operation rather than separate endeavor of the committee as a functioning unit. In other words, the work of the members of the committee has been so closely tied up with the public activities of the Women's Field Army for the Control of Cancer that there has been little room for other projects by the former. However, it would seem that this particular method of presenting constructive cancer work has not been without evidence of progress.

The educational campaign of the Women's Field Army has been eminently successful. To this campaign, various members of the Cancer Committee have contributed much in personal time and effort. Speaking before lay groups

tor will get in touch with the nearest policeman in any such cases, the officer will be only too pleased to assist the members of the Massachusetts Medical Society in every way possible.

CHANNING FROTHINGHAM, M.D.,  
President, Massachusetts Medical Society

## REPORTS OF MEETINGS

### HARVARD MEDICAL SOCIETY

At a meeting of the Harvard Medical Society at the Peter Bent Brigham Hospital on Tuesday, February 14, Dr Elliott C. Cutler presided. Four cases from the medical wards were presented.

The first case, presented by Dr Albert C England, Jr, was a fifty-six-year-old carpenter who came in with a chief complaint of pain in the left chest of four hours duration. When first seen in 1936 for excision of a lipoma of his left thigh, the patient gave a history of some dyspnea and swelling of the ankles. At that time his heart was moderately enlarged and there was a soft systolic murmur over the pulmonic area. Afterward the patient had had attacks of pain in his chest on exertion or emotion, a gnawing constricting substernal pain with radiation. Nitroglycerin gave moderate relief at first. The present entry four weeks previously was preceded by a sudden attack of more severe pain than usual. Physical examination showed nothing new. There were moderate arteriosclerosis, some pulmonary emphysema and slight clinical edema. The blood pressure was 220 systolic, 110 diastolic, an electrocardiogram showed abnormal T waves in all leads. In the hospital he was comfortable in bed with only slight pain.

Dr Robert Monroe in discussing this case mentioned the fact that nitroglycerin was losing its effectiveness. The patient had been much worried, and therefore, sedation had been necessary. The diagnosis was angina pectoris.

Dr Daniel Balad presented the second case, a fifty-five-year-old woman, who entered the second time with the same complaint she had had in October, 1937: mild palpitation, for six years, and dyspnea, for two years. At the time of the first admission, she had had a red-cell count of 1,600,000, a hemoglobin of 15 per cent, a hematocrit of 44, and a red-cell volume of 62 by  $10^{-11}$  cc. Following liver and iron therapy her red-cell count went up to 4,000,000 with 75 per cent hemoglobin. A story of black stools was unconfirmed, a gastrointestinal x-ray series was negative. The patient was discharged on iron therapy. At the present admission she had a red-cell count of 2,600,000 with 26 per cent hemoglobin. She had a 3+ guaiac test on her stools. A hidden malignancy was suspected, but repeat gastrointestinal series and proctoscopy showed no abnormalities. On treatment with iron and ammonium citrate the patient's hemoglobin had gone up.

Because of the microcytosis, Dr Marshall Fulton made a diagnosis of idiopathic hypochromic anemia. He doubted that the gastrointestinal bleeding was the cause. He said that in younger patients the picture would be consistent with chlorosis. Dr Monroe mentioned the relation of chronic blood loss to the premenopausal, postpregnancy period of life, and added that such patients need iron continuously for some reason.

The third case was presented by Dr C F Goeringer. A sixteen-year-old girl, born in Turkey, had come in the day before with the history of a swelling in her neck of two months duration, fatigue, dyspnea on exertion, flushing easily, nervousness and excitability, and a loss of 10 pounds during the past six months. The family history revealed one case of goiter. Physical examination

showed a normal temperature and blood pressure and negative heart and lungs. There was a suggestion of lid lag and tremor of the hands and tongue. There was a symmetrical, smooth, non tender, moderately enlarged thyroid gland, and a suggestion of a bruit. The basal metabolic rate was +25 per cent. Starting two weeks previously the patient had had Lugol's solution twice a day until a few days before entry, with some betterment in symptomatology.

Dr Cutler commented on the patient's pulse rate of 120, the moderate dermatographia and moist, warm hands, and said that he was more in favor of a diagnosis of effort syndrome than one of true Graves's disease.

Dr Goeringer also presented the fourth case, a fifty-five-year-old woman who was admitted for treatment of a carbuncle of the neck, but whose important though not troublesome symptoms were a brassy unproductive cough of ten years' duration, difficulty in swallowing and occasional substernal pain of three years duration, and in definite dyspnea on exertion without signs of decompensation. Two years previously she had begun treatment at the luetic clinic on the basis of a positive blood test and an x-ray examination which had revealed an aneurysm of the ascending aorta. Physical examination showed her pupils to be regular and equal, the trachea in the midline, a tracheal tug and pulsations in the second right interspace. There was no shock or thrill. Retromammary dullness was increased to 12 cm. There were some signs of compression of the lung under the right clavicle. The heart was slightly enlarged to the left, and there was a systolic murmur heard along the left sternal border and in the left axilla.

Dr Cutler commented on her lack of complaint. Treatment had been instituted for the sake of the occasional substernal pain. The diagnosis was aneurysm.

The remainder of the evening's program consisted of a talk by Dr Reginald Fitz, the title of his dissertation being *Forsan et Haec Olim Meminisse Juvabit?* which he ultimately translated as 'Every so often, for all of us, it is nice to remember things in the past.'

By the narration of a dream, Dr Fitz skillfully transferred himself and the audience back to February 14, 1898, in Baltimore at a clinic presided over by Dr William Osler. The first case was presented by a medical student, Mr Fulton, now Dr Frank Fulton. The patient complained of precordial pain. Dr Osler examined the patient himself and noted a sixty-six-year-old man resting comfortably in bed, without dyspnea. He had a slow steady pulse, and beading of the peripheral arteries. The heart was normal except for a slightly accentuated aortic second sound. Dr Osler then commented on the rareness of the syndrome of angina pectoris in the hospital wards of the time, and went into its history. Heberden in 1768 wrote the first account of angina pectoris, and his work still stands out, even at the present day. Matthew Arnold described his own case—a most valuable record by an intelligent man. He wrote of the pain on uphill walking or exercise. His pain became much worse when he made a visit to America, being without friends and under a strain. During a picnic in the Berkshires, his boat capsized, and the sudden attack of pain almost killed him. When Arnold returned to England and his friends, the pain almost disappeared, even to the point of allowing him to play tennis. Finally one sudden severe attack was followed three days later by his death. Allan Burn, in 1809, propounded the theory that angina pectoris was probably due to coronary disease, and he called it intermittent claudication.

The second case was that of a nineteen-year-old girl who had become quite familiar to the clinic by repeated

## REPORT OF THE ADVISORY COMMITTEE ON SYPHILIS CONTROL

The committee presents the following reports received from Dr. Roscoe L. Mitchell, assistant director of the State of Maine Department of Health and Welfare

During the year the director of the division gave thirty six lectures mostly to lay persons on the subject of venereal disease, the total attendance being about 3300 persons. About 800 pieces of educational literature were sent out in response to requests

The Diagnostic Laboratory performed 19,080 Kahn tests and 17,658 Hinton tests. Examinations for the presence of gonococci totaled 5827, 162 of these being performed at the branch laboratory in Caribou

No record is available of the number of syphilis treatments given by private physicians. The Bureau of Health receives reports from the twenty-seven state clinics, and their totals for the year 1938 were 11,846 doses of arsenicals and 12,948 doses of heavy metals

During 1938, 58 per cent of the newly reported syphilitic patients were attending the clinics, whereas 60 per cent of the new cases of gonorrhea were being treated by private physicians

Case reports give a total for 1938 of 588 cases of gonorrhea, 487 being acute, 90 chronic and 11 not stated. Five hundred and seventy two cases of syphilis were reported, the stages being as follows: 95 primary, 139 secondary, 289 tertiary, 36 congenital, 8 latent and 5 not stated

Free drugs of all sorts were issued by the bureau to 130 physicians, exclusive of the material furnished to the state clinics

## MAINE MEDICAL LEGISLATION IN 1939

*L.D. 873* Hospitals must admit osteopaths to practice in them and must do all laboratory work required by osteopaths. Not passed

*L.D. 22* Dr. Pratt's amendment to the Medical Examiners' Bill. Passed in the last week of the session after a very stormy career. Essential changes: number reduced to two each in the counties of Franklin, Hancock, Knox, Lincoln, Piscataquis, Somerset, Sagadahoc and Waldo, three each in Oxford and Washington, four each in Aroostook, Kennebec and York, five each in Androscoggin, six each in Cumberland and Penobscot. The Governor may appoint as many more as he considers advisable, not passed. The law will not take effect until January 1, 1941, that is, after the present Governor retires from office, consequently, the present Governor will not be embarrassed by failure to reappoint.

*L.D. 581* Sale of opium derivatives only on prescription. Passed

*L.D. 472* Sale of barbituric acid derivatives or compounds only on prescription, except for personal administration by a doctor, dentist or veterinary to his own patients. Passed.

*L.D. 820* Dispensation of marijuana forbidden. Not passed

*L.D. 874* Hospitals (and inferentially others) may charge only \$3.00 for x-ray pictures. Not passed

*L.D. 880* United States uniform narcotic law. Not passed

*L.D. 471* Requiring premarital examination for venereal diseases. Amended to require merely a prenatal examination. Requires every physician to take during gestation a blood sample and submit it to the State Laboratory. Passed in this amended form during the last week of the session. Recalled from the Governor's office and had the words added, "and no civil action shall be maintainable for failure to comply with this act." The

law says that the doctor must take the blood test of the patient. To be sure, the consent of the patient is required. But in making a malpractice claim the patient could, and from a previous experience in some instances would, claim that she gave the consent. That the doctor had not taken the test which the law demands could well be claimed to be malpractice. Consequently, this amendment was added to avoid malpractice suits.

*L.D. 606* Lien on casualty insurance proceeds for hospitals. Not passed.

*L.D. 57* Creating office of State Pathologist, earnestly supported by attorney general. Not passed.

*L.D. 537* Compensation Act. Employee may select his own physician in industrial injury. Not passed.

*L.D. 612* Non profit hospital corporations authorized. Not passed

*L.D. 938* Boards of registration, including that of medicine, may suspend the license fees if and whenever there is enough money on hand to warrant it. Not passed.

*L.D. 322* Incorporating the Associated Hospital Service of Maine (socialized hospital service). Passed

*L.D. 600* Optometrist Bill. Forbidding optometrists to practice when hired out, as to chain stores. Stormy career and in doubt up to the end of the Legislature. Passed, but probably ineffective for the purpose it seeks, because the chain stores employing the optometrist will have written contracts with them and probably can by injunction and in equity prevent the operation of the law to defeat their rights under the written contracts

*L.D. 755* To create a licensing department in the hands of one man to take over completely all the powers of the various boards of registration including medicine. Not passed.

*L.D. 811* Permits blood grouping tests in bastardy cases and makes the testimony of the examining physician admissible (heretofore such evidence unacceptable in Maine courts). Passed.

*L.D. 546* Commitment may be made of insane not only to state hospitals, as heretofore, but to government hospitals as well. Passed

*L.D. 1152* Lawsuits to recover for so-called "death without conscious suffering. Right to recover the reasonable expense of medical, surgical and hospital care and treatment" added. Passed. Heretofore in so-called "instant death" cases, that is, those in which the deceased never recovered consciousness after the injury, such incidental expense could not be recovered.

## CORRESPONDENCE

PARKING FOR DOCTORS  
IN A RESTRICTED AREA

*To the Editor* Having been called into court for visiting a patient east of Dartmouth Street before 10 00 a. m., I wrote as President of the Society to Superintendent of Police, Edward W. Fallon, asking if some provision could be made so that doctors visiting their patients in this area, where they are trying to stop early parking, could be worked out. I thought possibly you might like to make some comment in the *Journal*

After giving the matter consideration and consulting Deputy Superintendent John T. O'Dea, of the Traffic Division, he wrote me the following

It is not the aim of the Police Department to interfere in any way with a doctor making a legitimate call to answer any emergency where he is to wait upon the sick, the infirm or the injured and if any such doc

this retreat may be halted and the patient advanced to a better mental status

The "total push" method as used at the McLean Hospital, with the co-operation of Dr Tillotson and his staff, has been carried out for several months on chronic and what appeared to be hopelessly deteriorated schizophrenics. The results have been surprising in the amount of improvement which has been gained physically, socially and, in a narrower sense, mentally. No cure is claimed for this procedure, and in fact, no cure is anticipated. The method, however, shows that the deterioration is not a necessary part of the schizophrenia, and we are gaining insight into the nature of the disease process.

The paper was discussed by Drs Kenneth B Tillotson, Curtis T Prout, John W Thompson and Roy D Halloran.

## NOTICES

### REMOVALS

GUSTAVE B FRED, M.D., announces the removal of his office to 520 Beacon Street, Boston.

HOLLIS L. ALBRIGHT, M.D., announces the removal of his office to 412 Beacon Street, Boston Telephone KENmore 3750

### A WARNING

It has been reported to the *Journal* from a reliable source that a man claiming to be a medical student has entered a hospital and doctors' locker room without permission and stolen a valuable watch. This same man disappeared with money from a person who had befriended him. He goes under the name of Terry Roth or H. Barker, is 23 years old, 6 feet 1 inch, 185 pounds, has light hair, is of Jewish descent, and is hard of hearing in one ear.

Any information concerning this man would be appreciated by the chief inspector, Department of Police, Lynn, Massachusetts.

### TUMOR CLINIC, BOSTON DISPENSARY

Each Tuesday and Friday morning, 10 00 to 12 30, there is a meeting of the Tumor Clinic of the Boston Dispensary, a unit of the New England Medical Center. Neoplasms of various sorts are seen and discussed, and when there is an indication, are treated with radium of high-voltage x-ray. Physicians are invited to visit this clinic. They may bring patients for aid in diagnosis or may refer patients to the clinic following which a report will be returned to the referring physician. A limited number of beds are available for diagnostic study and for treatment.

### SYMPOSIUM ON CARCINOMA OF THE TONGUE

A symposium on carcinoma of the tongue has been arranged by the staffs of the Massachusetts General, Collis P Huntington Memorial, Pondville and Palmer Memorial hospitals. A review of cases seen at each of these hospitals will be presented by Drs. Roy E Mabrey, Ira T Nathanson, Thomas J Anglem and Clifford C. Franseen. Discussion will be opened by Dr Channing C. Simmons.

The meeting will be held on Tuesday, June 13, on the roof of the Palmer Memorial Hospital, at 8 00 p. m. Refreshments will be served.

All members of the medical profession are cordially invited to attend.

LELAND S McHATTRICK, M.D., *Chairman*

## BIOLOGICAL PHOTOGRAPHIC ASSOCIATION

The ninth annual convention of the Biological Photographic Association will be held September 14 to 16 at the Mellon Institute for Industrial Research, Pittsburgh, Pennsylvania. The program will be of interest to scientific photographers, scientists who use photography as an aid in their work, teachers in the biological fields, technical experts and serious amateurs. It will include discussions of moving picture and still photography, photomicrography, color and monochrome films, processing, and so forth, all in the field of scientific illustrating.

This association is prepared to make photographs for physicians and others on a nonprofit basis. Further information about the association and the convention may be obtained by writing the Secretary of the Biological Photographic Association, University Office, Magee Hospital, Pittsburgh, Pennsylvania.

## INSTITUTE FOR THE CONSIDERATION OF THE BLOOD AND BLOOD-FORMING ORGANS

The University of Wisconsin Medical School is to conduct an Institute for the Consideration of the Blood and Blood Forming Organs, September 4 to 6. Formal papers are to be presented by a group of internationally known speakers.

Physicians and others who are interested are cordially invited to attend. A detailed program may be obtained by addressing Dr Ovid O Meyer, Chairman of Program Committee, University of Wisconsin Medical School, Madison, Wisconsin.

## MEDICAL LIBRARY ASSOCIATION

The forty first annual meeting of the Medical Library Association will be held from June 27 to June 29, at the Academy of Medicine of Northern New Jersey, 91 Lincoln Park, Newark, New Jersey. The program will include addresses, discussions, and demonstrations on library procedure, medical history and literature.

JANET DOE, *Secretary*

## SOCIETY MEETINGS AND CONFERENCES

### CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY, JUNE 5

visits. She had come in as white as a sheet, with a red-cell count of 2,000,000. She had chlorosis, a common disease of young working girls living under conditions of hard work, poor air, poor food and little exercise. Sir Andrew Clark was interested in this condition. During his time, methods of treatment were many and various. Given rest, food, fresh air and hygiene, all would get well. One favorite prescription was for tincture of cardamon, which contained the three essentials of good medicine—color, taste and harmlessness. Mr Pratt, now the revered Dr Joseph Pratt, presented some clinical charts on the patient. He showed how the red-cell count had improved with hygienic measures but added that the hemoglobin had not improved until she was given iron in the form of Bland's pills. Dr Osler's comment was that iron is a specific for chlorosis, no matter in what form it be given, so long as it is in large doses. Bland was a local physician, in a town in France, who made a careful series of observations on his patients with chlorosis and then presented his results to the Academy, thus gaining lasting fame.

The third case presented to Dr Osler was that of a young man of twenty-five with an exophthalmic goiter. He had pop-eyes, perspired easily, and was restless. He had a firm smooth symmetrically enlarged thyroid. He had all the other signs of hyperactive thyroid except a rapid pulse. Dr Osler considered the disease to be chronic, and occasionally acute, and said that some acute fulminations led to delirium and severe consequences. Basedow and Mobius and also Joffroy had written about it and noted certain signs that bore their names. Gräfe's sign pertains to lag of the upper lid, Stellwag described widening of the palpebral fissure. These men were all intensely interested in the causes of these phenomena rather than in the disease as a whole. They regarded it as the direct opposite of myxedema. Greenfield described the histopathology of exophthalmic goiter. The only treatment at that time consisted of well-meant measures such as an ice bag to the heart, and perhaps belladonna by mouth. Jones, in 1874, attempted to subdue the hyperactive thyroid by surgery. Dr Osler mentioned surgery as a recent innovation and very risky. William and Charles Mayo had recently reported 12 cases of which 8 had done well and 4 died. In the year 1863 Trousseau made his famous mistake, one of his patients required digitalis, since she had the heart condition associated with hyperthyroidism, but Trousseau, by mistake, prescribed tincture of iodine, ten drops a day, and found to his amazement that the drug led to clinical improvement. With his eyes open, Trousseau tested again, alternating digitalis and iodine and proved his point. Dr Osler spoke of this as probably indicating a better prognosis for such cases in the future.

The last patient was an obviously sick young Negro. The patient had barely managed to walk into the outpatient department, and his history had been taken by young Mr Henry Christian, who presented him to Dr Osler. The thirty-six-year-old patient had given a history of a primary chancre ten years previously, but he had been well until two months before entry when he began having dyspnea, an upper respiratory infection and a 'misery' in his chest. The last few nights he had had to sleep in a chair. Dr Osler then demonstrated by physical examination the visible pulsation in the sternal region, with the trachea displaced to the left, carotid pulsations and cyanosis of the tongue, nailbeds and lips. The patient's breathing was notable in that expiration was longer, louder, and more jerky than inspiration, respiration being mostly abdominal and stridulous. There was a diffuse area of sternal pulsation on the right, and a displaced

thyroid gland with pulsation above the right clavicle. Heart itself was normal. Examination of the lungs showed loud tracheal rales scattered throughout the chest. The patient had a hoarse voice, brassy cough and dyspnea. The diagnosis was obviously aneurysm, probably of the innominate artery. The surgical treatment consisted of ligation of the innominate artery, or perhaps osteotomy of the clavicle and manubrium to relieve tracheal pressure.

At this point Dr Fitz awoke from his dream, and had to follow up these patients. The first patient in a few months had a sudden severe attack, called his family and died quietly a few days later. The last case, the patient with aneurysm, was later demonstrated by Dr Osler at postmortem, and the diagnosis of aneurysm of the innominate artery was confirmed. Dr Osler bewailed their lack of courage in not having operated and ligated the vessel.

Dr Fitz explained, in answer to questions, that he secured his data for 1898 from Dr Joseph Pratt's lecture notes as a medical student. Mr Pratt had taken Dr Osler's lectures almost verbatim.

## NEW ENGLAND SOCIETY OF PHYSICAL MEDICINE

The New England Society of Physical Medicine met at the Ring Sanatorium and Hospital on March 15 following a dinner served to members and guests. The program was presented at Hambury Hall. Dr Abram Myerson, director of research, Boston State Hospital, presided. The meeting on Combined Physiotherapeutics and Motivation in the Treatment of Chronic Schizophrenia.

Dr Myerson said that the general principles underlying the treatment of the chronic schizophrenic by what he called the 'total push' method are (1) That mind and body are one and that mental functions can be profoundly influenced by bodily states, and vice versa, and that division of the individual into mind and body is only a convenience and not a scientific reality. The skin of the body, naturally a place of meeting of the organism with the stimuli which pour in on it, and the muscles, which express the activity of the organism and in particular convey and discharge emotional states, have especial importance in all physiotherapeutic, psychotherapeutic relations. (2) That men live in an atmosphere of praise, blame, reward and punishment, which are the most powerful social motives for conduct and for the inhibition of conduct that exist, aside from the natural hereditary constitutional drives. (3) That use and disuse of function plays an important role in the building up of personality and character, and where functions are non-used, this creates not only atrophy but a lop-sided development of personal and character.

The chronic schizophrenic is by virtue of his disease alone a person in retreat, and this retreat is associated with delusions, especially of reference, persecution and inferiority, with corresponding disorder of physical functioning. In the hospital to which he is sent, unless a continued effort is made regardless of his own co-operation, this retreat is enhanced, since he lives in what is designated as a physiological and motivational vacuum, by which his retreat is furthered and deterioration develops. It is the theory of this 'total push' method that the deterioration is an artificial product, that schizophrenia is not so profound a disorder as it seems, and that by using available physiological and psychological measures in a organized, consecutive, day-by-day, and hour by hour method, with liberal administration of praise, blame, reward and, in so far as it is humanely possible, punishment

## THE HEART IN ANEMIA\*

LAURENCE B ELLIS, M.D.,† AND JAMES M FAULKNER, M.D †

BOSTON

OXYGEN transport to the tissues is dependent both on the proper functioning of the cardiovascular apparatus and on an adequate level of hemoglobin in the circulating blood. The heart and the peripheral circulation act as the propulsive and distributive forces for this function and the hemoglobin as the vehicle. Hence any marked insufficiency in the hemoglobin throws a burden on the circulatory apparatus, and this additional strain may result in clinical symptoms and signs referable to the heart and peripheral blood vessels.

Clinical observations concerning the various effects of severe chronic anemia on the heart have been made and reported many times for at least a century. For the most part these observations have dealt with a few cases only and have been concerned with the findings made during the anemic phase and not when the blood level had been restored to normal. We have therefore made clinical observations on a series of 47 patients with severe chronic anemia (hemoglobin levels varying from 8 to 57 per cent) in 19 of whom the anemia was of the hyperchromic variety, and in 28 of whom it was hypochromic. Thirty-one of these cases have also been studied when the anemia had been partially or completely relieved. None of the patients had any definite evidence of heart disease except that many of them fell into the older age group and therefore inevitably had degenerative vascular disease to a greater or lesser degree. Observations were made of the size of the heart, the occurrence of murmurs, the arterial blood pressure and electrocardiographic changes, together with signs and symptoms referable to disturbance of circulatory function,

and these observations were correlated with the degree of the anemia.

### CARDIAC ENLARGEMENT

As long ago as 1857 Bamberger<sup>1</sup> mentioned that cardiac enlargement might be found in conjunction with anemic conditions. Subsequently numerous observers<sup>2-9</sup> have found enlargement in a varying percentage of cases of severe anemia. Gautier<sup>10</sup> in 1899 demonstrated such an increase in size by the percussion method in 20 of 22 patients, and showed that the heart became smaller when the anemia was relieved. Ball<sup>11</sup> was the first to show such an increase in heart size by x-ray measurements with reduction to a normal diameter after recovery from the anemic state. Others,<sup>12-14</sup> have since confirmed this finding and shown that this return to a normal size may occur within a very few weeks.

We have studied the cardiac size of 38 cases of chronic anemia by teleoroentgenographic measurements. Twenty of these patients had enlarged hearts. There was a tendency for enlargement to occur more frequently in patients with particularly low hemoglobin levels. There also appeared to be some correlation between the age of the patients and the frequency of enlargement. Of the 22 patients under fifty, with an average hemoglobin level of 36 per cent, 8 showed enlargement, whereas of the 16 patients fifty or over, with an average hemoglobin level of 39 per cent, 12 showed enlargement and 4 had none. There was no relation between the type of anemia and the occurrence of enlargement. Although it is probable that the duration of the anemia and the degree of physical activity in which the patient engaged, as well as dietary deficiencies other than that which produced the anemia, may have been of importance as predisposing to cardiac enlargement, our data did not permit us to evaluate such factors. None of the patients, however, had any other clinical evidence of vitamin deficiency.

From the Thorndike Memorial Laboratory, Second and Fourth Medical Services (Harvard), Boston City Hospital, and the Department of Medicine, Harvard Medical School, Boston.

In part the material for this paper was presented before the American Society for Clinical Investigation, Atlantic City, May 6, 1935, and in part before the combined clinical meeting of the Massachusetts Medical Society, Boston, June 1, 1938.

### BOOK REVIEWS

*Emotions and Bodily Changes A survey of literature on psychosomatic interrelationships, 1910-1933* H. Flinders Dunbar Second edition. 601 pp New York Columbia University Press, 1938 \$5.00

The first edition of this book appeared in 1935. This edition has not materially changed the character of the book, but there is some additional material and particularly a long introduction by the author in which she advocates the development of centers for psychosomatic study, staffed by experimental physiologists and clinicians. The book is made up of a critical bibliography, extensive in character, and apparently covering practically all the literature in its 2300 references. There are critical digests of this literature, most of them comparatively short. These have been integrated into chapters covering subjects such as acute and chronic illness, metabolism, diseases of the various systems of the body, and therapeutic considerations. In general, this is a reference book of value to scholars working in this field. It is not a book that will be of much value to the general practitioner. With the knowledge that the author possesses, however, a series of essays on her chapter headings, based on the bibliography, would be of great value to the medical profession. As it is now, the material is so diffusely presented that no conclusions can be drawn in regard to the actual importance of the research that is being reported.

*Medical Information for Social Workers* Edited by William M. Champion. 529 pp Baltimore William Wood & Co., 1938 \$4.00

This book consists of a series of chapters written by nine physicians who have given courses of instruction at the School of Applied Social Diseases at Western Reserve University. It is designed to interest and instruct those who are engaged in the study of social work.

It is evidently the belief of these lecturers that all people engaged in this occupation should have a broad knowledge of medicine and disease in order to supplement the work of physicians in dealing with those patients who are found to have complications of a personal or environmental nature which may prevent a return to useful and enjoyable life.

Most of the important diseases are considered, but with

out any attempt to induce these social workers to take over the work of physicians, but rather to teach people the importance of relying on well qualified practitioners. Emphasis is given to the useful field open to these workers in dealing with the problems of community life and public health.

The book is well written and conveys a great deal of useful information which will interest young doctors. Indeed the busy practitioner could, in many cases, profit by perusal of it. Many of the chapters convey information which the laity may also read with profit—especially that telling how to select a physician. The reviewer found nothing to criticize in this book and felt repaid for the time devoted to it.

*Petite Chirurgie et Technique Médicale Courante* G. Roux. 591 pp Paris Masson et Cie, 1938 90 Fr fr

This book is intended as a text for senior students and as a practical reference volume for the general practitioner. It fulfills its purpose admirably, covering the fields of minor surgery, gynecology, urology and otolaryngology, as well as those procedures which in English speaking countries generally fall within the domain of 'medicine'. Typical Gallic orderliness and precision are reflected in the careful discussions of indications, contraindications and technique which accompany the presentation of each diagnostic or therapeutic procedure. No drug or medicine is mentioned without complete directions for its preparation, a practice which could well be adopted more often by American authors. There is a profusion of unusually fine and pertinent line drawings.

The book should enjoy a wide popularity in France and could be read with profit by the English-speaking student, intern or practitioner.

*Diagnostic Roentgenology* Renewal pages 1938 292 pp New York Thomas Nelson & Sons, 1938

Short additional contributions to original articles appearing in the first issue of *Diagnostic Roentgenology* have been made as follows.

- Diseases of Skull and Intracranial Contents Dr Cornelius G. Dyke.
- Paranasal Sinuses and Mastoids Dr G. W. Grier
- Radiology of the Chest Dr Coleman B. Rabin
- Cardiovascular System Dr Hugo Roesler
- Digestive Tract Dr Ross Golden.
- Diseases of the Bones Drs. Paul C. Hodges, D. B. Phemister and Alexander Brunschwig
- Diseases of the Urinary Tract Drs Leopold Jachs and Marcy L. Sussman.
- Uterotubography Drs Samuel A. Robins and Albert A. Shapira.
- Obstetrics Drs Howard C. Moloy and Paul C. Swenson

New chapters have been added as follows

- Dental Roentgenology Dr Leroy M. Ennis.
- Soft Tissues of the Air and Food Passages of the Neck. Dr Barton R. Young
- The Abdomen Dr Ross Golden.

The entire subject matter is well handled, the book is profusely illustrated, and the contributions are up to date. This text should prove to be a valuable reference book not only for the physician specializing in x-ray but also for the general practitioner of medicine.

when Friedreich<sup>13</sup> first commented on the occurrence of such a murmur in a case in which autopsy subsequently proved that the valves were normal.<sup>13 22-25</sup> The usual diastolic murmur which is heard is early and blowing in character, and is best made out in the third left interspace near the sternal border. It is generally spoken of as aortic, and is thought to be due to functional aortic regurgitation secondary to cardiac dilatation. However, it may be that some at least of these murmurs are in reality due to a functional insufficiency of the pulmonary valve. Although Goldstein and Boas<sup>9</sup> report an incidence of 10 per cent of these murmurs in 39 cases of anemia, this is a very much higher incidence than that generally reported and than that which we have encountered. The murmurs occur only in association with very severe grades of anemia. The only patient in our series who exhibited a diastolic murmur of this type was a young woman of thirty-five suffering from pernicious anemia, with an initial hemoglobin level of 8 per cent and marked cardiac enlargement as judged by percussion measurements. With improvement in the anemia the murmur promptly disappeared and the heart size decreased. A check-up six years later showed the heart to be normal in every respect and the murmur to be still absent.

*Presystolic apical murmurs* in anemic patients have also been described,<sup>9 13 26 27</sup> and undoubtedly do occur. We ourselves have never encountered a true presystolic crescendo apical murmur in an anemic patient which was not clearly due to organic disease of the mitral valve. It is true that one not infrequently obtains a deceptive impression of a presystolic murmur due to a booming first sound or a presystolic gallop in anemic patients as well as in other persons whose hearts are overactive. This is seen especially in thin-chested individuals following exercise and in excited persons as well as in pregnancy and hyperthyroidism.

#### ARTERIAL BLOOD PRESSURE

Reports<sup>13 14 28 29</sup> concerning the effect of severe chronic anemia on the arterial blood pressure are in general in agreement that there is a tendency for a lowering of the systolic and diastolic pressures, and an increase in the pulse pressure in the milder cases while in the more severe the latter may be lowered. Of the 23 patients followed in our study 10 showed an increase in the systolic pressure of 10 mm of mercury or over and in 14 the diastolic pressure increased 10 mm or more following improvement of the anemia. Twice the systolic pressure decreased 10 or 15 mm, but in no case was there a significant drop in the diastolic. In 12 cases improvement was accom-

panied by a decrease in pulse pressure, in 8 no change occurred and in 3 there was an increase. A patient whose initial blood pressure was 125/60 had an increase to 190/115 as he improved, and in another case the pressure rose from 132/55 to 180/60.

The factors chiefly responsible for a diminution in blood pressure are a compensatory peripheral vasodilatation, decreased blood viscosity and a blood volume which, while usually within normal limits,<sup>30</sup> is in the lower range of normal and often less than the blood volume of the patient when his anemia has been relieved. The increased cardiac output occurring during the anemic phase tends, of course, to increase the systolic pressure, and therefore plays an important part in preventing the systolic pressure from falling even lower.

#### ELECTROCARDIOGRAPHIC CHANGES

Most of the published reports<sup>12 13 29 31-33</sup> concerning the effect of anemia on the electrocardiogram conclude that no striking electrocardiographic changes are to be noted. Tung et al.<sup>13</sup> state that prolongation of the Q-T interval may occur, as well as other minor changes, and Elliot<sup>34</sup> found a flattening of T<sub>1</sub> in an anemic patient suffering from angina pectoris in whom autopsy showed the heart to be normal. Zimmermann<sup>35</sup> found that low amplitude and T-wave abnormalities were occasionally present in patients with severe anemia who had angina pectoris, but did not follow them after improvement in order to see whether the electrocardiographic changes had disappeared.

It has been observed<sup>1</sup> in dogs rendered acutely anemic by massive hemorrhage that at systolic-blood-pressure levels in the vicinity of 40 mm of mercury, changes in the electrocardiogram occur which suggest an inadequate coronary blood flow, and that these changes can be promptly eliminated by raising the blood pressure through the infusion of blood or saline solution. Although in several human cases of profound shock and acute hemorrhage, in 1 of which no blood pressure was obtainable, we found the electrocardiogram normal except for tachycardia, in a number of cases of severe chronic anemia we observed electrocardiographic changes which promptly disappeared with the return of the blood toward normal.

Electrocardiograms were taken in 45 of the 47 cases in the group, and in 10 abnormal records were found. The electrocardiograms were repeated in 29 cases. Of the 7 cases in this group which were abnormal at the outset, 5 returned to normal coincidentally with improvement in the blood picture. In one of the 5 the abnormality consisted of an A-V nodal rhythm, a finding which has

Measurements of the cardiac size both before and after successful treatment of the anemia were made in 26 cases. Eighteen of these showed a definite decrease in size of the heart shadow (varying from 10 to 47 cm in the transverse diameter), and in 8 there was no essential change. The greater the degree of the anemia the more likely was the heart to decrease in size following improvement, which is natural since such patients were more prone to have initially enlarged hearts. The changes observed took place within a period of three to twelve weeks in most cases, although in a few cases the second observation was not made until a longer time had elapsed. In 7 of the patients with initial enlargement the heart had decreased to normal size at the time of the second observation, and the hearts of 6, though smaller, were still above the upper limits of normal. Five patients whose hearts were normal in size at the outset showed a decrease after improvement. In none of the 8 patients whose hearts remained unchanged in size was there an initial enlargement.

A third check-up of the cardiac size months or years after the second examination was made in 8 cases. Of the 3 patients whose hemoglobin level remained unchanged, one showed a further decrease in heart size. Five showed continued improvement in their blood, and in 2 of these the hearts had grown still smaller.

An important factor in aiding the return of the heart size toward normal in our patients is the fact that for the most part during the period of treatment of the anemia they were either kept in bed or lived a bed-and-chair existence on the hospital wards, whereas prior to the discovery of their anemias most of them had been engaged in a much greater degree of activity and had thus subjected their hearts to much more strain.

It is evident from the comparatively rapid decrease in size of the heart that may occur that such enlargement must be due at least in part to dilatation. Cardiac hypertrophy, however, has also been shown to take place. Cabot and Richardson<sup>15</sup> found from autopsy study that there was increase in heart weight in 18 of 19 patients dying of pernicious anemia. In 1 case the heart weighed 710 gm. Porter<sup>12</sup> observed a heart weighing 630 gm in a man dying of hookworm anemia. Numerous experiments on animals bearing on this point have been made, the majority of which<sup>16, 17</sup> have given evidence of cardiac hypertrophy as the result of profound anemia. It is Porter's belief that anemia of short duration results in cardiac dilatation which can be completely overcome with relief of the anemia, but that in cases of long duration hypertrophy takes place and thus can never be completely reduced. The

belief of some of the older clinicians<sup>3</sup> that anemia may lead to permanent organic valvular disease is not now accepted.

In addition to dilatation and hypertrophy, the anemic heart muscle undergoes a form of fatty degeneration which has long been familiar to pathologists.<sup>18, 19</sup> The characteristic yellow streaking clearly visible on the endocardial surface has given rise to the term "tigering." These histologic changes are comparable to those observed in experimental animals subjected to low oxygen pressures for long periods.<sup>20</sup>

#### CARDIAC MURMURS

That *systolic murmurs* develop frequently in patients suffering from anemia has been recognized for nearly a hundred years,<sup>1, 2, 4, 5, 7, 21</sup> and is commented on in almost every textbook discussion of the causes of murmurs. Of 46 patients studied by us, 32 had systolic murmurs of varying intensity. The incidence of maximum intensity was divided equally between the pulmonic area in the second or third interspace to the left of the sternum and the apex of the heart. However, since the murmur, when intense, is often audible over the entire precordium it may be difficult to determine whether one is dealing with a single murmur emanating from the pulmonic or mitral area or with the fusion of two murmurs arising from these areas. Both murmurs are high-pitched and blowing in character.

The causative factors for the production of systolic murmurs differ according to their location. In any condition in which the velocity of blood flow is increased a pulmonic systolic murmur is common. This is true following exercise, in pregnancy and in hyperthyroidism as well as in anemia. Hence the pulmonic systolic murmur of anemia might well be associated with an increase in the velocity of the blood, although the exact mechanism of its production is not clear. The apical systolic murmur may be due to a functional mitral regurgitation secondary to dilatation. The presence and intensity of systolic murmurs in our cases were roughly proportional to the amount of cardiac enlargement and to the severity of the anemia. Nineteen of the cases were followed, in 14 the murmur became less marked or disappeared as the anemia improved. Fourteen of these cases were also followed by serial x ray films, in 9 of the 10 in which there was a decrease in the murmur the heart size also diminished, whereas all 4 patients without change in murmur also showed no change in heart size.

*Diastolic murmurs* heard in conjunction with anemia are much less common than systolic, although their existence has been noted since 1861,

probably a relatively slow one, and one which would be likely to cause the improvement in the electrocardiogram to lag behind the improvement in the hemoglobin level.

#### CONGESTIVE HEART FAILURE

Most patients with severe anemia complain of symptoms many of which are similar to those present in persons with impending or actual heart failure. Thus, dyspnea on exertion, palpitation

#### ANGINA PECTORIS

Several authors<sup>32 34 35 42 44</sup> have commented on the occasional occurrence of angina pectoris in patients with anemia. In our present series there is 1 such case and we have encountered several others at various times. The case record of the patient in this series is as follows:

H. L., a 65 year-old English artisan, had been followed at the Boston City Hospital since 1927 for pernicious

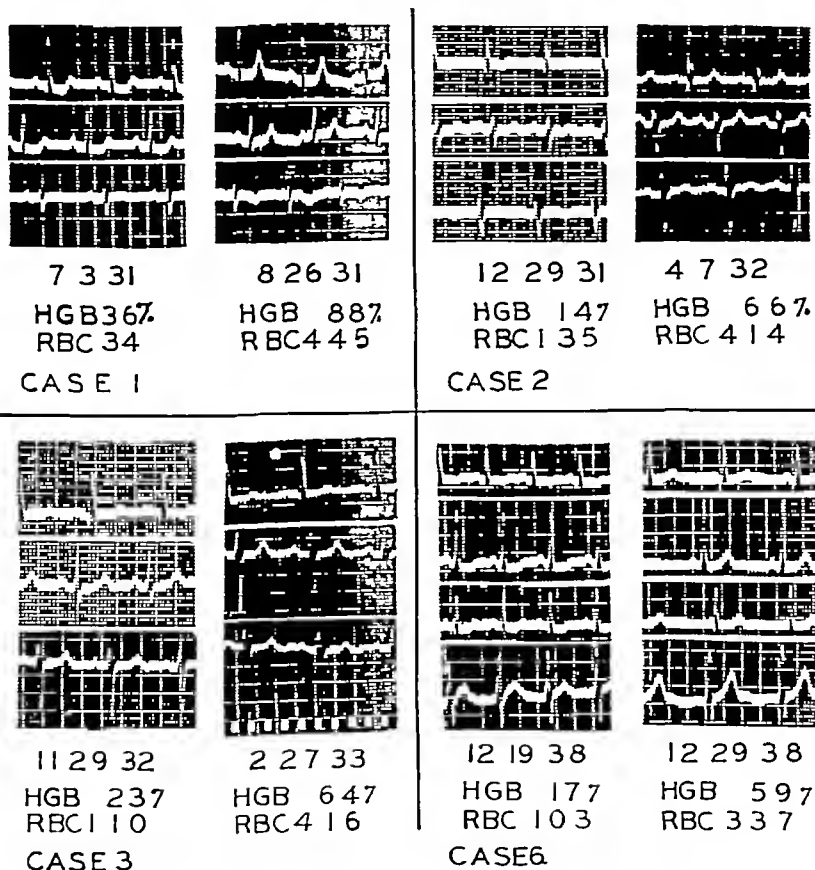

FIGURE 1 Electrocardiograms from Cases 1, 2 and 6 (hypochromic anemia) and Case 3 (pernicious anemia)

and dependent edema are of frequent occurrence. Of our 47 patients, 35 suffered from dyspnea on exertion of varying degree when first seen. Interestingly enough, the occurrence of dyspnea could not be correlated with the degree of anemia, nor did it bear any relation to age. In all the cases followed, the dyspnea improved markedly as the anemia was relieved. Twenty-one of our patients also had dependent edema, usually slight. The edema and dyspnea did not necessarily coexist. Ten of the 12 patients with edema who were followed were completely relieved of it as the blood level returned to normal.

anemia. He had done well under liver treatment until August, 1931, at which time his physician told him that he had high blood pressure and hardening of the arteries and should eat no meat. He thereupon discontinued his liver and shortly thereafter began to experience increasing weakness, easy fatigue and dyspnea on exertion. Early in January, 1932, he commenced to develop typical angina pectoris, that is, squeezing precordial pain radiating down both arms, accompanied by a sensation of smothering and occurring on exertion especially in the cold air, and relieved by rest and nitroglycerin. As time went on this pain was brought on by less and less exertion. In early March there developed slight edema of the ankles and a sore tongue. The patient entered the hospital on March 21, 1932.

On physical examination the positive findings were a

been observed in experimental anoxemia.<sup>37</sup> The other 4 cases showed consistent changes in the T waves which could hardly be attributed to coincidence, to these we have added 4 similar cases which have come under our observation since the original study was concluded. The blood findings and corresponding electrocardiographic changes are shown in Table 1 and Figures 1 to 5

of varied etiology, and none of the electrocardiograms exhibited the sign so frequently encountered in this deficiency, namely prolongation of the Q-T interval. Furthermore, the electrocardiographic abnormalities appeared to be related to the degree of the anemia. The transient nature of the T-wave changes indicates that they were not due to any irreversible myocardial damage, and it

						12	40	1.75	T <sub>1</sub> flat T <sub>2</sub> T <sub>3</sub> voltage increased
						17	47	2.06	T's normal

The highest hemoglobin found in association with an initial abnormal electrocardiogram was 36 per cent, occurring in 1 case, in all the other cases the hemoglobin was 25 per cent or less. In the entire group there were 11 patients with initial blood levels of 25 per cent or less. Seven of these had abnormal electrocardiographic records which became normal as the anemia improved and in 1, although the record was within normal limits, there was considerable increase in voltage with improvement in the blood picture.

A fairly consistent pattern runs through these records, namely a depression of the S-T segment and flattening or inversion of the T wave in Lead 1 or both Leads 1 and 2. Although this pattern is similar to that produced by digitalis, the latter factor was ruled out in every case. The possibility of vitamin B deficiency is more difficult to exclude, since all the patients were suffering from chronic illness. However, none of them showed other signs of vitamin B deficiency, the anemias were

is quite possible that myocardial anoxia would account for them. Certain experimental and clinical studies have been made which indicate that myocardial anoxia produces changes of this nature in the electrocardiogram.<sup>23-42</sup> It is unlikely that cardiac dilatation alone would account for them although in the only 2 cases with abnormal electrocardiograms in which satisfactory x-ray measurements of the heart were obtained before and after treatment, pronounced dilatation was present, as evidenced by a decrease in the transverse diameters of the heart of 2.9 and 2.3 cm respectively. The level of hemoglobin at which myocardial anoxia occurs in an individual case logically depends on the adequacy of the coronary circulation. This would account for the tendency noted in this series for electrocardiographic changes to be found more commonly in older patients. It is possible that fatty changes in the myocardium also have an effect on the electrocardiogram. This also is presumably a reversible change, although

probably a relatively slow one, and one which would be likely to cause the improvement in the electrocardiogram to lag behind the improvement in the hemoglobin level

#### CONGESTIVE HEART FAILURE

Most patients with severe anemia complain of symptoms many of which are similar to those present in persons with impending or actual heart failure. Thus, dyspnea on exertion, palpitation

#### ANGINA PECTORIS

Several authors<sup>22 34 35 43 44</sup> have commented on the occasional occurrence of angina pectoris in patients with anemia. In our present series there is 1 such case and we have encountered several others at various times. The case record of the patient in this series is as follows:

H. L., a 65 year-old English artisan, had been followed at the Boston City Hospital since 1927 for pernicious

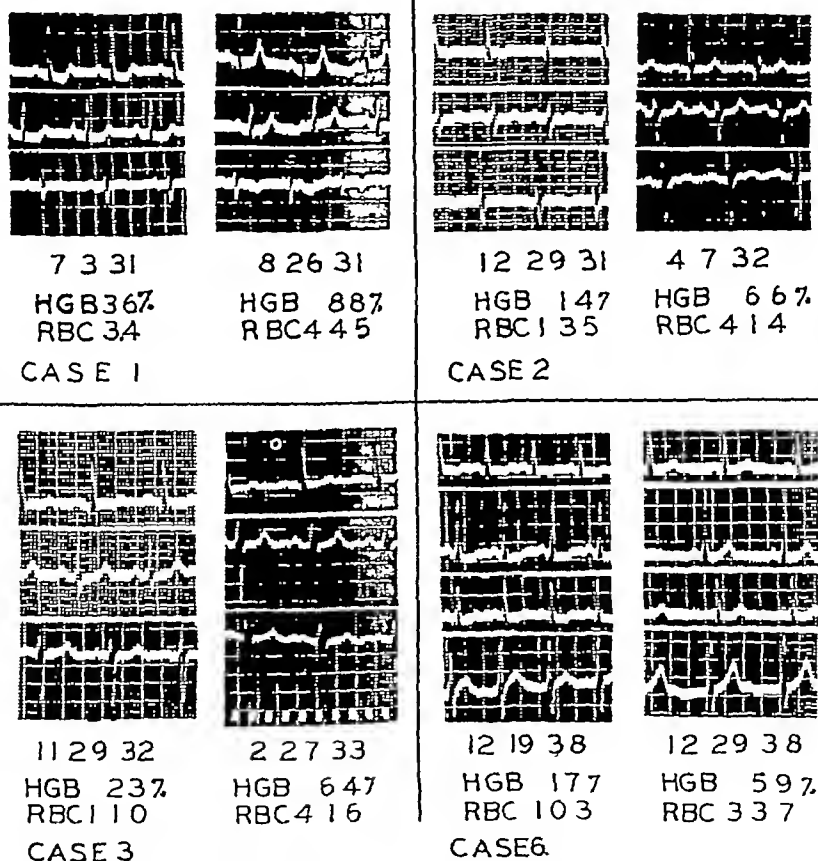

FIGURE 1 Electrocardiograms from Cases 1, 2 and 6 (hypochromic anemia) and Case 3 (pernicious anemia)

and dependent edema are of frequent occurrence. Of our 47 patients, 35 suffered from dyspnea on exertion of varying degree when first seen. Interestingly enough, the occurrence of dyspnea could not be correlated with the degree of anemia, nor did it bear any relation to age. In all the cases followed, the dyspnea improved markedly as the anemia was relieved. Twenty-one of our patients also had dependent edema, usually slight. The edema and dyspnea did not necessarily co-exist. Ten of the 12 patients with edema who were followed were completely relieved of it as the blood level returned to normal.

He had done well under liver treatment until August, 1931, at which time his physician told him that he had high blood pressure and hardening of the arteries and should eat no meat. He thereupon discontinued his liver and shortly thereafter began to experience increasing weakness, easy fatigue and dyspnea on exertion. Early in January, 1932, he commenced to develop typical angina pectoris, that is, squeezing precordial pain radiating down both arms, accompanied by a sensation of smothering and occurring on exertion especially in the cold air, and relieved by rest and nitroglycerin. As time went on this pain was brought on by less and less exertion. In early March there developed slight edema of the ankles and a sore tongue. The patient entered the hospital on March 21, 1932.

On physical examination the positive findings were a

smooth tongue, moderate sclerosis and tortuosity of the peripheral arteries and poor heart sounds with no murmurs. The chest was emphysematous but there were no rales or abnormal breath sounds. The arterial blood pressure was 140/60. There was no edema. The hemoglobin was 44 per cent (Sahli) and the red blood-cell count 1,550,000. A teleoroentgenogram of the heart showed it to be within normal limits, its transverse diameter being 12.1 cm. and the internal diameter of the chest 29.5 cm. An electrocardiogram was normal.

The patient was given intramuscular injections of liver extract and rapidly improved, so that on discharge, May 14, 1932, the angina was completely gone and there were no other symptoms. At this time the hemoglobin was 63 per cent and the red-blood-cell count 2,300,000.

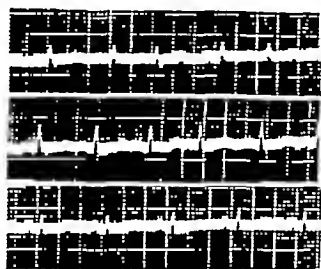

The patient returned for a check up on July 1, 1932 and reported that he had had no recurrence of his angina or any other symptoms. Examination of the heart showed

However, many such patients if relieved of their anemia live for many years with no recurrence of anginal pain.

#### DISCUSSION

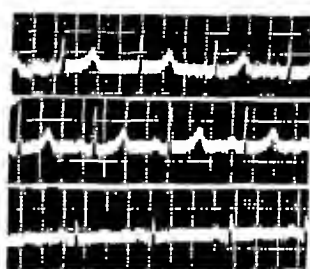

The clinical changes which have been observed to occur in the heart and circulation as the result of severe chronic anemia are all compatible with the alterations in cardiovascular physiology which are known to take place under such conditions.

Normally the oxygen-carrying power of the blood is far in excess of the requirements of the resting tissues, only one third of the available oxygen being removed from the blood in its circulation through the body.<sup>45</sup> It is thus apparent that, if no other compensatory forces come into play, when

3 25 37

FIGURE 2 *Electrocardiograms from Case 4 (pernicious anemia)*

no change. The blood pressure was 130/80, the hemoglobin 80 per cent and the red-blood-cell count 3,400,000. An electrocardiogram revealed no change from the previous one. X-ray examination of the heart demonstrated that the transverse diameter had decreased 1.3 cm. to 10.8 cm. The patient was observed once more on October 11, 1938, 6½ years after the original admission. During this interval the blood had been maintained at a normal level by liver extract, and there had been no angina or other symptoms. Examination of the heart showed no change, the blood pressure was 160/80 and the hemoglobin was 80 per cent. The electrocardiogram showed no change.

Since the cause of angina pectoris is generally accepted to be a disproportion between the need of the heart for oxygen and the available supply through the coronary circulation, resulting in anoxia of the cardiac muscle, it is understandable that this symptom should at times occur in patients with a profound deficiency in hemoglobin and hence in the oxygen-carrying power of the blood. In many cases of angina of this type the patient is of middle age or over and is probably suffering from some degree of atherosclerosis of the coronary vessels, hence the anemia may be considered merely to precipitate the pain in an individual who is already a potential candidate for it.

the hemoglobin falls to about 30 per cent of normal all the oxygen would be taken out of the blood. Actually, although there is an increased oxygen utilization in anemia,<sup>46, 47</sup> it is not necessary that it reach this extreme degree, for there is also a sharp rise in the cardiac output before the deficiency in hemoglobin reaches the level of 30 per cent. Observations have been made on experimental animals<sup>48</sup> as well as on human beings<sup>28, 29, 46, 47, 49-51</sup> which indicate that a progressive increase in cardiac output occurs in severe chronic anemia. The exact point at which this rise first occurs is in some dispute, but most reports indicate that it takes place at a hemoglobin level of about 50 per cent. Dautrebande<sup>49</sup> found in man that the cardiac output may be doubled when the hemoglobin is 30 per cent of normal and tripled when it reaches 20 per cent, although Richards and Strauss<sup>47</sup> did not find so sharp a rise at low hemoglobin levels.

The finding of an increased cardiac output is corroborated by the majority of the reported observations on the effect of anemia on the velocity of the circulation. While Tarr, Oppenheimer and Sager<sup>52</sup> and Porter<sup>12</sup> found very little change from

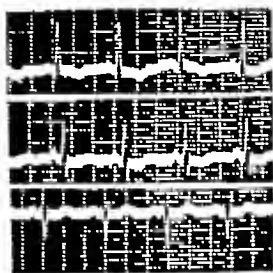

the normal, Bornstein,<sup>33</sup> Blumgart, Gargill and Gilligan,<sup>34</sup> Stewart, Crane and Detrick<sup>29</sup> and Tung, Bien and Ch'u<sup>13</sup> all report an increase in blood velocity which appears to be proportional to the degree of the anemia.<sup>34</sup>

In contrast to the increases in oxygen utilization by the tissues, in the blood velocity and in the cardiac output, there is some decrease in the blood viscosity, and the circulating blood volume,<sup>30</sup> while usually within the limits of normal, is frequently somewhat reduced.

Two theories have been brought forward to explain the cause of the cardiac dilatation which occurs in anemia. One<sup>56</sup> is that it is due to in-

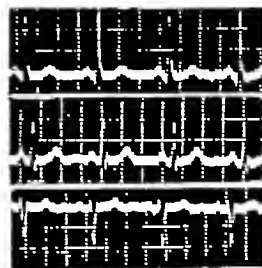

work, and it is possibly these hearts that are most likely to dilate.

In most cases the cardiovascular symptoms of which anemic patients complain, while superficially similar to those of impending or actual congestive heart failure, are not due to primary impairment of cardiac function, and these patients do not have heart failure. The primary deficiency is in the vehicle for oxygen transport, the hemoglobin. The circulation attempts to compensate for this by a greater peripheral oxygen utilization and by an increased minute-volume output of the heart, and does sufficiently compensate so that dyspnea at rest does not

HGB 17% RBC 049

9 21 37

HGB 25% RBC 130

FIGURE 3 *Electrocardiograms from Case 5 (aleukemic myelosis)*

sufficient oxygen supply to the heart itself because of the anemia, the other<sup>5 10 50</sup> is that increased work of the heart occasioned by increased cardiac output is the cause. Stewart et al.<sup>29</sup> deny that the heart in severe anemia is called on to do excessive work in spite of the increased minute-volume output. Since the work of the heart is as dependent on the level of the blood pressure as it is on the cardiac output,<sup>56</sup> these investigators found in their cases that, because of the lowered blood pressure, the calculated work of the left ventricle was no greater and often less during the anemic phase than at a time when the hemoglobin level was higher and the cardiac output less. It is, however, hazardous to apply their conclusions to all cases of anemia, for it should be noted that the blood-pressure changes in Stewart's cases were greater than in most of our cases with comparable changes in the blood level, and, moreover, the heart measurements of his patients were little if any increased above normal and showed very little decrease as the anemia improved. It is quite probable, therefore, that the hearts of anemic patients in whom there is comparatively little lowering of the blood pressure are obliged to do an increased amount of

work, and it is possibly these hearts that are most likely to dilate. But with the increased demands for oxygen during physical activity this compensation breaks down and dyspnea results. Similarly, the palpitation that occurs is merely the subjective manifestation of the tachycardia which is part of the compensatory response. The edema present is usually due to a low plasma osmotic pressure caused by deficient blood proteins, and is not produced by the increased hydrostatic pressure in the capillaries which takes place in heart failure.

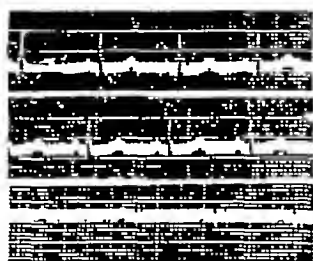

In primary heart failure there is not ordinarily an increase in cardiac output, in fact, the output is almost always normal or diminished, and the important factor is an inability of either the right or left side of the heart or both to expel the blood properly as it reaches it, with a resulting backing-up of the blood in the veins and capillaries of the peripheral circulation or the lungs, increase in venous pressure and loss of fluid into the tissue spaces leading to pulmonary or peripheral edema.

In rare cases, however, congestive heart failure is said to occur in patients with severe chronic anemia even in the absence of demonstrable organic heart disease. We have not encountered such a

case, but Tung et al<sup>13</sup> report 6 cases. When heart failure ensues certain signs become manifest which are not present in the usual patient with anemia. These are pulmonary congestion with rales at the lung bases and the symptoms of orthopnea and cough, and peripheral venous congestion, shown by the distended jugular veins in the semi-recumbent position and enlarged tender liver and by direct measurement of the venous pressure.

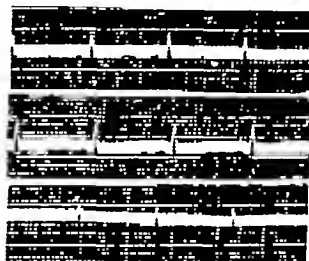

Whether heart failure ever occurs in anemic patients without some additional burden or causative factor is doubtful, and difficult to determine. Tung mentions that extra physical demands such as marked physical exertion, fever

Although the physiologic effects on the circulation of primary heart failure and of anemia are thus different, the clinical symptoms and signs are frequently closely similar. Dyspnea, palpitation and edema and even angina pectoris may occur in both conditions, and in both one may find cardiac enlargement, murmurs, electrocardiographic changes and lowered blood pressure. Only too often physicians erroneously treat cases with unrecognized anemia as those of heart failure. The avoidance of such an error is of course easy if determination of the erythrocyte and hemoglobin levels of the blood is carried out, and clinically suspicion that the case is not one of true heart

FIGURE 4 *Electrocardiograms from Case 7 (pernicious anemia)*

and pregnancy or parturition are important precipitating factors. There are two other possible important causative factors which are difficult to evaluate. The first is the possibility that persons of middle age or over may develop heart disease and failure without a single specific sign's being demonstrable on physical examination of the heart itself or in the electrocardiogram. Hence all patients with anemia in this age group must be considered to have potential heart disease. The second point is that many patients who suffer from a severe grade of anemia, whether hyperchromic or hypochromic, are also suffering from one or more other deficiency states, because of inadequate diet or impaired gastrointestinal function. It is well known<sup>67</sup> that deficiency of vitamin B<sub>12</sub> may produce changes in the heart and circulation resulting in congestive heart failure, and hence it is not improbable that the heart failure which may appear to be due to anemia is in reality caused at least in part, by vitamin B deficiency. Indeed all the cardiovascular manifestations of anemia which we have described may in some cases, and to a greater or lesser extent, be due to the vitamin lack.

failure may be aroused by the absence of evidence of pulmonary and peripheral venous congestion, as shown by the lack of orthopnea and pulmonary rales and of distended neck veins in the semi-recumbent position.

A far commoner mistake is failure to recognize that in the presence of heart disease even a moderate degree of anemia may precipitate cardiac insufficiency. The changes in the circulation produced by anemia add a further burden to the already inefficient and overloaded hearts of such persons with cardiac disease. Not only does the presence of anemia produce a demand on the heart for an additional output of blood at a time when the oxygen supply to the heart is less efficient than normal, but the peripheral circulatory adaptation is also overburdened. Thus the extra load on the circulation of anemia frequently is responsible for initiating congestive failure in patients with heart disease, for aggravating the decompensation and delaying recovery when once failure has occurred, and for precipitating attacks of angina pectoris. It is of particular importance to bear this fact in mind, because of all the factors which may contribute to the occurrence of heart failure, con-

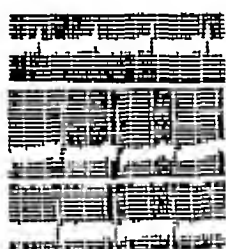

gestive or anginal, anemia is one of the easiest to diagnose and one of the most amenable to treatment

#### SUMMARY AND CONCLUSIONS

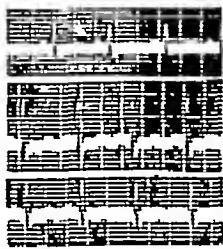

A study is reported on a series of 47 patients with severe chronic anemia without other evidence of heart disease. Thirty-one of these patients were followed after relief of the anemia.

Twenty of the 38 cases whose hearts were studied

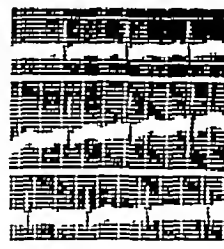

ilar abnormal electrocardiographic findings are cited. With the exception of 1 patient, all the records occurred in patients whose initial hemoglobin levels were 25 per cent or less. One abnormal electrocardiogram consisted of an auriculo-ventricular nodal rhythm, the remaining 8 tended to show a consistent pattern of change, namely a depression of the S-T segment and a flattening or inversion of the T waves in Lead 1 or both Leads 1 and 2.

by x-ray showed cardiac enlargement, and of the 26 who were followed 18 showed a decrease in heart size with improvement of the hemoglobin level.

Thirty-two of 46 patients exhibited systolic murmurs. In 14 of the 19 who were followed the murmur became markedly less or absent. One patient had an "aortic" diastolic murmur which disappeared with improvement.

The anemia tended to produce a lowering of the systolic and diastolic arterial blood pressures.

Of the 45 patients studied by electrocardiogram, 10 showed abnormal records. In a group of 29 patients who were followed, 7 showed abnormal records, of which 5 became normal as the blood level increased. Four additional patients with sim-

The causation of the cardiac abnormalities is discussed and correlated with the clinical symptomatology, and with the changes in the cardiovascular physiology known to take place. It is emphasized that patients with anemia are often erroneously diagnosed as suffering from heart disease, and also that since anemia is an aggravating burden in persons with organic heart disease it is important that it be recognized and treated in such cases.

## DELIRIUM TREMENS A STUDY OF CASES AT THE BOSTON CITY HOSPITAL, 1915-1936\*

MERRILL MOORE, M.D.,† AND M. GENEVA GRAY, PH.D.‡

BOSTON

AT THE Boston City Hospital alcoholism is among the commonest medical diagnoses made. The number of alcoholic patients admitted is conservatively estimated at a minimal figure of 2500 per year (and may actually be 3000 cases or more§), and the expense to the City of Boston of caring for alcoholic persons is variously estimated between \$500,000 and \$1,000,000 per year, not counting loss of earnings due to illness associated with excessive drinking. This figure includes, of course, the cost of care in penal institutions and the handling of alcoholics by the municipal court.

Most striking among these alcoholic patients are those who suffer from delirium tremens. In the period between 1915 and 1935, 2375 persons with delirium tremens were admitted, out of 38,376 alcoholic patients (Table 1). The number varies

Alcoholic cases have constituted approximately 5 per cent of all admissions to the Boston City Hospital in the last seventy years. Among all the alcoholic cases those suffering with delirium tremens constitute an average of 6.2 per cent, though this figure has risen as high as 15 per cent (as in 1918) and was 11 per cent in 1935. The sustained rise shown in the last five years is quite marked.

The increase in admissions because of alcoholism is disproportionate to the growth of the hospital, but the addition of new facilities has enabled it to care for an increasing number of alcoholic individuals.<sup>1</sup> The situation in Boston affecting the hospital care of alcoholic persons has been more or less unique in that no hospital has been entirely willing to accept them for care except in the most acute emergency.<sup>2</sup> It is of great interest to note that the trend in the incidence of alcoholic psychoses in Massachusetts as reported by Guthrie and Dayton and in New York is very similar to that exhibited by the number of admissions to the Boston City Hospital during the same period.<sup>3</sup>

The care of patients with acute forms of alcoholism is a heavy burden when gauged in terms of the nursing and medical attention needed, and this is particularly true when delirium tremens occurs. In this condition the danger of death is great, and the mortality is high because delirium tremens constitutes a major ordeal for the patient's entire system, accompanied or preceded as it may be by intoxication, disturbed nutrition, exhaustion and exposure of various types. Table 2 gives the number of deaths from delirium tremens compared with the total number of patients admitted with delirium tremens to the Boston City Hospital from 1915 to 1935. In this period, 2375 patients with delirium tremens were admitted and 560 (approximately 24 per cent) died. The significance of this finding may be emphasized by noting that over the twenty-one-year period included in this study, the ratio of deaths among patients with delirium tremens varied from 52 to 12 per cent, with an average of 24 per cent. During the last ten years there has been a gradual decrease in the ratio of deaths among cases of delirium tremens admitted to the hospital.

Information concerning the number of deaths

cent. When the deaths among cases of delirium tremens are compared with those among all cases of alcoholism, it can be seen that since 1930 the former have increased very slightly compared with the striking increase of deaths among the latter. Some features of this increase have been commented on by Dr. Timothy Leary,<sup>4</sup> medical examiner of the southern district of Suffolk County, who has shown that deaths due to alcoholism are also increasing in the non-hospitalized population of Greater Boston.

In the last seven years the tendency at the Boston City Hospital has been toward improvement in nursing care, which fact may well have contributed to lowering the number of fatal results among the cases of delirium tremens. A similar decrease has been noted in other clinics. Piker and Cohn<sup>5</sup> state that the mortality in 1910 in one reputable clinic was 37 per cent, but has decreased in the last ten years to 10 or 12 per cent through rational treatment. Since 1842 according to Chadwick,<sup>6</sup> deaths from alcoholism have formed a large group in records of vital statistics in Massachusetts.

In previous studies<sup>7,8</sup> it was shown that men admitted to the Boston City Hospital for alcoholism outnumbered women five to one. An even greater preponderance of men is noted among cases of delirium tremens (Fig. 1). Among all alcoholic

admissions deaths were commoner in the fifth decade for men and in the fourth for women. The sex and age distribution among patients dying with delirium tremens shows the greatest number of deaths among men in the same period, especially between thirty-six and forty years of age. Among women with delirium tremens most deaths occurred in the forty-one to forty-five year age group. Among fatal cases of delirium tremens, the predominance of men over women is very striking, and should be kept in mind in any discussion of the incidence of alcoholism at the Boston City Hospital. It must also be borne in mind that the

figures given can only suggest the magnitude of the problem as it is seen in the hospital, and that the numbers reported are minimal in terms of the total incidence of delirium tremens. They are only a partial index of actual conditions in the

FIGURE 1 *Age and Sex Distribution of Deaths in Patients with Delirium Tremens Admitted to the Boston City Hospital 1915-1936*

community. Even for the hospital these figures do not overstate the problem. As has been stated, many patients who are actually suffering from alcoholism are admitted because of, and are formally

diagnosed in terms of, the complication that occasions their admission to the hospital pneumonia, fractures, digestive or nutritional disturbances, neuritis and so forth. For a long time many patients suffering from delirium tremens and other forms of alcoholism have been necessarily refused admission to the hospital for various reasons. Until 1917 a record was kept of these patients to whom admission was refused (Fig 2), but since 1917

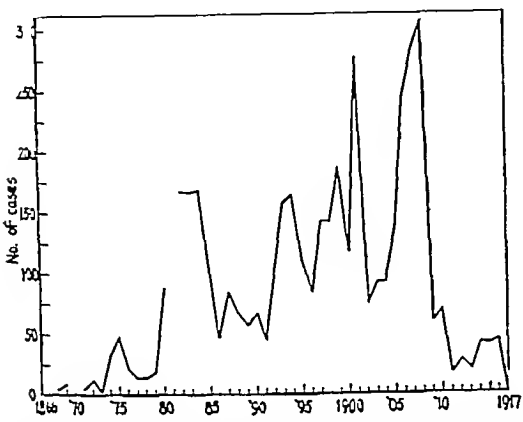

FIGURE 2. Number of Patients Refused Admission to the Boston City Hospital on Account of Delirium Tremens and Alcoholism 1866–1917

detailed information regarding their number has not been available.

Very few patients with delirium tremens die without complications (Table 4). The majority of cases in this series had serious medical and surgical conditions of which terminal pneumonia was the commonest. Dilatation of the heart was often diagnosed in fatal cases. Commonly seen, also, were conditions resulting from head injuries. Many infections occurred, with and without trauma.\*

A medical problem which involves such extensive need for nursing care and medical treatment is deserving of serious consideration by municipal authorities. It is probable that cycles of increased and decreased incidence of alcoholic admissions to general hospitals will continue unless provision for more effective treatment and prevention of alco-

holism is developed. It has frequently been pointed out that the alcoholic personality is distinctly a neurotic one,<sup>13-16</sup> and that the most effective treatment employs psychological and psychotherapeutic measures. A program in preventive medicine and public health is needed in communities faced with this problem, the basic principle of such a program must be the adequate care of the alcoholic personality in the early stages of the condition and as soon as the need becomes apparent.

No program of prevention can succeed unless there is an organized interest in the alcoholic patient as an individual, and a realization that not all such patients<sup>1b</sup> are beyond medical assistance.

SUMMARY

Between 1915 and 1935, 38,376 patients suffering from alcoholism were admitted to the Boston City Hospital, of this group, 2375 were diagnosed delirium tremens. This figure represents a yearly average of about 250 cases or 6.2 per cent of all cases of alcoholism.

There has been in recent years a marked increase in admissions for alcoholism, and this in-

crease has been noted as well among cases with delirium tremens. In 1930, delirium tremens cases among all alcoholic cases constituted 3 per cent and in 1935 11 per cent.

There has been a high incidence of fatal outcome among delirium cases, amounting in the period reported to 560 deaths. Although admissions of patients with delirium tremens have increased in recent years, there has been observed a marked decrease in deaths from 52 per cent in 1915 to 14 per cent in 1935. There has not been a corresponding decrease in deaths among all cases of

An evaluation of the causes of death in cases of delirium tremens is difficult. However two groups seem to stand out, those in which the cause of death was directly related to alcoholism and those in which the relation was only indirect or coincidental. Cases of pneumonia are a complication of delirium tremens although studies by Weichselbaum,<sup>17</sup> Grawitz,<sup>18</sup> and others indicate that alcoholism and the associated vitamin deficiencies cause a diminution in resistance to bacterial infections. Cases with dilatation of the heart are most frequently due to the vitamin deficiency associated with alcoholism which has been proved to be analogous to beriberi heart disease by the studies of Weiss and Wilkins.<sup>19</sup> A large number of alcoholic patients die from direct involvement of the brain due either to the neuritis, pellagra or to Wernicke's disease, both of which conditions may involve the vital centers of the brain including the vagus nucleus. Wernicke's disease may be recognizable grossly particularly if all lesions are associated with hemorrhages, but this cannot be observed in all cases. In the absence of visible hemorrhage, a very experienced pathologist may recognize the bluish-gray discoloration of the periventricular tissue as suggestive of Wernicke's disease. A neuritis of the vagus or the beriberi type can be recognized only microscopically. Advanced neuritis of the vagus nucleus should be accepted as a cause of death, as pointed out by Alexander.<sup>12</sup>

alcoholism in this period. In 1932, the deaths among cases of delirium tremens represented only 7 per cent of all those due to alcoholism, and has varied between this number and a high level of 46 per cent in 1926.

Men predominate among patients dying from delirium tremens at the Boston City Hospital, and are found in a higher percentage in the group suffering a fatal outcome than in the entire group diagnosed as having delirium tremens. Most of the men who died were between thirty-six and forty years of age, and the women were between forty-one and forty-five.

Many persons suffering from alcoholism and delirium tremens have been refused admission to the Boston City Hospital because of lack of facilities for their care. The proper treatment and disposal of these patients is a constant and expensive burden to the city (and the Commonwealth as well), and is worthy of a carefully planned and extensive program which would tend to prevent the serious secondary complications of alcoholism.

## TRANSMISSION OF ENCEPHALOMYELITIS IN THE HORSE AND POSSIBLE VECTORS IN THE HUMAN BEING\*

JAMES STEVENS SIMMONS, M.D.†

BOSTON

IT SEEMS probable that equine encephalomyelitis has existed in the United States for at least a century, and possibly longer, and that it occurred in New England long before the outbreak recognized in the summer of 1938. However, information about the disease has been developed only during the last decade, beginning with the discovery of the Western type of virus by Meyer, Haring and Howitt<sup>1</sup> in 1930. In that year these workers investigated an epizootic of encephalitis which appeared among horses in irrigated districts of the San Joaquin Valley in California. As in our recent local outbreak, the first cases were recognized early in July. The incidence increased gradually throughout August, and reached a peak about the middle of September, when the disease appeared with explosive swiftness in every part of the valley. With the onset of cooler nights there was a rapid decrease and after November the disease disappeared. Infections occurred in California for the next two years, beginning with the hot weather in June or July and, except for sporadic cases ending with cool weather

1930. It was noted that communities affected in 1930 and 1931 were relatively free of the disease in 1932. During the latter years the condition spread over much of the western half of the United States. There was an increase in incidence during the later years of this epizootic, the attack rate being about 10 per cent in 1930, while in 1931 and 1932 it varied in newly infected areas from 20 to 80 per cent. Infection occurred in animals of all ages. The mortality was estimated at about 50 per cent, but it varied in different communities from 25 to 70 per cent.

Because of the failure to find evidence of obvious connection between cases, it was suspected that the disease had been spread by unrecognized carriers. Various other features of the disease suggested the possibility of insect transmission, and experimental attempts were made to transmit the disease through horse flies (*Tabanus punctifer*), but with negative results.

*Isolation of Western Type of Virus* The California workers<sup>1-6</sup> isolated a filterable virus which differed immunologically from the virus of Borna disease, and from the virus of poliomyelitis, which was epidemic in California at that time. They also

\* Presented as part of a symposium on encephalomyelitis at a meeting of the Massachusetts Public Health Association, Boston, November 10, 1938.  
† Lieutenant Colonel, Medical Corps, United States Army Headquarters First Corps Area, B.

described the pathologic lesions of the disease, and suggested the term "equine encephalomyelitis"

*Location of Virus in Horses* These and later studies indicate that in infected horses the concentration of infective virus is greatest early in the disease. Virus was recovered from the cerebrum, pons, medulla oblongata and spinal cord, but not from the liver, spleen or kidneys. It has also been obtained from spinal fluid, and from the cardiac and peripheral blood during the febrile period, but rarely after the development of neurologic symptoms.

*Susceptible Experimental Animals* Using various methods, including cutaneous and intranasal inoculation, the virus has been transmitted to various animals, including horses, mules, guinea pigs, white mice, white rats, rabbits, monkeys and gophers. As a rule the mortality is higher in young animals, and the most valuable diagnostic animals are young guinea pigs and white mice. In 1933 Giltner and Shahan<sup>7</sup> observed that sheep, dogs and cats were resistant, that calves developed the disease, but some recovered, also that after intracerebral inoculation pigeons died in three days, while white Leghorn chickens were resistant. They suggested that calves and pigeons might be concerned in the epizootology of the disease in nature. This possibility is strengthened by the work of Fothergill,<sup>8</sup> who has isolated the Eastern type of virus from a naturally infected pigeon obtained in the region of the recent epizootic in Massachusetts.

*Eastern Type of Encephalomyelitis* During the summer of 1933 a disease resembling the California epizootic was recognized among horses in Virginia, Delaware, New Jersey and Maryland. The clinical symptoms and seasonal distribution were much the same, and the virus was pathogenic for the same species of laboratory animals. However as has been shown by Ten Broeck and his associates,<sup>9-10</sup> this disease, which was designated as the Eastern type of encephalomyelitis, differed as follows: its virus was immunologically distinct, its mortality was higher, and unlike the Western disease it was most prevalent in regions near salt marshes. Others who contributed to our knowledge of the Eastern type include Records and Vawter,<sup>11-13</sup> Giltner and Shahan<sup>7</sup> and others.

*Experiments in Transmission by Mosquitoes* Prior to 1933, nothing definite was known about the transmission of equine encephalomyelitis. However, its epidemiology presented features suggesting that insects might be a factor. These included the seasonal distribution of the disease, its tendency to occur near waterways and swampy lands, its greater prevalence in rural areas among animals

kept in pasture at night, and the lack of evidence of contact between individual cases. Records<sup>14</sup> noted that while the disease could be transmitted experimentally by intranasal instillation, normal horses stabled with infected ones did not contract the disease through contact, or through eating or drinking from the same containers.

During 1933, Kelser,<sup>15</sup> working in the laboratories of the Army Medical School in Washington, discovered that the virus of the Western type of the disease could be transmitted from infected to normal guinea pigs and to horses through *Aedes aegypti*.

In the spring of 1934, other workers at the Army Medical School (Simmons and Reynolds<sup>16</sup>) incriminated *A. albopictus*, which is a common Oriental mosquito and also breeds in houses. This work was done with a colony of *A. albopictus*, started from eggs shipped from Manila and maintained at the Army Medical School for teaching and experimental purposes. While this mosquito is not indigenous here, it is an effective vector of dengue fever and yellow fever, and its incrimination as a transmitter of equine encephalomyelitis may be of practical importance in Oriental countries.

Later in 1934, Merrill, Lacaille and Ten Broeck<sup>17</sup> reported transmission of both the Western and Eastern type of viruses by *A. sollicitans*, and of the Eastern type by *A. cantator*. These are salt-marsh mosquitoes, both of which have been found in Massachusetts (Davis,<sup>18</sup> 1938).

Early in 1935, Madsen and Knowlton<sup>19-20</sup> in Utah transmitted the Western type of virus through *A. nigromaculis* and *A. dorsalis*, and later that year Kelser<sup>21</sup> in New England incriminated *A. vexans*. During 1938 Kelser,<sup>22</sup> working at the laboratory of the Army Medical Research Board in Panama, transmitted Western virus with *A. taeniorhynchus*.

The detailed mechanism of the transmission of the virus by these mosquitoes still requires much study. The work of Merrill and Ten Broeck<sup>23</sup> with *A. aegypti* indicates that to ensure transmission the normal mosquitoes should feed on the infected animal early—or as soon as the animal's temperature reaches 40.5°C, which usually is from eighteen to thirty hours after its infection. After an incubation period of four or five days the mosquito can transmit the virus by biting, and it remains infected throughout its life. Actual tests were made up to three months after infection.

Working with *A. sollicitans*, Merrill and Ten Broeck<sup>24</sup> reported that this mosquito was first able to transmit the disease seven days after feeding on suspensions of infected guinea pigs brains, eleven days after feeding on infected guinea pigs and twenty days after feeding on an infected horse.

These workers also proved that when normal *A. aegypti* were fed with suspensions of macerated infected ones, virus was transmissible directly from one mosquito to another through seventeen passages and probably indefinitely. This may have epidemiological significance.

These preliminary studies implicate eight species of *Aedes* mosquitoes as potential vectors of encephalomyelitis, and it seems probable that additional species of mosquitoes and other insects are also concerned in the natural spread of the disease. In this connection, the recent (1936-1937) discoveries of Syverton and Berry<sup>25-27</sup> are of great interest. They have shown that *Citellus richardsoni*, the gopher or Richardson ground squirrel of the Northwest, is susceptible to the Western type of virus, also that the tick (*Dermacentor andersoni*) may serve as a vector of this virus, which survives in it through all stages of the developmental cycle, including the egg, and has been transmitted by larvae nymphs and adult ticks from infected to normal guinea pigs and gophers.

Thus, in considering the question as to the spread of encephalomyelitis in nature we are confronted with an abundance of known potential vectors, including at least eight species of *Aedes* mosquitoes and one species of tick. Undoubtedly other vectors will be incriminated. We have no exact knowledge concerning lower animal reservoirs of virus, but the available experimental data indicate the need for an extensive investigation of many species of domestic and wild animals and birds.

Because of the unusual prevalence of mosquitoes in New England during the summer of 1938, it is suspected that one or more of the species present were responsible for the epidemic of encephalomyelitis. However, this has not been proved. Adequate information concerning the relative prevalence throughout the year of the different species normally present in this region is not yet

available. Furthermore, in no case has the virus been demonstrated in trapped mosquitoes.

It therefore appears that before one can intelligently discuss the transmission of this disease either among horses or in man, much fundamental investigation must be done.

## REPORT ON MEDICAL PROGRESS

## TUBERCULOSIS

DONALD S KING, M.D.\*

BROOKLINE

THE following subjects have been selected as worthy of comment in a brief review of the important and practical advances in the study of tuberculosis that have been reported during the current year: the present status of the tuberculosis problem in Massachusetts, the importance of searching the gastric contents for tubercle bacilli, the frequency of tuberculous infection of the bronchi and trachea and the results of such infection, the problem presented by latent or asymptomatic tuberculosis with positive x-ray but no symptoms, pulmonary tuberculosis as an occupational hazard in student nurses and medical students, non-caseating tuberculosis—is it the same as “sarcoid disease”?—recent attempts at statistical evaluation of the results of compression therapy, extrapleural pneumothorax—the newest surgical measure for treating pulmonary tuberculosis, vitamins in the treatment of pulmonary tuberculosis, and the use of sulfanilamide in experimental tuberculosis.

## THE TUBERCULOSIS PROBLEM IN MASSACHUSETTS

The death rate from pulmonary tuberculosis in this state continues to fall. In 1937 it was 40.0 per 100,000 population, in 1938 it was 34.9. There are now 4472 sanatorium beds for the treatment of this form of tuberculosis, and for the first time there is no material delay in the admission of the patients to any of the county or state institutions. This is a source of great satisfaction, because regardless of our feelings about socialized medicine in general it is evident that public funds must be used if we are to isolate the open cases of pulmonary tuberculosis which are spreading the disease, and give the patients in the favorable stages the necessary sanatorium treatment.

## TUBERCLE BACILLI IN GASTRIC CONTENTS

The importance of the search of the fasting gastric contents for tubercle bacilli was again called to the attention of the medical profession in papers by Stadnichenko and Cohen<sup>1</sup> and Gourley<sup>2</sup> at the meeting of the National Tuberculosis Association in 1937. It is surprising that these investigators should so often find tubercle bacilli in the gastric contents of children with the apparently benign childhood type of the disease. Since the publica-

tion of these papers examination of the gastric contents has become a routine in many sanatoriums in the study of cases not raising sputum. Again the number of positive reports is surprising. In the recent edition of *Diagnostic Standards* the National Tuberculosis Association insists that a patient is not to be classified as “apparently cured” until, “in case there is no sputum, the fasting gastric content has been obtained and thoroughly examined.”<sup>3</sup>

There is one possible error in this procedure, namely, that harmless acid-fast bacilli may be mistaken for tubercle bacilli. However, guinea-pig inoculations have shown that this mistake occurs in only a small percentage of cases.

## TRACHEOBRONCHIAL TUBERCULOSIS

In the entire field of pulmonary disease one of the most important advances in the last twenty years has been the recognition of varying degrees of bronchial obstruction and its effect on that part of the lungs supplied by the bronchus involved. Three degrees of bronchial obstruction can be recognized clinically if we remember that the normal bronchus widens on inspiration and narrows on expiration: an obstruction so slight that it allows air to enter easily on inspiration but impedes its flow on expiration, causing a wheeze, an obstruction which allows air to enter on inspiration but completely closes the bronchus on expiration and thus traps air in the portion of the lung supplied by that bronchus (obstructive emphysema), a complete obstruction of the bronchus which does not allow any air to enter and results in atelectasis of the lung.

All three degrees of bronchial obstruction are found in pulmonary tuberculosis. Bronchoscopic examination shows that the obstruction in such cases is due to a tuberculous process in the bronchi themselves.<sup>4,5</sup> This process may be a discrete, shallow ulcer, hyperplastic granulation tissue, fibrostenosis, which is the healed stage of the foregoing processes, tuberculoma resembling a tumor, or obstruction by a tuberculous gland pressing on the bronchus or ulcerating through its wall. Bronchoscopists estimate that in 10 per cent of all cases of pulmonary tuberculosis there is an associated tuberculosis of the bronchi. Occasionally the tuberculous infection is limited almost entirely to the

\*Associate in medicine, Harvard Medical School; associate physician, Massachusetts General Hospital.

bronchi Tuberculosis carriers with positive sputum but little x-ray evidence of pulmonary tuberculosis fall into this class

The symptoms of advanced tuberculous bronchitis are wheezing, marked dyspnea, distressing paroxysmal cough, difficulty in raising sputum and fever and malaise caused by retained secretion Increasing cough and expectoration may be the result of bronchiectasis<sup>6</sup> which has developed in the area beyond a partial obstruction

Tuberculosis in the bronchus also plays a part in the formation and persistence of pulmonary cavities Giant or "tennis-ball" cavities<sup>7</sup> are frequently caused by a tuberculous process partially obstructing the bronchus and acting as a ball valve which allows the entry but not the exit of air, and thus produces a "tension" or positive-pressure cavity These cavities may be very difficult to close by artificial pneumothorax or thoracoplasty Even if the cavity is closed, the sputum may remain positive because it comes from the infection in the bronchus itself

When there is complete atelectasis of one lobe or an entire lung without evidence of tuberculosis in the remaining portion of the lungs, x-ray diagnosis is difficult In such cases a mistaken diagnosis of bronchiogenic carcinoma is sometimes made

Bronchial tuberculosis, like tuberculous laryngitis, may heal spontaneously, but if it is extensive enough to be recognized clinically the prognosis is usually unfavorable Emphasis is therefore being placed on the early diagnosis and treatment of this complication So far no satisfactory treatment has been devised but such procedures as the following are being tried deep x-ray therapy, general ultraviolet light treatment, and local treatment through the bronchoscope with silver nitrate, live wire cauter, electrocoagulation,<sup>8</sup> localized ultraviolet light<sup>9</sup> and mechanical dilatation of stenosed bronchi In special cases tuberculomas and glands which have ulcerated into the bronchus have been removed through the bronchoscope

#### LATENT OR ASYMPTOMATIC TUBERCULOSIS

It is now customary to x-ray the lungs of large groups of supposedly well people or of those with indefinite symptoms There are few more difficult problems in medical practice today than the clinical evaluation of such x-ray films Serial x-rays may show progression of a tuberculous process for months or years before symptoms develop There is not even elevation of temperature, so that the old idea that the activity of a tuberculous process can be determined by the thermometer has long since been discarded Some of these latent lesions develop into manifest or fatal disease, others clear without giving symptoms and become the scars

and calcifications so common at autopsy How, then, shall we select the cases needing treatment in the asymptomatic phase?

An unusually clear and practical discussion of this problem was presented by Amberson<sup>10</sup> at the meeting of the Massachusetts Medical Society in June, 1938 "Sound judgment," he said, "depends on a careful correlation of all factors which can be identified and estimated in the individual case" He pointed out the dangers of infection in the adolescent girl, in the Negro race and in people of low social economic status with exhausting occupations He stressed the importance of recency of contact in infancy and during or shortly before adolescence "The intensity of the tuberculin reaction is no indicator of the probable behavior of latent lesions," but "long-standing allergy" as shown by the tuberculin test "is associated with an increasing relative immunity against the tubercle bacillus" Contrary to repeated statements by eminent authorities, he maintained that a first infection beyond the age of childhood should be treated with the same care as a reinfection at these ages Multiple or larger lesions demonstrated by x-ray, he asserted, were of more significance than single or small ones, basal lesions were no more important than apical ones

If we can rely on blood studies to tell us whether or not a given lesion is active, white-cell counts, differential counts and red-cell sedimentation rates should be of particular help in the study of asymptomatic lesions Unfortunately, as Amberson points out, "normal findings do not exclude the possibility that a latent lesion is dangerous or even actively progressive" Nevertheless, abnormal findings in the blood are important and should be considered in the decision as to treatment There is a danger in overemphasizing their significance

#### TUBERCULOSIS IN NURSES AND MEDICAL STUDENTS

Attention is being focused on the number of cases of pulmonary tuberculosis developing in college students, medical students and student nurses<sup>11</sup> The subject was considered of sufficient importance to give it a place on the program of the general assembly of the Congress of American Physicians and Surgeons in Atlantic City in May, 1938, the paper was by Soper and Amberson<sup>12</sup> The percentage of positive tuberculin reactors, they reported, is higher in the East than in the Middle West and in the city than in the country Studies made in eighty-five colleges reveal that on admission from 30 to 50 per cent of the students have positive tuberculin tests and at graduation from 35 to 60 per cent In the medical schools on admission from 60 to 70 per cent of the students have positive tests and at graduation from 85 to

95 per cent In the nursing schools in this country about 60 per cent have positive tests on admission and 90 per cent at the end of a three years' course of training These figures show how quickly medical students and nurses are infected by tubercle bacilli

When routine x-ray examinations are made, 0.6 per cent of the college students show true pulmonary tuberculosis In the medical schools 1.5 per cent of the students give x-ray evidence of pulmonary tuberculosis on admission and an additional 1.5 per cent develop it during the four-year course Only about half of the students in these two groups are treated for active disease Figures for the nursing schools are somewhat higher, especially where tuberculosis wards are connected with hospitals In the United States from 30 to 60 per cent of the student nurses have x-ray evidence of disease, and about half of them require treatment These figures are disturbing but not alarming, for by improvement of the nursing technic the number of students developing x-ray evidence of the infection in one school was reduced from 5.5 to 1.6 per cent

One other interesting problem which is being settled by such studies is that of the immunity conferred by slight degrees of tuberculous infection In the nurses it has been possible to determine whether the individual giving a positive tuberculin test is less likely to develop pulmonary tuberculosis after exposure on the wards than the one who has a negative tuberculin test The figures now obtained in this country support those published a number of years ago by Heimbeck, of Oslo, and there seems little doubt that tuberculous infection sufficient to give a positive tuberculin test affords a certain amount of immunity Heimbeck's figures, quoted by Soper and Amberson,<sup>12</sup> are as follows of 625 student nurses with positive tuberculin tests who nursed patients with active pulmonary disease, 20 developed pulmonary tuberculosis and there were no deaths, of 280 negative reactors, 57 developed pulmonary tuberculosis and there were 10 deaths Heimbeck draws the conclusion that tuberculin allergy is tuberculin immunity

If girls under twenty are to be allowed to nurse tuberculous patients strict precautions must be taken, but to observe the same precautions as in the nursing of scarlet fever patients seems unnecessary All general hospitals admit some patients with pulmonary tuberculosis, usually before the diagnosis is made, and the nurse may be caring for an open case without knowing it For this reason certain hospitals are now requiring a routine chest film on all patients admitted

#### NON-CASEATING TUBERCULOSIS AND SARCOID DISEASE

Strangely enough, three groups of specialists working in different fields have "discovered" a disseminated disease occurring in the lungs and many other organs of the body which is histologically and roentgenographically like tuberculosis but runs a comparatively benign course Tuberculosis specialists have spoken of "cold" tuberculosis, chronic miliary tuberculosis, torpid forms of disseminated tuberculosis and hematogenous non-miliary pulmonary tuberculosis Dermatologists have found that "sarcoid disease" of the skin is histologically like non-caseating tuberculosis and that it is frequently associated with glandular enlargements and cystic bone changes The chest x-rays of these cases often show enlarged hilus glands something like Hodgkin's disease, miliary lesions indistinguishable from miliary tuberculosis or a combination of glandular and parenchymal lesions Ophthalmologists now recognize a form of uveitis<sup>13</sup> clinically resembling tuberculosis of the eye but often associated with parotitis, and accompanied by a negative reaction to strong dilutions of tuberculin rather than the expected positive reaction to very weak dilutions This tuberculin anergy is present in most of the cases of the phthisiologist and also the dermatologist

In the past year Pinner<sup>14-16</sup> has reviewed the extensive literature on these conditions and presents a sound argument that they are all forms of non-caseating tuberculosis He maintains that if the lesions could be studied very early tubercle bacilli would be found, but that because of some peculiarity of the infecting organism or the resistance of the host, the atypical "cold" lesions develop rather than the characteristic lesions of tuberculosis Furthermore, he cites a case of sarcoid disease which after many years of observation changed into true caseous tuberculosis In a series of cases observed by Hunter at the Massachusetts General Hospital, however, both the glandular and miliary lesions disappeared after a few months of general hygienic care

Typical chest x-rays of sarcoid disease may occur with erythema nodosum and rheumatic fever This is of interest because erythema nodosum has been considered a form of tuberculosis Five per cent of the nurses in Heimbeck's series quoted above developed erythema nodosum in the course of their training

From the standpoint of prognosis it is important to realize that there is a group of diseases which may be confused with lymphoma or miliary tuberculosis, possibly representing an atypical form of tuberculous infection, and as a rule benign<sup>17 18</sup>

## STATISTICAL EVALUATION OF COLLAPSE THERAPY

In the last ten years a great change has taken place in the treatment of pulmonary tuberculosis. In the eastern part of this country, at any rate, those well qualified to judge believe that about 70 per cent of the patients in the sanatoriums should be treated by artificial pneumothorax, phrenic nerve paralysis or thoracoplasty. However, statistics to support this strong clinical impression have been difficult to obtain, and we now have the statistician Drolet<sup>10</sup> maintaining that "most of such studies have limited themselves to the immediate results of treatment and are an incorrect or incomplete measure, they should deal rather with the ultimate results." He concludes "Sanatorium or surgical treatment of pulmonary tuberculosis would seem so far to have had little effect upon the case fatality rates of the entire tuberculous population in the communities studied." "Case fatality rate" means the ratio of deaths in a given community to the new cases reported in that community during the same period of time. For example, in Massachusetts in 1915 there were 8046 new cases reported, with 4194 deaths. In 1935 there were 3594 new cases, with 1814 deaths. The case fatality in 1915 was therefore 52 per cent and in 1935 had dropped to only 50 per cent. He goes on to analyze the figures relating to cases discharged from the sanatoriums in the United States, and shows that in 1925 the mortality ratio to the total discharges alive or dead was 20 per cent, while in 1934 it was 24 per cent. He states "It may, therefore, be concluded from the obvious decline of tuberculosis and the comparatively slight change in the case fatality rate that the preventive aspects of isolation in tuberculosis hospitals have been far more effective than those arising from sanatorium or medical treatment." The proportion of all tuberculosis cases which are now isolated in sanatoriums has increased remarkably in the past twenty years. For instance, in the state of New York in 1915 only 8 per cent of the total tuberculosis cases were isolated in hospitals, whereas in 1934 the figure had reached 34 per cent.

Drolet's only conclusion in favor of collapse therapy is that "persons dying from tuberculosis now are slightly older [3 to 5 years] than formerly."

The clinician is somewhat mystified by these indirect conclusions but is forced to reckon with them. Perhaps it is true that collapse therapy in the far-advanced cases which make up so large a percentage of the sanatorium population will prolong life but not greatly influence the mortality rate. In that case greater emphasis should be placed on early diagnosis and treatment, and we

are again faced with the problem of the asymptomatic lesion. In any event, no physician who has followed carefully a large group of cases treated with collapse therapy will be willing to give up the procedure because of Drolet's figures.

## EXTRAPLEURAL PNEUMOTHORAX

New methods of collapse therapy and changes in the technic of the older methods are constantly being introduced. During the past year attention has been drawn to extrapleural pneumothorax.<sup>11-13</sup> In many cases it is impossible to establish a satisfactory intrapleural pneumothorax because the visceral and parietal pleurae are adherent. In some of these cases the surgeon can remove a section of a rib and strip the parietal pleura from the chest wall, allowing the collapse of the underlying lung. This collapse can then be maintained by injections of air between the chest wall and the parietal pleura using the method employed to inject air between the visceral and parietal pleurae in intrapleural pneumothorax. If the patient's condition allows thoracoplasty most surgeons prefer it, if not, extrapleural pneumothorax can be established with a minimum of shock. This treatment may be sufficient in itself or may improve the patient's condition so that thoracoplasty can be performed later.

The possible complications of extrapleural pneumothorax are tuberculous infection in the extrapleural space, and rupture of a large tuberculous cavity into it as a result of the separation of the lung from the chest wall. As in all collapse treatment, there must be a rigid selection of cases, and the surgeon should not be pushed into operation "just because there is nothing else to do."

## VITAMIN THERAPY IN PULMONARY TUBERCULOSIS

Many years before the present vitamin craze, cod-liver oil proved its value in the treatment of tuberculosis, and in recent years vitamins D and C have been used extensively in the treatment of intestinal tuberculosis. Many people think that it is the vitamin and not the accompanying ultraviolet light treatment which is responsible for the improvement in these cases. In recent studies of vitamin C it has been found that tuberculous patients have a very low urinary excretion of this substance. As a result, many institutions have given their patients concentrated vitamin C. No conclusive articles have appeared to date, but there seems little doubt that in an appreciable number of cases it does increase the appetite and therefore helps in the essential upbuilding process.

## SULFANILAMIDE IN EXPERIMENTAL TUBERCULOSIS

At a time when sulfanilamide is being used so extensively in the treatment of various bacterial

infections it is right that its effect should be tested in the laboratory on the growth of tubercle bacilli in the test tube and in animals. Experiments to date indicate that in certain concentrations sulfanilamide does exert an inhibitory effect upon such growth.<sup>23-25</sup> There are as yet no reports on the use of the drug in tuberculosis in human subjects.

Sulfapyridine, too, is being subjected to the same laboratory test and experiments are under way to produce a form of sulfapyridine which can penetrate the fatty capsule of the tubercle bacillus. Needless to say, the time has not yet come to use these drugs on cases of tuberculosis occurring in general practice.

## CASE 25231

### PRESENTATION OF CASE

A fifty-year-old female Negro nurse was admitted complaining of fever, generalized aching and sore throat of three weeks' duration.

For the past fifteen years the patient had had occasional attacks of very severe pain in the right upper quadrant, sudden in onset, requiring opiates for relief and associated with nausea and vomiting. They lasted about two days and were followed by tenderness and weakness. There was no jaundice. They recurred about every six months, the last being one year before entry. For the past seven years she had had aching and stiffness in various joints, often localized in the hands and occurring in wet weather. Three years before admission she was admitted to an outside hospital for "double pneumonia" and acute rheumatic fever, remaining there for three months. Following this she had frequent dry cough throughout the winter. Three weeks before entry she was awakened with a severe shaking chill and definite malaise. The chill lasted about ten minutes and the temperature rose to 104°F. She had slight headache. Her physician stated that she was ill with a "bad heart" and gave her digitalis. There was generalized aching, a sore throat and sore mouth. Her temperature remained at 101 to 103°F for three days then fell to under 99.5°F for ten days. After the acute illness she complained of great weakness though her appetite was excellent. Eight days prior to admission her temperature rose to 100°F and she complained of gas in her abdomen. There was distention relieved by heat and an enema. She began having two or three bowel movements daily, with well-formed brown stools. She also noted pain under both shoulders and severe pain across the upper anterior chest which was not increased by respiration. Associated with this was rapid heart action. At about the same time drowsiness developed and on one occasion she complained of numbness throughout the right side of the body, except the face, which lasted for only a few hours. There was no paralysis, and complete recovery ensued. A severe dry cough developed. Back pains were noted and slight tenderness in the right wrist. Two days later

anorexia developed accompanied by frequent gas pains. An enema gave good results and relief. Two days before entry her temperature was 102°F and her sore throat seemed to be returning. On the following day her abdominal distention was again relieved by heat and an enema. Her physician found a negative abdomen, the chest clear, but a temperature of 101°F. She had had no urinary symptoms and her urine had been light colored. There had been no jaundice. She had had two children and one miscarriage.

Physical examination showed an obese, perspiring, restless woman obviously ill and in a semistuporous condition. There were frequent attacks of dry, brassy coughing. Examination of the fundi oculi was negative. The tongue was red in the center, the sides were coated. The anterior tonsillar pillars showed a dusky redness covered with dry, white, glairy mucus. The chest was clear. Frequent squeaks were heard over the trachea. The heart rate was 100, the rhythm was regular. The heart was somewhat enlarged to the left. There was a soft systolic murmur at the apex. The blood pressure was 186 systolic, 98 diastolic. The abdomen was obese and soft, with diffuse tenderness in the epigastrium. Pelvic examination was negative. There was no edema. The reflexes were equal and normally active.

The temperature was 103°F rectally, the pulse 115, and the respirations 40.

Examination of the urine showed a specific gravity of 1.028 and was negative except for the presence of 5 white cells per high-power field. A urine culture showed no growth. The blood showed a red-cell count of 4,560,000 with 64 per cent hemoglobin, a white-cell count of 25,900 with 89 per cent polymorphonuclears, no abnormal cells in the blood smear. Agglutination tests for typhoid, paratyphoid and undulant fever were negative. A van den Bergh was normal, indirect. Two blood cultures showed no growth. A throat culture showed a moderate growth of beta-hemolytic streptococcus. A lumbar puncture showed an initial pressure of 180 mm. There were no cells. The total protein was 17 mg per 100 cc, sugar 169 mg, and the goldsol curve 0100000000. A spinal-fluid Wassermann test was weakly positive. An electrocardiogram showed a rate of 110 with normal rhythm. The P-R interval was 0.18 second, QRS duration 0.12 second. T<sub>3</sub> was inverted, QRS 1, 2, 3 and 4 notched.

On the third hospital day physical examination was essentially unchanged. There were questionable rales at both bases, but examination was difficult because of a large obese chest wall. There was no stiff neck. Reflexes were hypoactive. Neurological examination was otherwise negative.

On the following day she was mentally dull and still acutely ill. She complained of joint pain and pain across her upper abdomen. There was limitation of motion of the right wrist with pain, and some pain on moving the right elbow. The abdomen was greatly distended in the upper half and rigid over the left upper quadrant. Palpation in the upper abdomen apparently caused pain. No peristalsis was audible in this region. A surgical consultant found that the upper abdomen was extremely tender especially in the left upper quadrant. Spasm could not be determined because of obesity. Peristalsis was normal. She had not vomited. Examination of the urine at this time revealed a trace of bile. Her white-blood-cell count ranged between 15,000 and 27,000. An x-ray film of the chest revealed no evidence of pulmonary disease. On the following day a gastric aspiration showed 400 cc of recently ingested fluid which was guaiac negative. The stool was brown, liquid, a guaiac test was negative.

The abdomen was tapped in three different places and nothing was found. On the sixth hospital day rales were heard at both bases. A chest film showed some consolidation in the medial portion of the left lung. Her temperature, pulse and respirations had remained essentially the same since entry. She rapidly failed and died on the eighth hospital day.

#### DIFFERENTIAL DIAGNOSIS

DR. ALVAH H. GORDON \* When I was given the opportunity of speaking here, I said, "Timeo Danaos et dona ferentes," and now I have much sympathy with Daniel when he was introduced into the lion's den. I am not familiar with the rules of this game, but I believe all the pertinent information is on this sheet. If it is, I am afraid I am in trouble.

On reading this story, one is impressed by the first few words, "A fifty-year-old female Negro nurse complaining of fever, generalized aching and sore throat of three weeks' duration." Of course that would immediately suggest an agranulocytosis, but as one looks farther down he realizes that there is nothing in that, because the white-cell count is 25,900 with 89 per cent polymorphonuclears. The next thing we come across is the statement that for fifteen years she had had severe pains, in the right upper quadrant of the abdomen, of sudden onset and occurring frequently. The obvious inference is that an obese woman has suffered from attacks of cholelithiasis, which is a reasonable supposition. Then having taken that for granted, if we may do so for a few moments, we

pass on and go through the story and find the development of sore throat from an acute infection with the *Streptococcus hemolyticus* which any of us might develop whether we had acute cholecystitis or not. Then later on she developed a pain in the upper abdomen of a quite acute type, and in one instance it is stated that there was some spasm in the left upper quadrant. The acute pain in the upper abdomen and the tender areas both suggest the possibility of pancreatitis which had developed on the basis of previous cholecystitis. There are two or three things which are against that, however. There is one which directly suggests it. The cerebrospinal fluid sugar was 169 mg per 100 cc. which would indicate that possibly the blood sugar may also have been elevated even though there was no sugar in the urine. We have no figures for the blood sugar so we have to infer without having actual knowledge. However, there are two strong points against the diagnosis of acute pancreatitis. One is that there was no vomiting, and so far as my own experience goes, acute pancreatitis without vomiting must be a very rare occurrence. Another interesting point is that a surgeon saw her and apparently nothing was done. That is considered significant. So, while it is all very true that an acute pancreatitis might very reasonably give rise to her abdominal symptoms, there are some things which it does not account for. It does not account for the fact that she had pain over the upper portion of the chest, and while her temperature and pulse were of moderate range her respirations were definitely elevated beyond the rate which would be suggested by the elevation of the temperature and pulse. Just here one must interrupt oneself and speak again of the disease which when it is diagnosed is rarely present, and when present is rarely diagnosed, that is periarteritis nodosa. There is no doubt that this story throughout might quite readily be present with periarteritis nodosa. One of the very few cases which I have seen came on with an extreme sore throat, such as this patient had, and at the same time with many signs in the chest indicating the presence of pneumonia, and without any suspicion of the disease (periarteritis nodosa) until it was found postmortem.

To come back to the thing that offers the most likely explanation there is scattered from place to place throughout the story, evidence that this woman had had acute rheumatism, and at various times, pains here and there in certain joints. They are specifically stated as being present in joints. She had fever. Then she developed a sore throat, with the finding of a hemolytic streptococcus. That, too, is a pretty common occurrence in the presence of rheumatic fever or rheumatic infec-

\* Professor of medicine, McGill University Montreal, Canada physician, Montreal General Hospital.

tion More than that, with the onset of acute infection, the acute manifestations of rheumatic disease may appear Among these is acute pericarditis We find the statement that her heart was somewhat enlarged to the left, to say nothing about the right No mention is made as to whether she had or had not a pericardial friction I think it would be unwise to mention that even if it were present

DR. TRACY B MALLORY We would not hold anything like that back Everything is here, sir

DR. GORDON But I am still more like Daniel in the lion's den To me, looking at it from that standpoint of the most likely explanation of the story, the upper abdominal pain is quite compatible with acute pericarditis, as are also the pain across the front of the chest and the rapid respirations, and the background of rheumatic infection and infection of the throat, and the development of the terminal symptoms which she showed There is one point that is difficult to explain under the present circumstances, that is the high cerebrospinal fluid sugar There is no evidence that she had any of the intracranial causes for such elevation

Perhaps I might see the x-ray films of the chest

DR. A THORNTON SCOTT Is that correct about the cerebrospinal sugar? I do not remember anything about its being elevated

DR. MALLORY It is down as that in the record

DR. GEORGE W HOLMES Unfortunately these are portable films and do not give so much information as they should She has a very high diaphragm with obesity The lungs are less clear than I would expect them to be in an ordinary film The films were taken with the patient lying on her back at a rather close distance and the apparent, wide heart shadow is not so reliable a finding as in films taken the regular way The first films were taken on the twenty-eighth, and this one on the thirty-first, three days later The last film is so distorted that we will have to discard it as being of very little value I do not see anything in the lung field that I would interpret as being abnormal The heart shadow is certainly somewhat increased in size in these films, but we have to take into consideration the things that I have already mentioned and discount that considerably However, I think it would be fair to say there is enlargement of the heart shadow The various chambers of the heart can be made out and there is only moderate increase in the supracardiac shadow That would be against an accumulation of fluid in the pericardium A small amount, 300 cc, might be present in such a case without showing any more distortion of the heart shadow than

this does Certainly there is no large amount of fluid and no evidence of fluid in the pleural spaces

DR. GORDON My final conclusion is that the probability in this case lies with acute hemolytic streptococcal infection and the development of rheumatic plastic pericarditis My own belief is that there was also a small amount of fluid present in the pericardial sac The other suggestions that I have mentioned in the beginning I believe were probably not correct (agranulocytosis, periarthritis nodosa, acute pancreatitis)

DR. JOHN H TALBOTT I admire Dr. Gordon's discussion Each morning on the visit we would go over the list of diagnostic possibilities and discard them one by one The last note on the record is the one that best expressed our sentiments This stated that we had no idea what the patient died of

#### CLINICAL DIAGNOSES

Pancreatitis?  
Perforated peptic ulcer?  
Bronchopneumonia

#### DR. GORDON'S DIAGNOSIS

Acute rheumatic pericarditis

#### ANATOMICAL DIAGNOSES

Acute rheumatic pericarditis  
Rheumatic myocarditis  
Chronic cholecystitis and cholelithiasis  
Pulmonary congestion and edema  
Obesity  
Cortical adenoma of the adrenal

#### PATHOLOGICAL DISCUSSION

DR. MALLORY The only clinical diagnosis we found listed on the autopsy permission sheet was obesity At postmortem examination the peritoneal cavity was absolutely negative except for a few areas of petechial hemorrhage low in the pelvis which I think were probably on a circulatory basis and insignificant The pericardium, in contrast, contained about 175 cc of turbid fluid, conclusive evidence of acute pericarditis The heart was considerably hypertrophied, weighing about 420 gm All the valves were absolutely negative The coronaries showed minimal atheroma with no significant narrowing The myocardium was a little abnormal in gross appearance, enough so that a frozen section was done at the time of autopsy That has since been confirmed with many other sections and I have seen only one other heart that contained as many Aschoff's nodules as this one That other instance, incidentally, also occurred in an individual

over fifty years of age but one who had had little or no previous evidence of acute rheumatic fever. There were a few stones in the gall bladder which I think account satisfactorily for the repeated episodes of pain in the right upper quadrant. A cortical adenoma of the adrenal about a centimeter in diameter was also found but apparently played no role in the symptomatology.

## CASE 25232

### PRESENTATION OF CASE

A seventy-three-year-old white woman was admitted complaining of pains across the upper abdomen of two weeks' duration.

For the past six months she had not been entirely well but had no definite symptoms. Three and a half weeks before admission she was thrown forward in a street car, suffered a twist and was somewhat dazed. She remained in bed for the next week. Two weeks before entry she noted the onset of upper abdominal pain located along an arc the center of which lay about 5 cm. above the umbilicus, the ends lying 10 cm. to each side of the umbilicus. The pains radiated from left to right and caused nausea and vomiting. She vomited practically everything she ate during the last two weeks. The pain did not awaken her at night and did not cause her to cry out but at times did cause her to double up. With the onset of the pain two weeks before entry she noted the appearance of a yellow tint to her skin. Both her urine and stools became very dark. She had not had numbness or tingling of the extremities. During the last six months she had lived by herself and had done her own cooking. Her appetite had been increasingly poor for nearly a year. She ate some meat about five times a week but only few vegetables and little fruit. She had lost some weight.

Physical examination showed a well-developed and nourished woman who was slightly but definitely jaundiced. The tongue was atrophic. There were no other definite physical findings. Pelvic and rectal examinations were negative. The blood pressure was 120 systolic, 70 diastolic.

The temperature was 99.2°F, pulse 70, respirations 20.

Examination of the urine was negative. The blood showed a red-cell count of 2,070,000 with 50 per cent hemoglobin and a white-cell count of 11,500 with 75 per cent polymorphonuclears. There was no achromia, but there was moderately marked variation in size of the red cells, some larger than normal. No oval cells were seen. There was considerable polychromatophilia and suppling in

the large cells, but no nucleated red cells were seen. The platelets were normal. A reticulocyte count was 14.9 per cent. The hematocrit was 24, cell volume 93. The icteric index was 25. A blood Hinton test was negative. Stools were of normal color and the guaiac test was negative.

X-ray films of the chest showed the right diaphragm to be unusually high in position. It was smooth in outline and suggested enlargement of the liver. There was an irregular density occupying the right cardiophrenic angle and there was also hazy density along the lung markings extending to the left base. The upper lung fields were clear. The heart shadow was a little prominent in the region of the left ventricle. The aorta was tortuous and there was calcification in the arch. A lateral view of the skull showed irregular thickening of the frontal bone due to frontal hyperostosis. A gastrointestinal series showed a normal gastrointestinal tract except for a small hiatus hernia. The Graham test was negative.

On the third hospital day the liver was found to be palpable 3 cm. below the right costal margin. The spleen was definitely palpable. Liver extract was given intramuscularly on the third, fourth, fifth, eighth, tenth, eleventh, twelfth and thirteenth days. On the fourth, fifth, sixth, seventh and eighth hospital days the reticulocyte counts were 11.5 per cent, 11 per cent, 13.9 per cent, 13.6 per cent and 14.2 per cent respectively. On the ninth hospital day the red-cell count was 2,590,000, hemoglobin (photometric) 80 gm., white-cell count 7600. No nucleated red cells were seen. A fragility test showed hemolysis beginning at 0.42 per cent saline and was not complete at 0.24 per cent saline. A control showed hemolysis beginning at 0.42 per cent, complete at 0.28 per cent. Tests for urobilin and urobilinogen in the urine were positive and the foam test bile was positive. Stool examinations continued to show normal color and a negative guaiac test. On the thirteenth hospital day the reticulocyte count was 15.4 per cent and four days later 22.7 per cent. The patient slept most of the time. Edema of the feet had developed. On the fifteenth and sixteenth hospital days she was disoriented. There was definitely less motion in the left cheek and mouth. Rales appeared at both lung bases. On the eighteenth hospital day her pulse became weaker. Asthenia increased. Shortly after midnight she became cold, dyspneic, had air hunger, became comatose and died.

### DIFFERENTIAL DIAGNOSIS

DR. F. T. HUNTER. I should like to make some comments on this history. To begin with, her appetite had been poor for nearly a year, she had

not been entirely well and for six months she had been doing her own cooking. We cannot judge about the cooking. It possibly was so poor that her appetite decreased, yet I think there is more behind her lack of appetite than her gastronomic endeavors in the kitchen.

We are not informed whether the ankle, the abdomen or the neck was injured. We shall have to leave that question aside for the moment. She was dazed. I think most people are when a car stops suddenly, or when they get hit,—particularly women.

She stayed in bed the next week. I am interested to know why. Was it because of the shock or pain, although the pain was not supposed to have come on until later? Did her doctor advise her to stay in bed, or did her lawyer? If it was her lawyer I presume we can neglect this whole accident as a cause of her subsequent illness.

Nothing is said about the character of the pain. We are told it was definitely localized in the upper abdomen and did not wake her at night. I should imagine it was colicky pain. It certainly was related somewhat to position, because when she was lying in bed at night it was better, or at least it did not bother her. Vomiting, however, continued. I should like to know whether she had medication. Did her doctor give her morphine? Old people will sometimes vomit after morphine or at least have nausea. At about this time it was noticed that she had a yellow tint to the skin. We would like to know whether it had been present before, or whether her doctor called her attention to it, that is, if she had a doctor.

The dark stools are apparently not due to blood because later on the guaiac test was negative. When in the hospital pernicious anemia was suspected because mention is definitely made that she had no numbness or tingling.

She probably had an inadequate diet. She had lost weight, but we do not know how much. Ordinarily, people are vague about loss of weight, if they lose twenty pounds or more they notice it, but "some" weight loss usually means five or six, possibly ten pounds. Her loss of weight may be due to the fact that she had not eaten much for a couple of weeks.

Physical examination states that she was well developed and nourished. If she had carcinoma in the abdomen involving the liver or bile ducts I do not believe that she would have shown good nourishment at the time of examination. Furthermore, I think she probably would have had a longer story of pain. The jaundice was definite. The tongue was atrophic. We have no knowledge as to whether or not it had ever been sore—pre-

sumably not. So in the physical examination we find a well-nourished woman with jaundice and an atrophic tongue and we think right away of pernicious anemia. The slight increase in temperature would go perfectly well with that diagnosis, but the temperature could also go with carcinomatosis.

"Examination of the urine was negative." If this is correct she certainly did not have obstructive jaundice because if you can see jaundice in the skin you are certainly going to have bile in the urine even by the crude test of shaking a test tube of urine.

So far we are thinking of pernicious anemia. The first thing that seems odd is that the white count is high and the polymorphonuclear count unusually high for this disease. There is no mention as to whether myelocytes were seen in the blood smear or whether the polymorphonuclears showed multiple lobulation such as you see in pernicious anemia. The variation in size of the red cells goes with any type of anemia of this severity. The next point of interest is that there were no nucleated red cells found. They were thinking of cancer metastases in the bone marrow. The reticulocytes were 15 per cent. The first thing that comes to mind is hemolytic jaundice. I have seen a blood smear of a child with this disease with 87 per cent reticulocytes. The cell volume was higher than normal. If the cell volume is based on the recorded two million count, according to my figures it should be 116, but I presume there was another count done on the venous blood which brought that figure down to 93. It would be helpful to know whether the van den Bergh was diphasic or indirect. The stool was normal in color, with no blood. We would like to know whether she had been given any liver extract either by mouth or by injection by the doctor who took care of her before she came in, that is if she had a doctor. The icteric index of 25 is high. I should think for pernicious anemia with a red count of two million.

We have no definite information in regard to the date of this x-ray film of the chest, whether it was made just before death, or on entry to the hospital. I should like to know why the skull plate was taken. Were they looking for metastases, Paget's disease, or were they still looking for something resulting from the streetcar ride? If the gastrointestinal series is normal I should like to be sure that there is no displacement of the duodenum by tumor in the region of the pancreas. The Graham test was negative, and therefore I think the van den Bergh test would have been indirect if it had been done, because with a diphasic van den Bergh, the Graham test is

usually positive, that is, the gall bladder fails to fill, or fills only faintly. May we see the x-ray films?

DR. GEORGE W. HOLMES: The record states that the diaphragm was high on the right. I think it is, but I would not be at all certain that it was due to a large liver. It may be. In the other films where the liver is particularly well seen it does not seem to be enlarged. I do not see the spleen. She has something in her lung in the angle between the diaphragm and the heart which could be a destructive process or collapse. That may account for the high position of the diaphragm. These films were probably taken at full inspiration and anything that would cause her to fix her diaphragm on that side would also account for the high position. I think the films actually offer less information than one would assume from reading the record. The gall bladder is rather faint but is about normal in size and contracts after food, and I think we have to interpret it as negative. This film of the skull shows exostoses in the frontal region which so far as I know are of no importance.

DR. HUNTER: What about the date of the chest film?

DR. TRACY B. MALLORY: The chest plate was taken on the tenth day.

DR. HUNTER: She died on the eighteenth. It seems that we derive no further information from the x-ray examinations. The important information we do obtain about this patient comes from her course in the hospital. The liver was palpable 3 cm. below the costal margin. I assume that was found after the x-ray report was turned in. The spleen was said to be palpable on the third day and that corresponds to the time when the visiting man probably felt it. Liver extract was given. The first question we want to bring up is whether or not she was given potent material, because if a potent extract is given we do not usually see pernicious anemia developing a reticulocyte count so high as this and having it remain constant. On the ninth hospital day the red-cell count had apparently increased by a half a million, the white-cell count had fallen somewhat, and they kept looking for nucleated red cells.

DR. MALLORY: A potent extract was given from the start.

DR. HUNTER: In pernicious anemia the spleen is enlarged and palpable in a small percentage of cases, perhaps 15 or 20 per cent. Nowadays we are apt to find very few enlarged spleens because patients are diagnosed and treated before they have the anemia long. The fact that there were no nucleated red cells is against this being metastatic tumor in the bone marrow. In relation

to a diagnosis of hemolytic jaundice, the fragility was normal. Moreover, I should be amazed to find a woman of seventy-three with congenital jaundice manifesting itself for the first time at her age. I do not believe the foam test on the urine was positive, because urates often give a yellowish red color to the foam.

Suddenly, on the seventeenth day, the reticulocytes jumped to 22.7 per cent. We want to know whether this was a delayed response, or a terminal attempt of a pernicious anemia marrow to turn out red cells. In regard to the tendency to sleep we should have to inquire into the medication given. The edema of the feet was probably mild cardiac failure plus anemia in a woman of seventy-three.

She became drowsy, and there was definite evidence of something happening in the right cerebral hemisphere because of the evidence of paralysis on the left side of the face. The rales heard could have been due to cardiac decompensation, or to a hypostatic pneumonia. The rest of the story tells nothing except that she finally died.

When we go back over this whole story there are several things that make us consider this a case of pernicious anemia which has failed to respond to treatment. The possibility of hemolytic jaundice I am going to discount right away because of her age and the lack of other evidence. I am going to say definitely that I do not think the streetcar accident had anything to do with her death because she had a normal abdomen, and I do not believe that had there been an injury to a viscus she would have had a perfectly normal abdomen. To account for the pain, she might perfectly well have injured her spine, otherwise I cannot account for it.

I am going to make a diagnosis of pernicious anemia which failed to respond, and, possibly, cerebral thrombosis. She probably had a terminal pneumonia and, perhaps, mild congestive failure. Whether or not a spinal injury will be found, I do not know. Those are the diagnoses that I have to stand by, but I feel like the musician playing a Debussy quartette, who said after he got through that he knew every note was wrong, but he did not dare change it because he might be right.

DR. MILTON H. CLIFFORD: The story this woman gave when she came in was just as troublesome as Dr. Hunter has found it. I believe it was her lawyer who told her to go to bed for the first week. She had had very little medical attention. Her family had known that she was not in good health but nothing came to a head until this accident, the details of which could not be obtained any more satisfactorily than has been recorded here. She was fairly well nourished. She had had no liver therapy before entry so far as

we know. On entry probably the reason the liver was not felt is that she held herself quite rigid and had some distention at the time. The results of abdominal examination varied, although the liver could be felt and a mass in the left upper quadrant could be made out which I presumed to be spleen. She continued to be drowsy the whole of her course and did not respond to liver therapy.

DR. WYMAN RICHARDSON: I think it is fair for me to say that I was more impressed by the upper abdomen than the examiner who is quoted in the record and I was not so certain that it was spleen we felt. The other thing I should like to say is that I am much interested in the picture like this that simulates hemolytic anemia. I have seen it in another case of the same type and the remembrance of that case led me to make a fairly good guess in regard to this one. I think it probably will not be a hemolytic anemia, but there may be another cause for the jaundice and the reaction of the bone marrow may be the reaction to this disease that Dr. Mallory is going to tell us about.

DR. MALLORY: You did not think that the spleen was palpable?

DR. RICHARDSON: I did not, but Dr. Clifford thought that it was.

DR. HUNTER: Where am I left then?

#### CLINICAL DIAGNOSIS

Carcinomatosis

#### DR. HUNTER'S DIAGNOSES

Pernicious anemia  
Bronchopneumonia (terminal)  
Cerebral thrombosis?  
Congestive failure (mild)?

#### ANATOMICAL DIAGNOSES

Carcinoma of the pancreas with metastases to the liver  
Pernicious anemia  
Bacterial endocarditis, acute terminal, mitral and aortic  
Jaundice, slight

#### PATHOLOGICAL DISCUSSION

DR. MALLORY: The autopsy on this patient showed a carcinoma of the body and tail of the pancreas which had grown around the splenic artery and vein and practically occluded them. The spleen weighed only 100 grams so I feel quite sure it was not felt and the mass must have been pancreas. The liver was two-thirds or three-fourths replaced by carcinoma although it was only moderately enlarged. We rather thought at the end of the autopsy that we had satisfactorily explained

the case and we assumed that the anemia without much question was due to widespread metastases to the bone marrow and could be classed as myelophthisic anemia. When the sections came through we found that this was not the case. There were numerous sections of bone marrow without the slightest evidence of metastases and the bone marrow was entirely consistent with pernicious anemia. It shows a marked red-cell hyperplasia with considerable numbers of megaloblasts. Ordinary types of anemia almost never show megaloblasts in significant numbers, and in this hospital in adults we have seen such large numbers of megaloblasts only in pernicious anemia and two cases of benzol poisoning. So I am inclined to believe that she did have pernicious anemia. Possibly she had the very similar macrocytic anemia that is occasionally seen in liver insufficiency. I cannot rule that out. She had one other complication which I think unquestionably had a good deal to do with the exitus, that was a terminal bacterial endocarditis. She had no examination of the head, but I imagine that was embolism from bacterial endocarditis.

DR. HOLMES: Was there any gross change in the shape of the liver?

DR. MALLORY: No.

DR. HOLMES: Anything in the lungs?

DR. MALLORY: There was atelectasis in the right lower lobe and also several small metastatic nodules.

DR. BERNARD M. JACOBSON: There are in the literature several cases of pernicious anemia with diffuse pancreatic disease, usually chronic pancreatitis with fibrosis.

DR. MALLORY: In this case the head of the pancreas was quite normal, but the body and tail were entirely replaced by carcinoma.

DR. RICHARDSON: I wonder if it is fair to call this pernicious anemia on the basis of the finding of a few megaloblasts in the bone marrow. I have an idea that what we often refer to as a myelophthisic anemia is not in fact due to actual crowding of the bone marrow by tumor cells. We have seen patients with widespread malignant disease who showed a leukemoid picture and it is, of course, common to get an anemia with much evidence of marrow activity as shown by the presence of nucleated red blood cells in all stages of maturity. In this case I wonder whether there may not have been malignant disease in some parts of the marrow not examined pathologically which brought about such a regenerative blood picture, and if the jaundice in this case might not have been due to the extensive malignant involvement of the liver. Such a picture superficially resembles a hemolytic anemia.

DR. MALLORY I must confess to almost complete ignorance of the bone-marrow picture in patients with macrocytic anemia dependent on hepatic insufficiency I have made no personal study of it and I have seen few reports in the literature Wintrobe and Shumacker\* mention the bone marrow in two cases which came to autopsy in one it was reported merely as moderately hyperplastic, in the other as normal I have, therefore, assumed it would not be readily confusable with that of pernicious anemia, but my evidence is scant

As regards myelophthisic anemia we have felt that the major part of the bone marrow must be

diffusely replaced by tumor before it develops and therefore one could hardly miss it at autopsy if three or more flat bones were sampled Moreover, such cases when the anemia is severe almost always show extramedullary hematopoiesis in the liver and the spleen as a further check upon one's diagnosis In fact we have raised the hypothesis that this extramedullary red cell formation might well be responsible for one of the most important clinical indications of myelophthisic anemia in the presence of nucleated red cells in the blood smear even without profound anemia It is easy to imagine that nucleated cells could slip more easily out of the sinusoids of soft and mobile organs like the liver and the spleen than from sinususes of the bone marrow with their bony encasement

Wintrobe, M M and Shumacker H S Jr The occurrence of macrocytic anemia in association with disorder of the liver together with consideration of relation of this anemia to pernicious anemia Bull Johns Hopkins Hosp 32:387-40 1933

## SEVENTIETH ANNIVERSARY OF THE CHILDREN'S HOSPITAL

ON June 8, 9, and 10, the Children's Hospital is celebrating the seventieth anniversary of its founding and the fiftieth anniversary of its nurses' training school. Graduates of the hospital have returned from all parts of the United States. The scientific program, which may be found in detail on another page of this issue of the *Journal*, is being presented by representative graduates of the departments of medicine, surgery, orthopedic surgery and pathology. A scientific exhibit by the present members of the hospital staff is now on view at the hospital.

The Children's Hospital was founded in 1869 by a group headed by Dr. Francis Henry Brown, who had determined "to supply a want in our community which has been felt in our medical schools,

namely, an opportunity to study infantile diseases. These, as every mother and every nurse knows, are so sudden, so fluctuant, and so mysterious, and often so rapid in their fatality, that they furnish a distinct branch of medical science, the importance of which can hardly be overestimated." The first home of the hospital was a small house on Rutland Street equipped for the care and study of twenty patients. Shortage of space forced the hospital to transfer its quarters to a rented house on Washington Street the following year. In 1882 the Huntington Avenue building of the Children's Hospital was built, and in its first year two hundred and eighty ward patients were cared for, and one thousand four hundred and eighty-eight outpatients. Steadily increasing demands forced the transfer of the hospital in 1914 to its present location adjacent to the Harvard Medical School. The new hospital was finally brought into its present form between 1929 and 1931 with the addition of new quarters for neurology, contagious disease and pathology, and improved quarters for patients suffering from surgical diseases of infancy. This last building program permitted the hospital to realize its greatest ambition of being in every sense of the word a *general hospital for children*. Last year the hospital cared for approximately seventy thousand children, over five thousand of these on its wards, the budget exceeded half a million dollars. With beds for two hundred and eighty-three ward patients, a private ward, a staff of about one hundred and fifty doctors, well-equipped laboratories for routine and research work, a nurses' training school, facilities for the teaching of students and the training of young doctors, and a close affiliation with its sister institution, the Infants' Hospital, the hospital today is successfully carrying out the original aims so wisely set forth by the managers in 1869.

The medical and surgical treatment of the diseases of children.

The attainment and diffusion of knowledge regarding the diseases incident to childhood.

The training of young women in the duties of nurses.

The nurses' training school is widely known. Its graduates hold many teaching and administrative

positions. Most of the teaching of pediatrics at the Harvard Medical School is carried on at the Children's Hospital. The interns and resident physicians of the hospital have come from and gone to all parts of this country and many foreign countries. The contributions of the staff of the hospital to medical literature are read throughout the world.

Thus the Children's Hospital not only provides good medical care for the sick of today but also contributes to the provision of better medical care for the sick of tomorrow.

### ACTA MEDICA URSS

Physicians and medical libraries in the United States will welcome the new international journal of medicine, founded by the young commissar of public health, Nicolai Ivanovitch Propper-Grachtchenkoff,\* entitled *Acta medica URSS*. The first two numbers have already appeared, and the papers form a noteworthy collection dealing with many spheres of medical thought and embracing both experimental and clinical medicine.

The new public-health commissar was head of the department of sensory physiology in the All-Union Institute of Experimental Medicine at Moscow before he assumed the heavy duties of directing the public health of the Soviet Union. Dr. Propper is well known in this country since his sojourn as fellow of the Institute of Experimental Medicine, Moscow, in 1936-37, when he carried out studies at the Rockefeller Institute for Medical Research in New York City and at the Laboratory of Physiology at Yale University. The first paper of the first number of *Acta medica URSS* is by Dr. Propper and deals with the role of medical science in the practice of public health, the paper displays a wide knowledge of world medicine, which is rare among Soviet writers. He states that one of the objects of this new journal is to make physicians of the Soviet Union cognizant

of progress in world medicine and that he hopes it will also promote a free interchange of ideas between the physicians of Russia and those in other countries of the world. There is no trace of chauvinism in Dr. Propper's writing and one trusts that the new journal which he and Dr. M. Serejski, the editor, have launched will have the enthusiastic reception which it so richly deserves both in their own country and abroad.

In the prefatory note it is stated that the editorial offices will receive papers in four international languages, Russian, French, English and German. The journal accepts original contributions, and it also reprints papers of importance culled from medical journals elsewhere in the world.

It may interest readers of the *Journal* to learn that the new public-health commissar is doing much to arouse interest in the history of medicine in Soviet Russia. He has already issued a Russian translation of Harvey's *De Motu Cordis* (1628), Galvani's *De Viribus et Electricitatis in Motu Musculari* (1791) and Trembley's celebrated monograph on the Hydra (1744). Other important reprints and facsimiles will be issued by the Commissariat of Public Health at Moscow in the near future. Russian editions of our great medical classics give interest and zest to bibliographers and collectors in the field of medical history, and we hope that Dr. Propper may long continue to promote in his own country the finer cultural and scientific traditions of the art.

City Hospital and was on the staffs of the Charlesgate Hospital, the Phillips House and many other Boston hospitals. At the time of his death Dr Thorndike was clinical professor of genitourinary surgery, emeritus, at Harvard Medical School.

Dr Thorndike was a member of the Massachusetts Medical Society, the American Medical Association, the American Association of Genito-Urinary Surgeons, and the Boston Surgical Club.

A son, Dr William T S Thorndike, and two daughters survive him.

**TIBBETTS**—GUY D. TIBBETTS, M.D., of Antrim, New Hampshire, died June 2. He was in his fifty-second year.

Born in Gloucester he attended schools there and received his degree from Tufts College Medical School in 1911. He served his internship at the Boston City, the Boston State and the Cambridge City hospitals, and then started private practice in Bennington, New Hampshire. Dr Tibbetts was one of one thousand American doctors loaned to the British Government during the World War, and was awarded the Distinguished Service Cross by King George V.

He was a former member of the Massachusetts Medical Society, resigning in 1921 to join the New Hampshire Medical Society, and was also a fellow of the American Medical Association.

His widow survives him.

## MISCELLANY

### MANHATTAN CONVALESCENT SERUM LABORATORY

The New York Department of Health announces that that Manhattan Convalescent Serum Laboratory, a non-profit organization, is prepared to supply measles convalescent serum to hospitals and physicians at the cost of production. The serum is furnished at the rate of 50 cents per cubic centimeter, or \$2.50 for 5 cc.

Serum can be obtained at the Manhattan Convalescent Serum Laboratory, Room 610, in the William Hallock Park Laboratory of the New York City Department of Health, 15th Street and East River, between the hours of 9 a m and 5 p m. on all weekdays except Saturday when the laboratory is open from 9 a m to 12 noon. At all other times serum can be obtained from Dr William L. Wheeler, Jr., 348 West 22nd Street (Chelsea 3-4149).

Further information regarding convalescent serum supplied by the laboratory can be obtained from Dr William Thalheimer, director.

## NOTES

The following promotions on the faculty and teaching staff of Harvard Medical School, effective next September were recently announced.

Oliver Cope, Francis C. Newton, Stanley J. G. Nowak and Robert Zollinger, assistant professors of surgery, Otto A. Bessey, associate in biological chemistry, Laurence B. Ellis and Maurice B. Strauss, associates in medicine, George M. Hass, associate in pathology, John A. V. Davies, Lewis W. Hill and Clement A. Smith, associates in pediatrics, Henry K. Beecher, associate in anesthesia, Robert E. Gross, John D. Stewart and Carl W. Walter, associates in surgery, and Henry D. Chadwick, lecturer on medicine.

## REPORTS OF MEETINGS

### HOSPITAL DAY AT THE BEVERLY HOSPITAL

The annual observation of Hospital Day was held at the Beverly Hospital on Saturday, May 13, in accordance with the custom of having the celebration on the nearest Saturday to National Hospital Day. On this day the former interns are invited to return and spend the day as guests of the staff of the hospital.

The program as presented by the staff was initiated with a surgical clinic, the first case being a partial gastric resection, and the second an exploratory laparotomy for carcinoma of the gall bladder. The operations were performed by Drs. Peer P. Johnson and Richard E. Alt. The following papers were then presented: Highlights in the Development of Modern Chemotherapy with Special Reference to Sulfapyridine, Dr. Barnard Todd, Technique of Nailing a Fractured Hip (Beverly Hospital Method), a motion picture, Drs. Johnson and Alt, presentation of cases by the house staff (Drs. DeWolfe, Epstein, Commette and Todd) with discussions by Drs. A. E. Parkhurst, Johnson, Paul E. Tynan and C. F. Branch.

### NEW ENGLAND SOCIETY OF PSYCHIATRY

The New England Society of Psychiatry held its sixty-fourth annual meeting at the Metropolitan State Hospital, Waltham, April 25, as the guests of Superintendent Roy D. Halloran. The meeting was attended by one hundred and sixty-nine members and guests.

Following inspection of the hospital and an excellent luncheon, the meeting was called to order by President Harlan L. Paine. A few words of welcome by Superintendent Halloran opened the meeting. The minutes of the previous meeting were read and adopted. The report of the treasurer and auditors was submitted and adopted as presented. The following were elected to full membership: Dr. Paul R. Felt, Middletown, Connecticut; Dr. Valerie R. Jurecek, Howard, Rhode Island; Dr. Adrian Scolten, Portland, Maine; Dr. George L. Wadsworth, Middletown, Connecticut.

The Examining Committee for the best papers published during the calendar year of 1938 recommended that the awards be given to the writers of the three following papers: The Effect of Adrenalin and Mecholyl in States of Anxiety in Psychoneurotic Patients by Erich Lindemann and Jacob E. Finesinger; Pick's Disease: A specific type of dementia by Ira C. Nichols and Walter C. Weigner; Studies in Convulsant Therapy: 1. Technique and Clinical Phenomena. 2. The Role of Alkalinization by Stanley Rochelle Dean.

The following were elected to office: president, Dr. Charles H. Dolloff, Concord, New Hampshire; vice president, Dr. Roy D. Halloran, Waltham, Massachusetts; secretary-treasurer, Dr. George A. Elliott, Middletown, Connecticut; counselors, Dr. George E. McPherson, Belchertown, Massachusetts, and Dr. Harlan L. Paine, North Grafton, Massachusetts.

The meeting adjourned following the reading of the paper, Some Observations on Patients Diagnosed as Having Schizophrenia, by Dr. John W. Thompson, of the Harvard Fatigue Laboratory and the research staff of the Metropolitan State Hospital, and Dr. William Corwin, of the Metropolitan State Hospital.

removed, as well as a cervical polyp. Catamenia began at fifteen and were regular with a twenty-eight-day cycle. The last period was February 16, making her due for delivery from November 23 to November 26. Her pregnancy had been uneventful. The delivery was normal and it was felt that the placenta was intact.

Convalescence after delivery was uneventful until November 26 at 10 a. m. when the hospital telephoned that she was flowing a great deal and had passed several large clots. She was given Ergoklonin, but since the flowing did not cease and it was estimated that she had lost about 500 cc of blood, it seemed wise to explore the uterus. The patient was typed and matched for possible transfusion. Her husband was found to be a compatible donor.

Under gas-oxygen anesthesia and strict asepsis, examination showed the uterus in good anterior position, well contracted and not much larger than a normal uterus five days post partum. The internal os admitted one finger. A definite piece of placenta was found adherent at the fundus and as much of this as possible was removed with the finger, dull curet and ovum forceps. An iodine pack was left in the uterus and was removed forty-eight hours later. After removal of the pack she passed a small clot and a piece of placental tissue. There was no flowing that night, but the next morning, November 29, she passed another clot which was mostly tissue. On December 1 she passed still another piece of tissue to which a good-sized clot adhered. Her pulse was under 70 and since her blood pressure had, at no time, gone below 110-120 systolic she was left alone. There was no bleeding after the expulsion of the clot on December 1, and she was discharged on December 11.

There was no abnormal flowing at the time of her first period after the birth of the baby.

DATE	RED-BLOOD CELL COUNT	HEMOGLOBIN
1938		%
Nov. 22	4 600 000	90
26	4 400 000	86
27	4 200 000	82
28	4 200 000	80
29	3 700 000	75
30	3 000 000	65
Dec. 1	3 250 000	65
2	3 100 000	62
3	3 320 000	68
4	3 420 000	74
6	3 250 000	73
8	3 800 000	75
10	3 900 000	82

The pathological report of the pieces of placenta obtained at the time of operation was as follows: "Decidua-like cells, extensive necrosis and chronic inflammation, a few cells of trophoblastic type, but no definite chorionic villi."

*Comment.* This is another illustration of the

commonest cause of bleeding in the puerperium. At the time of the delivery of the placenta it is clearly remembered that the placenta seemed intact. There was a great deal of blood lost at the time of the initial hemorrhage, and it is surprising that the blood picture does not bear this out. It is of course possible that the blood figures are incorrect. The convalescence after the removal of the piece of placenta was afebrile, but the blood examinations showed that there was considerable bleeding for several days after the pack had been removed. A second invasion of the uterus was contemplated, but the patient's general condition led one to conservatism. No transfusion was done because the blood examination ruled out its necessity.

It is often observed that the first catamenia after delivery may be very free. This is true more frequently in patients who are not nursing. One may expect a very free period in one who has bled as this patient did, but, fortunately, her first period was normal in every respect.

The strictest asepsis must be observed in all cases requiring intrauterine treatment. One can not emphasize this too much and must also appreciate that, if a curet is used, it must be used with extreme care and never in a rough manner.

## DEATHS

**McKEOUGH**—WILFRED A. McKEOUGH, M.D., of Haverhill, died May 26. He was in his forty-eighth year.

Born in Nova Scotia, he received his degree from the Tufts College Medical School in 1924. He was assistant to Dr. Francis E. O'Brien, superintendent of the Hampshire County Sanatorium, at the time of his death and had formerly been assistant medical officer at the State Sanatorium, Glencliff, New Hampshire.

Dr. McKeough was a member of the Massachusetts Medical Society and the American Medical Association. Three sisters survive him.

**PARTRIDGE**—CHARLES C. PARTRIDGE, M.D., of Melrose, died May 29. He was in his eighty-first year.

Dr. Partridge was a former member of the staff of the Boston City Hospital and practiced for many years in Hyde Park.

He was a former member of the Massachusetts Medical Society.

His daughter, and three sons survive him.

**THORNDIKE**—PAUL THORNDIKE, M.D., of West Roxbury, died May 28. He was in his seventy-seventh year.

Born in Beverly, he attended the public schools in Milwaukee, Wisconsin, and graduated from Harvard College in 1884. He received his degree from the Harvard Medical School in 1888, and became a member of the staff of the Boston City Hospital the same year. He continued his studies in Vienna and upon his return joined the Harvard faculty as assistant professor of genitourinary surgery. He later became surgeon-in-chief at the Boston

There will also be numerous exhibits from the departments of medicine, surgery, orthopedic surgery, photography, pathology, administration and roentgenology, the Harvard Infantile Paralysis Commission Clinic, and the School of Nursing

## SYMPOSIUM ON CARCINOMA OF THE TONGUE

A symposium on carcinoma of the tongue has been arranged by the staffs of the Massachusetts General, Collis P Huntington Memorial, Pondville and Palmer Memorial hospitals. A review of cases seen at each of these hospitals will be presented by Drs Roy E. Mabrey, Ira T Nathanson, Thomas J Anglem and Clifford C Franseen. Discussion will be opened by Dr Channing C Simmons.

The meeting will be held on Tuesday, June 13, on the roof of the Palmer Memorial Hospital, at 8 00 p m Refreshments will be served.

All members of the medical profession are cordially invited to attend.

LELAND S MCKITTRICK, M.D., *Chairman*

## LAWRENCE CANCER CLINIC

The regular Lawrence Cancer Clinic, to be held at the Lawrence General Hospital, 1 Garden Street, Lawrence, on Tuesday, June 20, at 10 00 a. m., will be a demonstration and teaching clinic for physicians, with Dr Channing C. Simmons, of Boston, present as consultant. Physicians of the north half of Essex County are invited to accompany any of their patients whom they desire to have this service or to send them with a note. A report will be returned to every physician who sends a patient. The service is gratis. Any physician is welcome to attend the clinic.

This clinic is endorsed by the Committee on Postgraduate Instruction of the Massachusetts Medical Society

J FORREST BURNHAM, M.D., *Chairman*

## GRADUATE FORTNIGHT OF THE NEW YORK ACADEMY OF MEDICINE

The twelfth annual Graduate Fortnight of the New York Academy of Medicine will be held in New York City from October 23 through November 3. The general topic is 'The Endocrine Glands and Their Disorders'.

As usual the clinical sessions will be held during the day at the various hospitals. During the evening, talks on different aspects of the general topic will be given at the Academy by men who are experts along such lines. The subtopics to be discussed are as follows: 'Historical Sketch of the Development of Endocrinology,' 'Physiology of Anterior Lobe of Pituitary Gland,' 'Pituitary Hypothalamic Syndromes,' 'Hypo- and Hyperpituitarism,' 'Therapeutic Application of Female Sex Hormones,' 'Physiology and Principal Interrelations of the Thyroid,' 'Hypothyroidism,' 'Hyperthyroidism,' 'Surgical Treatment of Hyperthyroidism and Other Diseases of the Thyroid,' 'The Adrenal Medulla,' 'Adrenal Insufficiency,' 'The Adrenal Cortex,' 'The Cushing Syndrome,' 'Neoplasms of the adrenal gland,' 'Overfunction of the Adrenal Cortex,' 'Relation of Diabetes to the Endocrine System,' 'The Influence of the Central Nervous System Upon Endocrine Activity,' 'Physiology and Pathology of Parathyroids,' 'Hyperparathyroidism,' 'Physiology of the Ovaries,' 'Physiology of Testes and Therapeutic Ap-

plication of Male Sex Hormones,' 'Puberty, Menstruation and Pregnancy' and 'Menopause.' A comprehensive exhibit of research, roentgenographic and pathologic material will be assembled to include diagnosis and treatment, clinical and laboratory diagnostic methods, action of drugs and other therapeutic measures. The library will exhibit books relating to the subject.

Registration fee for non-members is five dollars. Further details may be obtained by writing to the New York Academy of Medicine, 2 East 103 Street, New York City.

## SOCIETY MEETINGS AND CONFERENCES

### CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY, JUNE 12

#### MONDAY JUNE 12

Symposium on the Public Health Significance of the Virus and Rickettsial Diseases. Harvard School of Public Health, 55 Shattuck Street, Boston.

#### TUESDAY JUNE 13

Symposium on the Public Health Significance of the Virus and Rickettsial Diseases. Harvard School of Public Health, 55 Shattuck Street, Boston.

\*10 a. m. 12 30 p. m. Tumor Clinic, Boston Dispensary.

\*8 p. m. Symposium on Carcinoma of the Tongue. Palmer Memorial Hospital.

#### WEDNESDAY JUNE 14

Symposium on the Public Health Significance of the Virus and Rickettsial Diseases. Harvard School of Public Health, 55 Shattuck Street, Boston.

#### THURSDAY JUNE 15

Symposium on the Public Health Significance of the Virus and Rickettsial Diseases. Harvard School of Public Health, 55 Shattuck Street, Boston.

#### FRIDAY JUNE 16

Symposium on the Public Health Significance of the Virus and Rickettsial Diseases. Harvard School of Public Health, 55 Shattuck Street, Boston.

\*10 a. m. 12 30 p. m. Tumor Clinic, Boston Dispensary.

#### SATURDAY JUNE 17

Symposium on the Public Health Significance of the Virus and Rickettsial Diseases. Harvard School of Public Health, 55 Shattuck Street, Boston.

Because of the holiday the usual staff rounds at the Peter Bent Brigham Hospital, conducted by Dr Henry A. Christian, will be omitted.

Open to the medical profession.

SEVENTIETH ANNIVERSARY  
OF THE CHILDREN'S HOSPITAL

The seventieth anniversary celebration of the Children's Hospital will be held in Vanderbilt Hall, Friday and Saturday, June 9 and 10

\* \* \*

## MEDICAL PROGRAM

Friday, June 9

- 8 00 a. m.—9 45 a. m. Selected operations by surgical and orthopedic services
- 9 45 a. m. First scientific session Dr W E. Ladd, chief of the Department of Surgery and clinical professor of surgery, Harvard Medical School  
Opening remarks Dr Ladd.  
Words of welcome. Dr Paul Emerson, president of the Children's Hospital Alumni Association  
Remarks and announcements Dr P J Mahoney, secretary of the Children's Hospital Alumni Association  
The Children's Hospital Today Dr Sidney Farber, secretary of the visiting staff of the Children's Hospital.
- 10 15 a. m.—12 30 p. m. Certain Aspects of the Protein Metabolism of Premature Infants Dr S Z. Levine, professor of pediatrics, Cornell University Medical College.  
Correlation of the X-ray and Autopsy Findings in Lipoid Pneumonia Dr R. S. Bromer, assistant professor of radiology, Graduate School of Medicine, University of Pennsylvania  
Some Studies of Body Water in Normal and Abnormal Growth Dr Bengt Hamilton, associate professor of pediatrics, University of Illinois  
Studies on the Blood Level of Co-Enzyme I (Cozymase) in Nicotinic Acid. Dr S O. Dexter, Jr, The Rockefeller Institute Hospital  
The Bridle of Theages Dr J A. Nutter, clinical professor of orthopedic surgery, McGill University  
Intra mesenteric Diverticula. Dr J W. Duckett, associate professor of clinical surgery, Baylor University  
Children's Surgery as a Specialty Dr H. C. Coe, Seattle, Washington

Training Crippled Children Dr J F Pohl (Talk and moving pictures)

1 45 p. m.—4 15 p. m. Second scientific session Chairman Dr F R. Ober, chief of Department of Orthopedic Surgery, and professor of orthopedic surgery, Harvard Medical School.

The Calcium Balance in a Case of Legg's Disease. Dr J A. Johnston, pediatrician-in-chief, Henry Ford Hospital, Detroit, Michigan

Hypoproteinemia Dr A. A. Weech, associate professor of pediatrics, Columbia University Medical School, the Babies' Hospital.

Membrane Formation at Lipoid Protoplasmic Interfaces Dr G M. Hass, instructor in pathology, Harvard Medical School.

Human Locomotion A summary of twelve years of research Dr R P. Schwartz, associate professor of surgery, University of Rochester

Acute Appendicitis in Childhood. Dr Henry Hudson, Jr, assistant in surgery, Harvard Medical School

On the Acid-Soluble Phosphorus Compounds of Red Blood Cells Dr G M. Guest, associate professor of pediatrics, University of Cincinnati, College of Medicine

Coronary Artery Occlusions Dr Monroe Schlesinger, Jr, Associate in pathology, Harvard Medical School, pathologist to the Beth Israel Hospital.

Saturday, June 10

- 8 00 a. m.—9 45 a. m. Selected operations by surgical and orthopedic services
- 9 45 a. m.—12 00 m. Third scientific session Chairman, Dr S Burt Wolbach, chief of the Department of Pathology and Shattuck Professor of Pathology, Harvard Medical School.  
Photometry and Vitamin A. Dr P C. Jeans, professor of pediatrics, University of Iowa  
New Shelf Operation for Subluxation of the Hip-Joint. Dr E. W. Ryerson, senior orthopedic surgeon, St. Luke's Hospital, Chicago, and formerly professor of orthopedic surgery, Northwestern University Medical School.  
Hydrometrocolpos in Infancy Drs J W. Chamberlain and P J. Mahoney, Boston University School of Medicine.  
Studies in the Physiology of Premature Infants Dr J L. Wilson, associate professor of pediatrics, Wayne University College of Medicine, Detroit, Michigan  
The Care of Prematures Isabelle Jordan, R N, assistant superintendent of nurses, the Children's Hospital, Boston (Moving picture.)  
Surgical Management of the Patent Ductus Arteriosus With summary of four successfully treated cases. Dr R. E. Gross, instructor in surgery, Harvard Medical School  
Metabolism of Sulfanilamide. Dr J S. Harris, associate in pediatrics, Duke University Medical School
- 12 00 m.—1 00 p. m. Clinicopathological conference conducted by the chiefs of the four services pediatrics, surgery, orthopedic surgery and pathology
- 1 00 p. m. Closing remarks by Dr K. D. Blackfan, chief of the Department of Pediatrics and Thomas Morgan Rotch Professor of Pediatrics, Harvard Medical School

## PYELITIS, URETERITIS AND CYSTITIS CYSTICA\*

FRANK S. PATCH, MD†

MONTREAL

**P**YELITIS, ureteritis and cystitis cystica constitute definite pathologic conditions in which cysts are formed in the mucosa or submucosa of the renal pelvis, ureter and bladder respectively.

The first mention of such a condition was made by Morgagni in 1761. Since then it has been described by many pathologists. Litten in 1876 made the first microscopic study. He believed that the cysts resulted from the proliferation of mucous membrane, forming mucosal cysts, or that they were derived from pre-formed glands. Subsequent writers, including Osler, suggested a parasitic origin from coccidial infection. Today the hypothesis advanced by von Limbeck in 1887 and von Brunn in 1893 is generally accepted by most authorities. These authors ascribed the genesis of the cysts to the downward projection, from the inferior layer of the epithelial cells of the mucosa, of epithelial nests, now known as Limbeck-Brunn nests, though more commonly as Brunn's nests. Subsequently, a lumen is developed in the center of the nest by a degenerative or what is more probable a secretory process. At this point the condition may evolve in two directions: first, to the formation of cysts with distended lumina, lined with flattened epithelium, pyelitis, ureteritis or cystitis cystica; second, by a further development of the secretory process, so well described by Stoerk and Zuckermandl. While the lumen in the epithelial cell nests is still small, the surrounding cells assume a concentric radiating position about it. The inner layer takes on definite characteristics of secreting epithelium, with basally placed nuclei. The inner portion of the cells becomes light, and in it are seen granules which stain with a mucin stain. In other words, the epithelial cells have taken on the characteristics of a secreting epithelium, with the production of true

mucin‡. The resulting condition is known as pyelitis, ureteritis or cystitis glandularis. The cystic and glandular forms are thus very closely related, both resulting from a metaplasia in the epithelium of the urinary tract.

This view of the development of cystitis glandularis has not had universal acceptance. It has been challenged notably by François, who championed the theory that it results from the embryonal inclusion of germinal cells of the lower intestinal tract. This would seem very difficult to combat in the case of the exstrophied bladder, where cystitis cystica and glandularis are found extremely well developed. Their occurrence in the renal pelvis is not so easily explained. The studies of Enderlen and Formiggini, however, would appear to be conclusive. They discovered quite independently that the exstrophied bladders of newborn infants revealed no signs of any cystic or glandular formation. In other words, cystitis cystica and glandularis are postnatal acquisitions.

From a clinical point of view, there is nothing very characteristic of these conditions, apart from a constriction of the ureter, which may follow the ureteral variety. Usually they are quite overshadowed by the underlying condition responsible for the inflammation, of which they are merely a part.

The changes mentioned are not the result of a special form of inflammation but are rather the result of alterations in the bladder epithelium which may develop in the course of any long-continued, not too intense inflammation. While the inciting cause may be found in any kind of chronic irritation, it would appear that the conditions of which we are speaking develop most commonly in the presence of certain special irritating factors. Stone is a frequent concomitant. Inflammatory exudates from infected kidneys may

Read at a meeting of the New England Branch of the American Urological Association, Boston, November 17, 1938.

†Professor of urology and head of the Department of Surgery, McGill University Faculty of Medicine, urologist, Montreal General Hospital.

‡It should be pointed out that the mucus-like material which is found in the urine of infected bladders is not a true mucin, but a pseudomucin composed of nucleoproteins derived from degenerating leukocytes.

## BOOK REVIEWS

*Roentgen Diagnosis of the Extremities and Spine* Albert B Ferguson 435 pp New York Paul B Hoeber, Inc., 1939 \$12.00

From the Roentgenological Department of the New York Orthopaedic Hospital, under the authorship of its director, Dr A B Ferguson, comes this valuable study of roentgen ray technic and an interpretative discussion of the uses of the roentgen rays in the diagnosis of lesions in the spine and extremities. The keynotes of the study are the author's methods of analysis of the effects of trauma and disease on the various tissues involved in the osseous framework of the body how these tissues react to inflammatory processes within or external to the bone, the distinctions that should be made between atrophy and decalcification, between cortical thickening and hypertrophy and between the different types of osseous density, that is, those caused by pyogenic agencies and syphilis or tuberculosis, and the characteristics that should enable one to distinguish a fracture line from congenital osseous defects that occur in the various bones of the body and the

ways of distinguishing between calcification and ossification, all of which observations are helpful in differentiating pyogenic lesions from tumors, and so forth

Calcifications occurring post traumatically, after periosteal rupture and in the walls of bursas, also come in for discussion. In Chapter 3 is a consideration of decalcification, loss of structure and loss of substance, and how these defects are associated with the anemias, malacias, old age atrophies, atrophies of disuse, Kümmell's disease, and so forth. In Chapter 4 the significance of soft tissue swellings as indicative of already visible, nearby, osseous lesions, or such lesions not yet roentgenologically detectable but soon to appear, is discussed. Chapter 5 defines the pathognomonic indications of malignancy in diaphyseal bone, and in the following chapter the features that distinguish abnormalities of metaphyseal bone are considered, these peculiar features being due to the nature of the capillary circulation in the metaphysis and the fact that it is there that changes due to growth in bone take place. A chapter on the inherent disturbances of bone formation includes the chondrodystrophies, chondrodysplasias, achondroplasias, ostitis fibrosa, and so forth. The chapters on fractures and their healing contain much information in respect to the phases of callus formation and other matters of interest to those who deal with fracture repair. The development of the epiphyses and the occurrence of anomalous small-bone masses in various locations have a chapter devoted to their description. The final sections concern non-osseous tissues,—such as loose bodies in or about joints,—Charcot's disease and other degenerative lesions, bursal effusions, the arthritides, tuberculous and non tuberculous lesions and lumbosacral anomalies.

The wealth of material on which the author could draw and the admirable reproduction of his more than 500 illustrations, supplemented, as these are, by 262 brief case histories from the hospital records, make this volume a most helpful guide to roentgen diagnosis

*Health at Fifty* Edited by William H. Robey 299 pp Cambridge Harvard University Press, 1939 \$3.00

Among the agencies operating to promote the health of the people, the free public lectures delivered in Boston by the faculty of the Harvard Medical School hold high rank. Since the quality of these addresses warrants the widest possible distribution, twelve have been included in the book under the above-designated title.

In addition to the importance of having individuals know about the causes and effects of the commoner fatal and disabling diseases, a general appreciation of the economic and sociologic implications of them will bring about a more active co-operative spirit among intelligent and public spirited laymen, which will promote progress in the health programs underway by organized medicine.

The subjects dealt with by these eminent specialists are heart disease, cancer, blood pressure, overweight and underweight, rheumatism, menstruation and the menopause, care of the eyes, vitamins, glands of internal secretion, the family medicine cabinet, mental health and the problems of old age. The writers have avoided the use of technical terms and have shown marked ability in presenting facts in an interesting and instructive manner. This volume should be in all circulating libraries, for the people who will profit most by reading it will not be among those who ordinarily frequent medical libraries.

Practitioners may well advise patients to read every chapter in the book during convalescent periods, when the mind is in a receptive mood. Other editions should follow this publication.

pathologist of the Jewish General Hospital, Montreal. It was found in a case of calculous pyonephrosis in which a few cysts were discovered in the

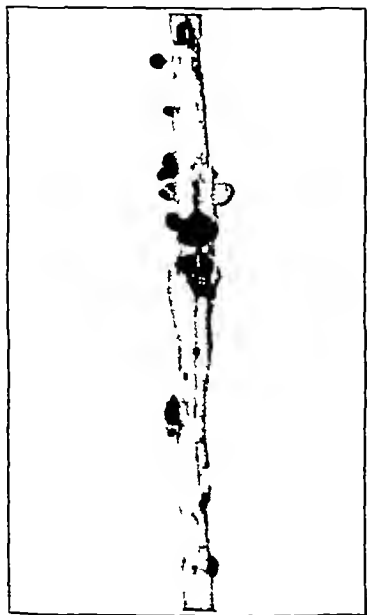

FIGURE 1

*Photograph of a postmortem specimen from a case of ureteritis cystica showing numerous thin walled cysts in the wall of the ureter*

pelvis and upper ureter. Evidently there had been a long-continued renal infection, associated with the calculi (Fig 2)

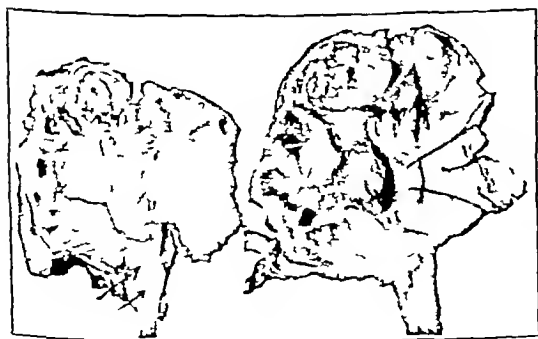

FIGURE 2

*Photograph of a postmortem specimen from a case of calculous pyonephrosis showing two cysts in the ureter and one cyst in the pelvis*

The main interest in this presentation is with cases in which a clinical diagnosis has been made. Only within the last decade has pyeloureteritis cystica been diagnosed clinically. From the literature I have been able to collect 8 cases, which are here briefly reviewed

**Case 1** Jacoby in 1929 appears to have been the first to make a clinical diagnosis of ureteritis and pyelitis cystica. The patient was a 40-year-old man, who gave a history of chronic urinary infection of 20 years duration. Renal calculi were present in the left kidney. The bladder showed the typical picture of cystitis cystica. The pyelogram showed a cystic dilatation of the calices and mottled filling defects down the entire left ureter.

**Case 2** Joelson in 1929 reported a case in a woman of 44 who entered the hospital because of intermittent hematuria of 13 years duration. Calculi were present in both kidneys. Cystitis cystica was present. Ureteropyelography revealed dilated pelves and ureters. Small filling defects were noted in the pelves and marked ones in the ureters.

**Case 3** Kindall in 1933 confirmed his clinical diagnosis by operation and biopsy. A man of 41 entered the hospital with a right renal colic. He had passed a stone. There were no cysts in the bladder. A clinical diagnosis of pyeloureteritis cystica was confirmed by an exploratory operation. This is the first recorded case in which a clinical diagnosis was confirmed by operation and biopsy. The condition was treated by ureteral dilatation and instillation of 2 per cent silver nitrate solution. Clinical and pyelographic improvement followed.

**Case 4** Fites case (1935) was also confirmed by operation. The patient, a woman of 41, had suffered from urinary frequency for many years, with a recent exacerbation of bladder pain and frequent and painful urination. There was a calculus in the right kidney. The bladder was normal. The ureter showed a moth-eaten appearance. Operation revealed a kidney pyonephrotic in its lower half, which was removed by heminephrectomy. A biopsy from the ureter was secured. The ureter was studded with small, tense, glistening cysts.

**Case 5** Chevassu (1936) reported a case of a woman of 51 with a history of pyuria for 26 years. The x-ray film showed a calculus in the right kidney. Ureteropyelograms showed characteristic mottlings. At the operation for the removal of the stone, a section of pelvis was removed for histological study. There were no cysts in the bladder.

**Cases 6, 7 and 8** In 1936, Hinman reported 3 cases. The first was a woman of 64, who entered the hospital complaining of severe right lumbar pain of 2 months duration, with transient attacks of hematuria, and with increased frequency of urination. Pyuria was noted. Cysts were seen in the bladder. Both ureters were dilated. Numerous non-opaque filling defects were observed in both ureters, particularly in their lower two thirds. At the upper ends of both ureters were noted large spherical dilatations, with marked ureteral constrictions immediately beneath. The calices were distended on both sides and there was marked constriction of the calculopelvic junctures. The pain and bladder symptoms improved after a course of ureteral dilatations and the instillation of a 1 per cent silver nitrate solution. The filling defects in the ureter disappeared, but the intrapelvic changes were unaltered.

His second case was that of a man of 37, who gave a history of pain in the left renal area, with chills, fever, frequency, hematuria, burning and pyuria of 1 year's duration. Three months before admission he had a similar attack. There remained a constant aching pain in the left loin, with frequency, nocturia and burning micturition. Cystoscopy revealed a well marked cystitis cystica. Both ureters were dilated and scattered filling defects

be the starting point. Mechanical influences alone may bring about the change. For instance, cystic and glandular formations have been found in the bladder in aseptic chronic urinary retention, secondary to prostatic adenoma. When mechanical influences are superadded to infection, they are seen in their most marked development, as in the mucosa of the exstrophied bladder. Chronic cystitis is nearly always present in both cystitis cystica and cystitis glandularis. Where it is not associated, it is presumed to have been present previously, even in intrauterine life.

The condition may develop with extraordinary rapidity. Stoerk and Zuckerkandl report a case of well-marked cystitis cystica and glandularis which developed in forty-two days. While these authors claim that the condition remains during the life of an individual, our own repeated clinical observations show that it may completely disappear. In one case of cystitis cystica, while the underlying infective condition was unchanged, disappearance of bladder cysts was noted, and in a case of cystitis cystica and cystitis glandularis their disappearance followed soon after the removal of the underlying etiologic factors, a ureterocele and a bladder calculus, by cystostomy and temporary bladder drainage.

The experimental work of Gianti is most illuminating. In carrying out studies on urinary tuberculosis, Gianti introduced capsules containing tubercle bacilli into the bladders of rabbits, by means of a suprapubic cystotomy. The capsules became encrusted and calcified, epithelial nests were formed about them and the typical pathologic picture of cystitis cystica developed. He also produced the condition by curettage of the mucosa. The condition disappeared in three or four months.

In a previous communication, I endeavored to show the relation between leukoplakia and squamous-celled carcinoma, and at a later date Dr Rhea and I dealt with the relation between cystitis glandularis and mucus-secreting adenocarcinoma of the bladder. In our studies since then we have found the exstrophied bladder a most fertile field of study. Here the two factors of mechanical irritation and inflammation have ample scope, and it is not surprising to discover the two processes of leukoplakia and cystitis cystica or glandularis richly developed side by side. Both conditions, we believe, represent two forms of metaplasia. Both are likely to undergo a further transformation or metamorphosis to carcinoma, squamous-celled in the one case, adenocarcinoma in the other, the two types of cancer which are found most frequently in the exstrophied bladder, a viscus which is extremely prone to develop malignant changes.

According to Morse, who reviewed the subject in 1928, the literature contains reports of not more than 60 cases of pyelitis cystica, ureteritis cystica or cystitis cystica, mainly of pyelitis cystica and ureteritis cystica. Since that date there have been some additional reports, which, however, do not convince me that the condition is as rare as the paucity of reports would indicate. Certainly cystitis cystica is not a rare condition. Our own experience has shown us that isolated cysts are found not infrequently about the bladder neck, and that even a well-marked development is not unusual. Some years ago, a short study revealed 12 cases in which material obtained at operation or autopsy was available. Morse, in a study of 125 autopsies, practically consecutive, recognized 3 macroscopically as pyelitis cystica, ureteritis cystica or cystitis cystica, while cell nests, buds or cysts were found microscopically in 108 cases. During the cystoscopic examination of 190 cases, he found cystitis cystica in 33, or 17 per cent. MacKenzie and Beck in 1936, in 50 autopsies of women subjects, found 16 cases with epithelial nests at the bladder neck and 11 with cysts in the same area.

The finding of a well-marked development of pyelitis cystica and ureteritis cystica is much more unusual. To the 28 cases collected by Morse in 1928, Hinman has added 13, exclusive of the cases based on purely clinical diagnosis, which are dealt with below. Among these are those reported by Urquhart, who, in a series of autopsies in Egypt on patients infected with *Schistosomium haematobium*, found 6 cases of ureteritis cystica. All these cases were discovered at autopsy or operation. To them we shall add 2 cases coming under our own observation but discovered post mortem.

The first is a specimen preserved in the Pathological Museum of McGill University. To Dr C B Keenan of the Royal Victoria Hospital, Montreal, I am indebted for the privilege of reporting it.

A woman of eighty-four was admitted to the hospital with a fracture of the neck of the femur. Suffering from auricular fibrillation during her treatment, she developed two very large decubitus ulcers over her sacrum. She gradually failed, and died two months later. So far as can be learned, there was a history of long-continued urinary infection. Autopsy revealed among other conditions a necrotic cystitis. At one point the bladder had sloughed through into the peritoneal cavity and produced a generalized peritonitis from which the patient died. Pyemic abscesses were found in both kidneys. Both ureters were studded with small thin-walled cysts lined with flattened epithelium (Fig 1).

The second case is a postmortem specimen for which I am indebted to Dr D P Seecof, late

third, are seen several longitudinal filling defects, which are suggestive of a ureteritis cystica (Fig 4)

In this case, in view of the long history of chronic urinary infection, the presence of cystitis cystica, the dilated and strictured ureters and the filling defects in the left ureter, we have made a clinical diagnosis of ureteritis cystica, with a suspicion of pyelitis cystica. Ureteral dilatation, or the little we have been able to perform, seems to have been followed by some improvement.

**Case 10** A man of 71 was admitted to the medical service of the Montreal General Hospital in June, 1937, complaining among other things of a nocturia of 3 years duration. He had a chronic bronchitis and hypertensive cardiovascular disease. For the previous 3 years he had had frequency, by day every 2 hours, by night three to four times. In the 3 weeks previous to admission the symptoms had been greatly aggravated. He passed small quantities of urine every 30 minutes, and complained of burning and dribbling. For several days he had been unable to sleep on account of persistent suprapubic and groin pain. His prostate was moderately enlarged. The urine contained a moderate quantity of pus, 1 to 5 cells per high-power field. The frequency subsided somewhat after resting in bed.

As the routine x-ray films showed a shadow in the left kidney region, suggesting a calculus, the patient was seen by the Urological Service on June 10

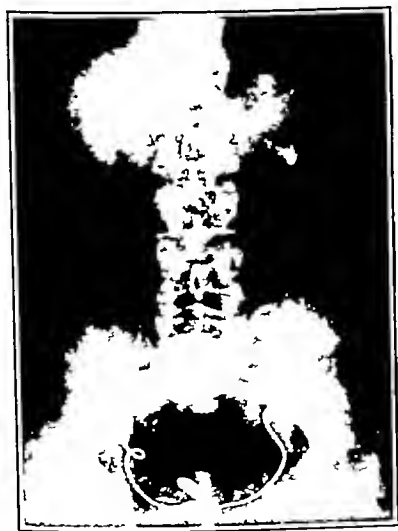

FIGURE 5 Case 10

*X-ray film showing a calculus in the left kidney*

Cystoscopy showed a slight prostatic enlargement. The ureters were catheterized, the right easily, the left with difficulty and only partially. No pus was found in the ureteral specimens. Pyelography showed the opaque shadow to be situated in the inferior calyx of the left kidney (Fig 5). This pelvis was incompletely filled. Multiple circular filling defects were observed on both ureters and the right kidney pelvis.

Four days later the patient was again cystoscoped. On this occasion, a more careful search of the bladder revealed the presence of two cysts at the bladder neck. Garceau catheters were passed up both ureters for 5 cm. Culture of the right kidney urine showed *Staphylococcus aureus*. That of the left side gave no growth. Pyelograms showed

clearly the presence of the filling defects in the left ureter and left pelvis (Fig 6)

The patient had a definite renal insufficiency, his urea concentration factor being only 22. On account of this, his age and his hypertensive cardiovascular condition, operation for the removal of the calculus was neither desired nor urged. Similarly, further ureteral dilatations were not possible.

FIGURE 6 Case 10

*Composite urogram. Note the filling defects in both ureters and kidney pelvises*

While operative confirmation was not secured, it is believed that this is a definite case of pyeloureterocystitis cystica.

#### SYMPTOMS

There are no symptoms pathognomonic of the condition, since they are found in patients suffering usually from long-standing urinary tract infections, and the symptoms are identical with those of such an infection or conditions such as calculus, so often associated. From this fact it happens that the condition is usually found in older individuals. That age is not an essential requisite is seen in the fact that the exstrophic bladder shows the condition in its most marked development. It occurs about equally in both sexes, though one would expect from the more numerous obstructive factors present in men that they would be more likely to suffer from it. Calculus is frequently found. Five of the 10 clinical cases of pyeloureteritis cystica had renal stone. Occasionally copious hematurias are reported. This symptom has not infrequently been responsible for a diagnosis of tumor. Only at the nephrectomy was the true condition revealed. There is a very definite tendency to bilaterality. The bacteriological flora is very variable, including *Staphylococcus*

were observed in the ureterogram. The right ureteropelvic junction was narrowed and there was a slight spherical dilatation of the pelvis at upper end of the ureter above it. The calculopelvic junctions on both sides were narrowed.

Harrison's third case was that of a woman of 55, who gave a history of burning, urgency and nocturia of 10 years' duration. Her kidney had been removed for nephroma 1 year after the first onset of symptoms. Cystoscopy revealed well-marked cystitis cystica. No filling defects were noted in the ureter. There was narrowing of the calculopelvic junctions, with dilatation of the calyces. There was slight narrowing of the ureteropelvic junction. In this case we diagnosed a pyelitis cystica, because of the presence of cystitis cystica and the pyelographic change in the pelvis which we believe to be characteristic of a pyelitis cystica.

To these 6 cases we add 2 others in which we have made a clinical diagnosis of pyeloureteritis cystica. Ten cases, therefore, have been diagnosed by urological study, though in 3 only, the cases of Kindall, Fite and Chevassu, was there confirmation by operation and biopsy. In these 3 cases the presence of calculus indicated operative interference.

Case 9. A farmer, a veteran of the World War, was first seen by us in 1926, then aged 29, complaining of urinary frequency and cloudy urine, present since his war

bladder office was found matted with small translucent cysts, most numerous on the floor and extending backward on the trigone. Both ureteral specimens showed 29 to 30 pus cells per high-power field. Both catheters were blocked by obstructions about 10 cm. up the ureter. X-ray studies with sodium iodide revealed dilated ureters below the point of obstruction (Fig. 3). No filling defects were seen.

It was not possible to do anything more for the patient at this time owing to his unwillingness to follow any treatment. He was in the hospital on several occasions in 1936 and 1937 for brief examinations. On three occa-

FIGURE 4 Case 9

FIGURE 3 Case 9.

Ureterogram in which a clinical diagnosis of ureteritis cystica was made, taken before ureteral dilatation. Note the bilateral ureteral block and the suspicious filling defects in ureters.

service. The frequency was intensified after exposure to cold and fatigue. Occasional pains were felt in the region of the left kidney. At this time urological study was advised, but it was not carried out until 1931, when the patient was admitted to the Montreal General Hospital. There was slight tenderness in both costovertebral areas. The urine contained a moderate quantity of pus. There was frequent emptying of the bladder by day and two to six times at night. X-ray films showed no calculus. On cystoscopy the

long single attempts at ureteral dilatation were made, with some improvement, as on the patient's last visit in August, 1937, he stated that his frequency was better than it had been for many years. He suffered, however, from low back pain and fatigue on exertion, and the urine still contained pus. Urine culture revealed no bacterial growth. At cystoscopy, cysts were always found on the trigone and around the bladder neck. The lower ureters were still tortuous and dilated. Only in August, 1937, were we able to demonstrate any filling in a kidney, and that was the right one. Intravenous pyelograms were most unsatisfactory because of the poor visualization. The combined renal function was definitely impaired. The urea concentration factor on August 14, 1937, was only 33.

The cystoscopic report of August 14, 1937, reads as follows: "The internal orifice and trigone are covered with cysts. Several cysts are noted close to the ureteral orifices." Both kidney specimens contained pus. Pyelography on this occasion revealed the following: "The tip of the catheter on the right side has reached a level between the 4th and 5th lumbar vertebrae. On the left side the catheter has reached the level of the upper border of the 11th thoracic spine. The pelvis and calyces of the right kidney are filled. No injection on the left. There is slight dilatation of the pelvis of the right kidney, with rather irregular blunting of the upper calyx. Both ureters are tortuous and dilated. On the left ureter, in its lower

third, are seen several longitudinal filling defects, which are suggestive of a ureteritis cystica (Fig 4)

In this case, in view of the long history of chronic urinary infection, the presence of cystitis cystica, the dilated and strictured ureters and the filling defects in the left ureter, we have made a clinical diagnosis of ureteritis cystica, with a suspicion of pyelitis cystica. Ureteral dilatation, or the little we have been able to perform, seems to have been followed by some improvement.

**Case 10** A man of 71 was admitted to the medical service of the Montreal General Hospital in June, 1937, complaining among other things of a nocturia of 3 years duration. He had a chronic bronchitis and hypertensive cardiovascular disease. For the previous 3 years he had had frequency, by day every 2 hours, by night three to four times. In the 3 weeks previous to admission the symptoms had been greatly aggravated. He passed small quantities of urine every 30 minutes, and complained of burning and dribbling. For several days he had been unable to sleep on account of persistent suprapubic and groin pain. His prostate was moderately enlarged. The urine contained a moderate quantity of pus, 1 to 5 cells per high power field. The frequency subsided somewhat after resting in bed.

As the routine x-ray films showed a shadow in the left kidney region, suggesting a calculus, the patient was seen by the Urological Service on June 10

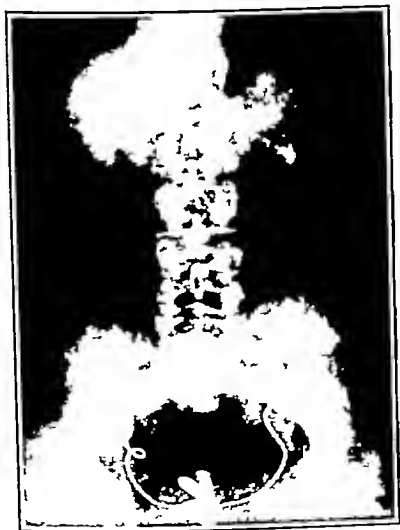

FIGURE 5 Case 10

*X-ray film showing a calculus in the left kidney*

Cystoscopy showed a slight prostatic enlargement. The ureters were catheterized, the right easily, the left with difficulty and only partially. No pus was found in the ureteral specimens. Pyelography showed the opaque shadow to be situated in the inferior calyx of the left kidney (Fig 5). This pelvis was incompletely filled. Multiple circular filling defects were observed on both ureters and the right kidney pelvis.

Four days later, the patient was again cystoscoped. On this occasion, a more careful search of the bladder revealed the presence of two cysts at the bladder neck. Garceau catheters were passed up both ureters for 5 cm. Culture of the right kidney urine showed *Staphylococcus aureus*. That of the left side gave no growth. Pyelograms showed

clearly the presence of the filling defects in the left ureter and left pelvis (Fig 6)

The patient had a definite renal insufficiency, his urea concentration factor being only 22. On account of this, his age and his hypertensive cardiovascular condition, operation for the removal of the calculus was neither desired nor urged. Similarly, further ureteral dilatations were not possible.

FIGURE 6 Case 10

*Composite urogram. Note the filling defects in both ureters and kidney pelvis*

While operative confirmation was not secured, it is believed that this is a definite case of pyeloureteritis cystica.

#### SYMPTOMS

There are no symptoms pathognomonic of the condition, since they are found in patients suffering usually from long-standing urinary tract infections, and the symptoms are identical with those of such an infection or conditions such as calculus, so often associated. From this fact it happens that the condition is usually found in older individuals. That age is not an essential requisite is seen in the fact that the exstrophic bladder shows the condition in its most marked development. It occurs about equally in both sexes, though one would expect from the more numerous obstructive factors present in men that they would be more likely to suffer from it. Calculus is frequently found. Five of the 10 clinical cases of pyeloureteritis cystica had renal stone. Occasionally copious hematurias are reported. This symptom has not infrequently been responsible for a diagnosis of tumor. Only at the nephrectomy was the true condition revealed. There is a very definite tendency to bilaterality. The bacteriological flora is very variable, including *Staphylococcus*

were observed in the urograms. The right ureteropelvic juncture was narrowed and there was a slight spherical dilatation of the pelvis or upper end of the ureter above it. The calculopelvic junctures on both sides were narrowed.

Hinman's third case was that of a woman of 45, who gave a history of burning, frequency and nocturia of 10 years duration. Her kidney had been removed for hematuria 1 year after the first onset of symptoms. Cystoscopy revealed well marked cystitis cystica. No filling defects were noted in the ureter. There was narrowing of the calculopelvic junctures, with dilatation of the calices. There was slight narrowing of the ureteropelvic junctures. In this case he diagnosed a pyelitis cystica, because of the presence of cystitis cystica and the pyelographic change in the pelvis which he believes to be characteristic of a pyelitis cystica.

To these 8 cases we add 2 others in which we have made a clinical diagnosis of pyeloureteritis cystica. Ten cases, therefore, have been diagnosed by urological study, though in 3 only, the cases of Kindall, Fite and Chevassu, was there confirmation by operation and biopsy. In these 3 cases the presence of calculus indicated operative interference.

**Case 9** A farmer, a veteran of the World War, was first seen by us in 1926, then aged 29, complaining of urinary frequency and cloudy urine, present since his war

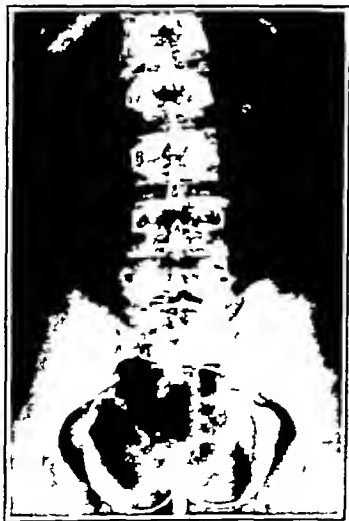

FIGURE 3 Case 9

*Ureterogram in which a clinical diagnosis of ureteritis cystica was made taken before ureteral dilatation. Note the bilateral ureteral block and the suspicious filling defects in ureters.*

service. The frequency was intensified after exposure to cold and fatigue. Occasional pains were felt in the region of the left kidney. At this time urological study was advised, but it was not carried out until 1931, when the patient was admitted to the Montreal General Hospital. There was slight tenderness in both costolumbar areas. The urine contained a moderate quantity of pus. There was frequency every hour by day and two to six times at night. X ray films showed no calculus. On cystoscopy the

bladder orifice was found studded with small translucent cysts, most numerous on the floor and extending backward on the trigone. Both ureteral specimens showed 20 to 30 pus cells per high power field. Both catheters were blocked by obstructions about 10 cm. up the ureter. X ray studies with sodium iodide revealed dilated ureters below the point of obstruction (Fig 3). No filling defects were seen.

It was not possible to do anything more for the patient at this time owing to his unwillingness to follow any treatment. He was in the hospital on several occasions in 1936 and 1937 for brief examinations. On these occa-

FIGURE 4 Case 9

*Composite urogram taken after ureteral dilatation. Note the filling defects in the left lower and right upper ureters.*

sions single attempts at ureteral dilatation were made, with some improvement, as on the patient's last visit in August, 1937, he stated that his frequency was better than it had been for many years. He suffered, however, from low back pain and fatigue on exertion, and the urine still contained pus. Urine culture revealed no bacterial growth. At cystoscopy, cysts were always found on the trigone and around the bladder neck. The lower ureters were still tortuous and dilated. Only in August, 1937, were we able to demonstrate any filling in a kidney, and that was the right one. Intravenous pyelograms were most unsatisfactory because of the poor visualization. The combined renal function was definitely impaired. The urea concentration factor on August 14, 1937, was only 33.

The cystoscopic report of August 14, 1937, reads as follows: "The internal orifice and trigone are covered with cysts. Several cysts are noted close to the ureteral orifices. Both kidney specimens contained pus. Pyelography on this occasion revealed the following: 'The tip of the catheter on the right side has reached a level between the 4th and 5th lumbar vertebrae. On the left side the catheter has reached the level of the upper border of the left ischial spine. The pelvis and calices of the right kidney are filled. No injection on the left. There is slight dilatation of the pelvis of the right kidney, with rather irregular blunting of the upper calyx. Both ureters are tortuous and dilated. On the left ureter, in its lower

agency has developed, more radical procedures may be required, even the sacrifice of a kidney

### SUMMARY

The subject of pyelitis, ureteritis and cystitis cystica is reviewed

The literature of the subject is briefly reviewed, and 10 cases of pyelitis and ureteritis cystica in which a clinical diagnosis was made are reported, including 2 observed by the author

The genesis of the cysts is discussed and their evolution to cystitis glandularis is described

These conditions are probably not so rare as previously thought

The diagnosis of pyelitis cystica and ureteritis cystica is possible by urological study

The treatment is discussed

1225 Bishop Street.

### DISCUSSION

Dr. W. D. BIEBERBACH, Worcester. In 1933 a patient was admitted to the Urological Service at the Worcester City Hospital, at which time she was cystoscoped because of costovertebral tenderness, pain in the flank and hematuria. Following the cystoscopy the patient was greatly improved for three months, after which there was a recur-

rence of the hematuria. The peculiar shadow shown in her ureter presented a picture which was thought to be a papilloma or some similar growth. This finding plus the hematuria led to operation. At operation the ureter was apparently normal except for a distinct, fixed kink several centimeters below the ureteropelvic junction. Just below the kink, beady masses could be felt. In the ureter were found multiple growths with an appearance suggestive of papilloma. Because of this, ureteronephrectomy was decided on. The specimen showed multiple small cysts which studded the ureter and renal pelvis. I had the opportunity of recystoscopying this patient, and I might say that nothing was observed except inflammatory changes in the bladder. In 1936 there was the same appearance. I recystoscoped this patient recently and there was the same condition in the bladder. There were petechial spots in the wall of the bladder and on the trigone and dome. There were a few cysts that had the size and appearance of tapioca. I did a ureteropyelogram by injecting the pelvis with sodium iodide. I injected the ureter and pelvis with 10 cc. of the 7 per cent solution. It showed nothing of importance. There was a normal-appearing bladder. I then used a Woodruff catheter, which helped to bring out the vacuoles quite plainly. Of course we did not recognize this condition, which was identified by the pathologist. Probably if we had recognized it we should have treated it conservatively, as Dr. Patch has suggested.

Dr. J. E. KERNEY, Providence, R. I. I should like to ask Dr. Bieberbach if these cases of ureteritis cystica could not have been treated by desiccation of the cysts. I believe that in addition to the treatment outlined by Dr. Patch, it might be well to desiccate them.

Dr. J. B. HICKS, Boston. While I was a member of the Lahey Clinic it was my privilege to do some 2000 cystoscopies. In this group I saw 2 cases that might be classified as cystitis cystica. The first patient, whom I saw ten years ago, was a woman thirty years old. There was no evidence of inflammation. She was treated by fulguration. She passed out of my care so that I was unable to follow her. The other case was that of a woman whom I saw in consultation with another doctor. She had been having painless hematuria for at least two years. Because of the hematuria, diagnoses such as stone, tumor and infection were considered. Cystoscopy showed definite evidence of bladder neck obstruction. Urine cultures, sediments and guinea pig inoculations were negative. Most of the time the urine was clear. The outstanding symptom was massive quantities of blood. The patient developed uremia and died. The presence of chronic inflammation in these conditions makes me think of infection as a possible etiologic agent. Possibly some of the viruses may be responsible for this condition. Dr. Patch did not mention tonight whether the urines were cultured in these cases. I should like him to bring this out.

Dr. RICHARD CHUTE, Boston. I have never seen a recognizable case of ureteritis cystica. A few cysts in the bladder are very common. Offhand I can think of a half-dozen patients with a few cysts of the bladder.

Dr. MYRON HAHN, JR., Boston. I have two small x-ray pictures here which I should like to show. The first is that of a man who came to the outpatient department complaining of pain in his back. The large cysts can be seen very plainly. One was protruding from the ureteral orifice. Puncturing these cysts relieved the backache. There was no operation. The patient returned to the clinic later, still without backache, and refused operation. The other picture brings out what Dr. Patch said about the condition at the lower end of the ureter, simulating

*aureus*, streptococcus, *Bacillus coli* and *Bacillus pyocyaneus*

#### DIAGNOSIS

The presence of cysts above the surface of the bladder in the region of the bladder neck makes recognition of cystitis cystica by cystoscopic observation fairly easy (Figs 7 and 8) Cystitis

FIGURE 7

*Cystoscopic appearance of the bladder in a case of bilateral nephrolithiasis, with cystitis cystica and suspected ureteritis cystica*

glandularis presents an irregular or mammillated appearance difficult to distinguish from cystitis cystica, except in microscopic sections At other times,

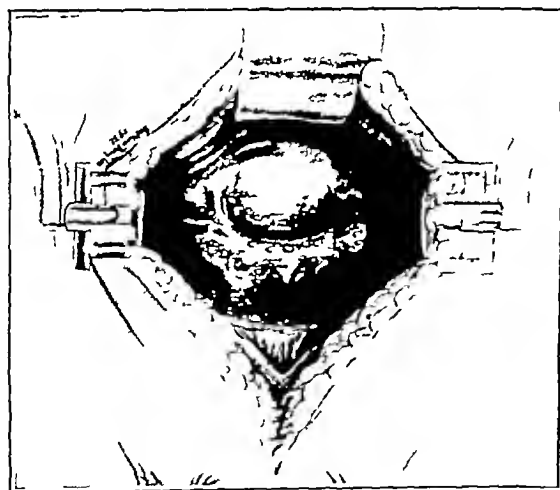

FIGURE 8

*Photograph of a drawing made at operation in a case of cystitis cystica and cystitis glandularis There were numerous cysts on the bladder base The patient had a vesical calculus and a ureterocele Complete cure followed operation*

cystitis glandularis may present itself as an ulceration, red and bleeding, or may be covered with a necrotic membrane One of our most characteristic sections was secured at autopsy No gross lesion

was observed The condition was not suspected until routine microscopic sections taken from the bladder neck revealed typical cystic and glandular cystitis, with associated leukoplakia

The diagnosis of pyelitis and ureteritis cystica is not so simple, but it should be obvious that with our present methods of urological study they may be readily recognized Wherever cystitis cystica is noted, the upper urinary tract should be given a more than usually close scrutiny Cystitis cystica is usually associated with a pyelitis or ureteritis cystica, or both, though not always In our second case it was only after noting the ureterographic picture that a careful search of the bladder revealed the presence of a few cysts in that viscous

Of prime importance in diagnosing ureteritis or pyelitis cystica, is the occurrence of vacuoles, bubbles or non-opaque filling defects in the urogram Before their true significance was realized, they were frequently confused with air bubbles or papillomas Another finding of significance is a dilatation, tortuosity or constriction of the ureters In the pelvis, there is found a spherical calculic dilatation, with narrowing of the calculopelvic junctures Hinman is insistent on the value of this sign, as also on the narrowing at the ureteropelvic juncture, with a spherical dilatation above. One must confess that such a finding in the absence of the typical vacuoles or filling defects is not entirely inconsistent with a diagnosis of chronic pyelonephritis

#### TREATMENT

This should very naturally be directed to the underlying inflammatory process Search for a causative factor should be our first objective If this factor is an obstructive one its removal where possible may bring about a complete subsidence of symptoms, and, as our own experience has taught us, particularly in the bladder variety, a complete disappearance of the cysts

Such therapy is easier to achieve in cystitis cystica, where the obstructing condition may be easily recognized and dealt with by operative therapy Where the condition is found in the upper urinary tract, the situation is not quite so satisfactory Some palliation may be possible, apart from that afforded by the removal of a calculus As constriction of the ureter is frequently present, and in any event the bulging cysts constitute undeniable obstacles to the free course of the urine, repeated ureteral dilatations, recommended by Kindall and followed by Hinman and ourselves, seem the logical procedure Associated with dilatation, Kindall and Hinman advise the instillation of silver nitrate, in a 1 or 2 per cent solution

If conservative measures fail, and renal insuffi-

blocks must have played a prominent part in the fatal ending.

I am convinced that if a careful watch is maintained, the conditions of ureteritis and pyelitis cystica will be found more frequently than in the past.

I lean very strongly to the view that a metaplastic process is responsible for the production of pyelitis, ureteritis and cystitis cystica, and that in its further development it may end in cystitis glandularis and even in malignancy.

## THE INTRAMUSCULAR USE OF THE MONOETHANOLAMINE SALT OF CEVITAMIC ACID IN PATIENTS WITH VITAMIN C DEFICIENCY\*

EUGENE L. LOZNER, M.D.,† FREDERICK J. POHLE, M.D.,‡ AND F. H. LASKEY TAYLOR, PH.D. §

BOSTON

REPEATED clinical and laboratory studies have demonstrated that the oral administration of pure cevitic acid to the large majority of patients deficient in vitamin C causes a prompt amelioration of symptoms and a restoration of the vitamin C of the blood to normal concentration<sup>1,2</sup>. In certain patients, however, who cannot tolerate cevitic acid by mouth, or in whom gastric anacidity or the presence of pathologic changes in the bowel leads to destruction or poor absorption of the vitamin, the parenteral administration of vitamin C is an established clinical necessity.<sup>2,3</sup> In such patients intravenous administration has been widely used. This route, however, is associated with considerable loss of the vitamin through the kidneys as the renal threshold is exceeded,<sup>4,5</sup> and has the additional disadvantage of requiring venepuncture.

The intramuscular use of cevitic acid seems to offer a method of escaping these disadvantages. This relatively strong acid, however, if given intramuscularly and not neutralized causes considerable sloughing of the tissues.<sup>6</sup> Neutralization by sodium hydroxide or bicarbonate gives an injectable substance readily absorbed and utilized.<sup>6,7</sup> To make this preparation is time consuming, and requires considerable care if sterility is to be obtained without loss in potency. The monoethanolamine salt of cevitic acid is a neutral salt and can be prepared so as to form a sterile stable solution.<sup>||</sup> This paper reports an investigation of the intramuscular use of this material in 3 patients with vitamin C deficiency, and compares its effect with the oral and intravenous administration of crystalline cevitic acid.<sup>||</sup>

### METHODS

Patients were chosen for study who gave a history indicating marked reduction of vitamin C in their diet and who exhibited hemorrhagic manifestations of scurvy. Their blood showed a complete absence of the vitamin.

During the control period each patient was given a "house diet" free from citrus fruits. At the end of this period the twenty-four-hour specimen of urine and a sample of blood were analyzed and found to contain no cevitic acid. Each patient was then given 1 gm. of vitamin C by mouth and the blood level of the vitamin was determined after a half, one and a half, two and a half, four and twenty-four hours. Urine was collected for the twenty-four-hour period after the administration of the vitamin, in 2 of the patients the first five hour excretion was collected separately.

After the initial oral tolerance for vitamin C was concluded the patients were permitted to remain on the basic diet until the vitamin C was again absent from both blood and urine. The observations were then repeated following the intramuscular injection of 1 gm. of cevitic acid in the form of the monoethanolamine salt. When the effects of this administration of the vitamin had disappeared, as shown by a return to approximately the same initial level of cevitic acid in the blood, the observations were repeated after giving intravenously 1 gm. of crystalline cevitic acid.

In 1 patient the therapeutic use of monoethanolamine cevitamate was attempted at a dosage of 100 mg. a day given intramuscularly for eight days. In this individual the observations following the oral administration of 1 gm. of cevitic acid were repeated after the cevitic acid level in the blood had reached a normal figure.

The urine was collected in dark bottles and kept on ice, acetic acid and chloroform being used as a preservative. The vitamin C present in the reduced form was determined by the method of Faulkner and Taylor.<sup>4</sup> The reduced cevitic acid

ureteritis cystica but actually due to a papilloma of the ureter. This appeared to be one of those tumors that responded well to radiation. After a preliminary course of radiation the patient was operated on. At operation the kidney tumor and ureter were removed. This was a case of tumor implants and not ureteritis cystica.

DR. F. F. WEINER, Brockton. We have seen 2 cases of pyeloureteritis cystica at the Brockton Hospital. In one the patient was a woman of sixty whose chief complaint was hematuria. She was sent in for examination, and pyelograms were made. The diagnosis was very easy. The patient refused treatment because the symptoms stopped. There was an advanced condition of ureteritis cystica on one side, and a small number of vacuoles on the other. This emphasizes the bilaterality of the condition, which Dr. Patch has pointed out. The other case was that of a young man of twenty-three with hematuria and nothing else. In this case there were only three or four vacuoles in the kidney pelvis and upper ureter. We believed that the correct diagnosis was pyelitis and ureteritis cystica. We did nothing further because after his pyelography the patient had no further symptoms. I believe that palliative treatment was the proper procedure, because we do not know whether removing the kidney on that side would have prevented the occurrence of cysts on the other side. I also think that the other case was best handled conservatively. It was done three years ago and the patient is apparently in good health. She is getting along very well without further treatment.

DR. WILLIAM C. QUINBY, Boston. The subject of pyeloureteritis cystica which Dr. Patch has presented so conclusively forms a definite pathologic picture, but one in which we must be careful not to confuse our thoughts, for the phenomenon of cystic formation is not a disease in itself but merely the pathologic response of the urinary epithelium to some antecedent cause. In my experience this cause has usually been a deep-seated pyelonephritis of bacterial origin. Therefore, in using the term "pyeloureteritis cystica" one does not describe a disease but merely a condition.

The epithelium of the urinary tract has the property of undergoing metaplasia as a result of various forms of stimuli. Furthermore, we are all familiar with the so-called bullous edema sometimes seen in the floor of the bladder as a result of obstructive changes of the return circulation without the presence of bacteria. I refer to the bullous edema around the ureteral orifice before the passage of a calculus. Similarly, in conditions of renal infection of long standing, the obstruction of perivesical lymph channels may be so continuous as to cause the formation of cysts which, owing to metaplasia, form an epithelial lining with active secretion, finally resulting in the picture of cystic ureteritis which Dr. Patch has described. In a few well marked cases this cystic formation may be sufficiently extensive to cause mechanical obstruction in the ureter. But since all these ureters are somewhat dilated by the disease process, I do not see how further instrumental dilatation can bring anything more than transient relief. If permanent relief is to be achieved, one must be able to control the underlying cause, and this, as I have said, is usually a severe pyelonephritis—a condition in which cure is always difficult if not impossible. That an occasional cyst in the pelvis or ureter can be the cause of gross hematuria I very much doubt. Certainly bleeding cannot fairly be ascribed to such a condition unless every other source for it has been excluded.

DR. BIEBERBACH. I should like to ask Dr. Patch about our 2 cases as regards the bacteriology. Both had clear urines, the cultures of the urine were negative and the sediments were negative. In the case of the woman, prior to operation she had an infection on the opposite side which was due to the staphylococcus. She got along satisfactorily with this cystic condition. In this case the condition was not secondary to infection. The kidney function was normal, dye appearing in four minutes. The blood nonprotein nitrogen was normal.

DR. ROSS MINTZ, Boston. I should like to ask Dr. Patch whether he considers cystitis cystica and cystitis glandularis as pathological entities. Is cystitis cystica an end result, or is cystitis glandularis an end result of cystitis cystica?

DR. PATCH. It seems that my endeavor to summarize has caused confusion in the minds of some, and I am grateful to Dr. Quinby for clarifying the situation so ably, and drawing your attention to the fact that these different varieties of cystic inflammation are not clinical entities. This will appear quite clearly, I hope, in the published version of my paper.

With regard to the question as to the value of desiccation of the cysts, I should point out that this procedure does not deal with the underlying condition responsible for them, and therefore gives only temporary relief. In the presence of such a condition, the important considerations are the diagnosis of the underlying cause and its relief, whether it be calculus, obstructive factor or whatever condition is responsible for the chronic inflammation that has resulted in the cystic formations.

Ureteral dilatation does have a value in cases where the cystic accumulations in the ureter have obstructed the ureter, by producing an improvement in drainage through it. In cases where there is no obvious indication for operative interference, ureteral dilatation is to be recommended as a palliative measure. In several of the reported cases, as in one of ours, it was followed by definite improvement.

With regard to the frequency of these conditions of cystic formation, they occur much more frequently than is generally thought to be the case. In my paper, I quoted Morse, who found that cysts were present in the bladder of 17 per cent of 190 cases examined cystoscopically. In the bladder, its recognition is naturally easier than in the ureter or the kidney pelvis. I am convinced, however, that more careful study of pyelograms, and in particular more careful ureterography, will reveal cases which have formerly been overlooked.

Dr. Hicks asked a question as to the cultures in these cases. The bacterial flora is quite varied, but without any special significance.

Answering Dr. Quinby as to why these cases should bleed so freely, I am afraid that I cannot give a satisfactory explanation. That they do bleed at times, and very freely, is an undoubted fact. Frequently a diagnosis of tumor has been made and the kidney removed, and the true condition revealed by the pathologist. I have thought that obstruction to urinary outflow played an important role. Certainly ureteral dilatation has produced a definite improvement in my experience and that of others. I assume that dilatation effected a freer urinary outflow.

The obstruction of the ureters by the masses of cysts must have played a part in producing death in some of the cases. This is well shown in two of the Peter Bent Brigham cases in which uremia caused death and the lesions were discovered post mortem. In these cases, while there were other obstructive factors, the ureteral

intramuscular administration of 100 mg of cevitic acid as the monoethanolamine salt. In eight days the blood level rose from 0.12 to 0.81 mg per 100 cc of blood plasma. The oral administration of 1 gm of vitamin C at this time showed a prompt rise in the blood plasma cevitic acid to 1.77 mg per 100 cc. Data for the two oral tolerance

## CONCLUSIONS

The intramuscular injection of the monoethanolamine salt of cevitic acid presents a simple and effective way of administering vitamin parenterally when need for this type of injection is indicated.

There were no immediate or delayed, local or systemic reactions following its use in the 3 patients studied.

Its intramuscular administration was followed by a prompt increase in the vitamin C of blood. The loss of vitamin C in the urine was not so marked as when crystalline cevitic acid was given intravenously.

A patient with marked vitamin C deprivation was saturated in eight days by the daily intramuscular injection of 100 mg of cevitic acid as the monoethanolamine salt.

We are indebted to Miss Nancy Marean for technical assistance.

‡24 hour values include five hour values.

oral administration of 1 gm of vitamin C there was little change in the subnormal cevitamic acid levels of the blood of these patients. No vitamin was found in the urine during the twenty-four hours following ingestion of cevitamic acid. In 1 individual it was at first suspected that the absorption of the vitamin might have been impaired. Glucose-tolerance studies on this patient, however, revealed no abnormality of sugar absorption as measured by the form of the blood-sugar curve.

When 1 gm of vitamin C dissolved in isotonic salt solution was given by vein there was a prompt rise of the blood level of the vitamin, followed by marked excretion into the urine as the renal threshold for the vitamin was exceeded. In confirmation of the observations of Wright, Liliental and MacLenathan,<sup>10</sup> the excretion occurred chiefly in the first five hours. The twenty-four-hour excretion of cevitamic acid ranged between 174 and 265 mg, or between 17 and 27 per cent of the amount of vitamin given.

Following the intramuscular administration of 1 gm of cevitamic acid in the form of the monoethanolamine salt, there was again a prompt rise in the blood level of cevitamic acid. The rise

following administration. Most of this excretion occurred in the first five hours following administration. The rate of rise in the blood level

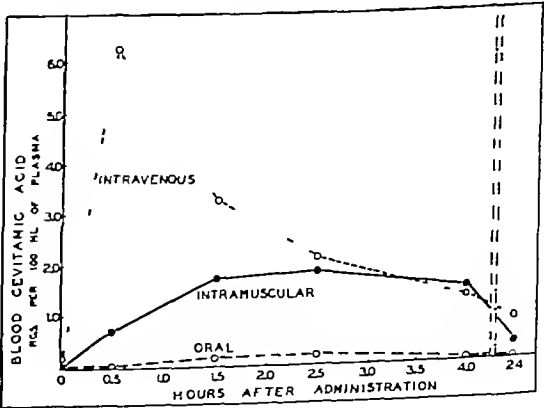

FIGURE 1 The effect of administration of 10 gm of vitamin C on the concentration of cevitamic acid in the blood plasma of a patient (Case 3) with vitamin C deficiency

of the vitamin indicated a good rate of absorption. One patient (Case 3) was saturated by the daily

intramuscular administration of 100 mg of cevitic acid as the monoethanolamine salt. In eight days the blood level rose from 0.12 to 0.81 mg per 100 cc. of blood plasma. The oral administration of 1 gm of vitamin C at this time showed a prompt rise in the blood plasma cevitic acid to 1.77 mg per 100 cc. Data for the two oral tolerance

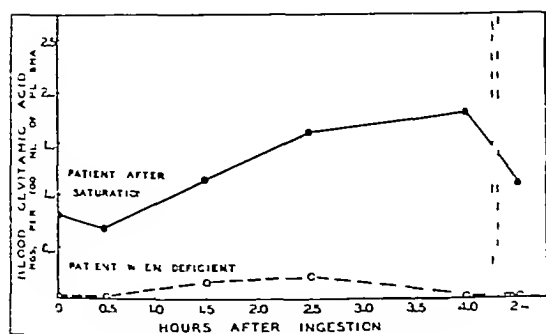

FIGURE 2.

*The effect of the oral administration of 1.0 gm of vitamin C on the concentration of cevitic acid in the blood plasma of a patient (Case 3) with vitamin C deficiency before and after saturation with the intramuscular administration of 100 mg of monoethanolamine cevitate daily for eight days*

tests are summarized in Table 1, and the curves are shown in Figure 2. One hundred and sixteen milligrams of cevitic acid was excreted into the urine during the twenty-four hours following the ingestion of the vitamin C, the largest amount being excreted between the sixth and the twenty-fourth hours.

Eleven intramuscular injections of a solution of the monoethanolamine salt of cevitic acid in doses ranging between 0.1 and 1.0 gm were given, without any immediate or delayed, local or systemic reactions.

## CONCLUSIONS

The intramuscular injection of the monoethanolamine salt of cevitic acid presents a simple and effective way of administering vitamin C parenterally when need for this type of injection is indicated.

There were no immediate or delayed, local or systemic reactions following its use in the 3 patients studied.

Its intramuscular administration was followed by a prompt increase in the vitamin C of the blood. The loss of vitamin C in the urine was not so marked as when crystalline cevitic acid was given intravenously.

A patient with marked vitamin C deprivation was saturated in eight days by the daily intramuscular injection of 100 mg of cevitic acid as the monoethanolamine salt.

We are indebted to Miss Nancy Marean for technical assistance.

## METRAZOL TREATMENT OF DEPRESSIONS\*

FRANCES COTTINGTON, MD,† AND ARTHUR J. GAVIGAN, MD‡

WORCESTER, MASSACHUSETTS

ON THE basis of the data published by Low et al.,<sup>1</sup> which indicated favorable results with Metrazol therapy in the affective psychoses, in 1938 we began an investigation of a group of 20 depressed women patients at the Worcester State Hospital. The purpose of this paper is to indicate the results obtained and to describe certain phenomena observed in the course of the treatments. Within recent months several reports have appeared in the literature. Low states that 13 of his 16 treated manic-depressive patients recovered, Bennett<sup>2</sup> announced uniformly good results in 21 cases, Cook<sup>3</sup> called his 4 recoveries in 5 cases promising and dramatic, and Serko<sup>4</sup> cited 2 cases with recovery.

The rationale of Metrazol therapy in depressed states is at present unknown. Bennett<sup>2</sup> has stated that the effects are probably due to the ability of the treated patient to prove to himself his willingness to undergo punishment, with subsequent resolution of guilt and lifting of the depression. The various theories underlying the *modus operandi* of Metrazol which have been advanced by Von Meduna,<sup>5</sup> Friedman<sup>6</sup> and Gellhorn<sup>7</sup> in the treatment of schizophrenia may or may not be applicable to the treatment of the depressions. It is beyond the intention of this report to enter this controversial field.

## METHOD

Prior to the beginning of treatment all patients were examined in order to determine any physical disability contraindicating treatment. Laboratory examinations included x-ray examination of the chest and blood and urine studies. The finding of a systolic blood pressure over 150 mm of mercury, a diastolic blood pressure over 90 mm, marked retinal arteriosclerosis, impaired cardiac function or any febrile illness was each considered as a contraindication.

Metrazol (Bilhuber-Knoll) was administered intravenously in 10 per cent aqueous solution, the initial dose was 3 cc, which was increased by 1-cc increments until the convulsive threshold was reached. The dose was further increased by 1-cc amounts when tolerance to the drug, as manifested by the absence of the grand-mal seizure, devel-

oped during the course of treatments. Doses were given three times weekly, not less than one hour following and one hour preceding meals. They were continued until remission occurred. In 3 cases treatments were discontinued after the apparent maximum improvement had been attained.

The greatest improvement following individual treatments seemed to occur after seizures of the grand-mal type. After seizures of the petit mal, abortive-tonic or confusional type, many patients became more agitated and apprehensive.

No formal psychotherapy was administered during the course of treatment. However, reassurance was necessary from time to time for some patients in order to allay apprehension regarding the treatments.

The only complication encountered was occasional bilateral dislocation of the mandible, which was usually reduced spontaneously after relaxation of the muscles. It is our opinion that careful nursing procedure during and immediately following the seizure is the most important factor in reducing the possibility of fractures and dislocations which may occur during the course of therapy. Two nurses were employed during each seizure to hold the patient in such a way as to prevent abduction at the hips and shoulders.

## CLINICAL MATERIAL AND RESULTS

Of the 20 patients treated, those who were between forty and sixty years of age and who had had no previous attacks of mental disorder were classified as involutional psychoses. When paranoid ideas were prominent these patients were considered to be of the paranoid type, otherwise they were considered to be of the melancholic type. Those patients below forty, and also those who had had previous attacks of mania or depression, were considered as having manic-depressive psychoses. All were of the depressed type. There were 3 castrates (Cases 1, 3 and 7), and 6 patients (Cases 4, 5, 10, 11, 12 and 18) were known to have passed through the menopause. The duration of mental illness prior to the institution of treatment ranged from two months to five years. Some of these patients had been treated with amphetamine (Benzedrine), Progynon, Emmenin or Theelin with no noteworthy effects, these treatments had been discontinued at least three months before treatment with Metrazol was begun.

The essential data concerning these patients, the

nature of the Metrazol treatment and the clinical results are presented in Table 1. The time which has elapsed since treatment was discontinued varies from one to five and a half months, the average period being three months.

#### DISCUSSION

Of the 20 patients treated, 17 (85 per cent) had complete remission of symptoms and 3 (15 per

cent) of time following seizures. Delusions and delusional ideas were in all cases the last of the symptoms to disappear, and were put forward by the patients with diminishing conviction as treatment progressed.

The patients who underwent remissions were able to return at once to their previous occupations. Information concerning them was obtained by monthly interviews and correspondence after their

	19	45	5 (depressed)	1 1/2	0	12	7	8	Remission
	20	36	1 (manic)	1 2/3	0	14	11	7	Remission

cent) manifested definite improvement. Of the 3 patients who underwent no remission but did improve, all were over fifty years of age, and 2 had minimal retinal arteriosclerosis. There was no correlation between the duration of illness prior to the institution of treatment and the degree of success. In the 3 patients who did not have a remission, the duration of illness ranged from eight months to five years. There was no correlation between the age of the patient or the duration of illness and the number of treatments required to produce a remission.

Motor activity was the first symptom to become normalized in all cases except Cases 4, 7 and 14, in which all symptoms disappeared suddenly. Agitated patients became quiet and obvious tenseness disappeared, retarded patients became sufficiently active to participate in productive work. Following the return to a normal degree of activity the mood lifted—in some cases suddenly and completely, in others for increasingly longer pe-

riods of time following seizures. One patient (Case 12) returned voluntarily for a second course of treatments, stating that on resuming a difficult domestic situation she noted recurrence of depression and feelings of guilt, she again underwent a full remission. With this exception all patients stated that there had been no return of their former symptoms. Tension and anxiety were at times manifested during the interviews following remission, when some patients discussed certain phases of their personal life. These states were, however, readily overcome by the patients themselves before the termination of the interview. This material had not been expressed during the psychosis. No emotional reaction was evidenced in discussing ideas expressed during the acute period of the psychosis.

During the course of treatments, 7 patients (Cases 4, 5, 8, 11, 14, 16 and 19) had somatic complaints, for example backache, pains in the joints, palpitation, weakness, epigastric pain, prick-

## METRAZOL TREATMENT OF DEPRESSIONS\*

FRANCES COTTINGTON, M.D.,† AND ARTHUR J. GAVIGAN, M.D.‡

cent) manifested definite improvement. Of the 3 patients who underwent no remission but did improve, all were over fifty years of age, and 2 had minimal retinal arteriosclerosis. There was no correlation between the duration of illness prior to the institution of treatment and the degree of success. In the 3 patients who did not have a remission, the duration of illness ranged from eight months to five years. There was no correlation between the age of the patient or the duration of illness and the number of treatments required to produce a remission.

Motor activity was the first symptom to become normalized in all cases except Cases 4, 7 and 14, in which all symptoms disappeared suddenly. Agitated patients became quiet and obvious tenseness disappeared, retarded patients became sufficiently active to participate in productive work. Following the return to a normal degree of activity the mood lifted—in some cases suddenly and completely, in others for increasingly longer pe-

riods of time following seizures. One patient (Case 12) returned voluntarily for a second course of treatments, stating that on resuming a difficult domestic situation she noted recurrence of depression and feelings of guilt, she again underwent a full remission. With this exception all patients stated that there had been no return of their former symptoms. Tension and anxiety were at times manifested during the interviews following remission, when some patients discussed certain phases of their personal life. These states were, however, readily overcome by the patients themselves before the termination of the interview. This material had not been expressed during the psychosis. No emotional reaction was evidenced in discussing ideas expressed during the acute period of the psychosis.

During the course of treatments, 7 patients (Cases 4, 5, 8, 11, 14, 16 and 19) had somatic complaints, for example backache, pains in the joints, palpitation, weakness, epigastric pain, prick-

ling sensations in the scalp and blurred vision. Physical, x-ray and ophthalmoscopic examinations gave no evidence of any somatic basis for these symptoms. It was noted that these complaints were more numerous following seizures of the petit-mal or confusional type, and were less frequent or absent following seizures of the grand-mal type. The complaints made their appearance as the depression lifted and as the ideas of guilt or persecution diminished, and in every case had disappeared by the time remission had occurred. It seemed possible that repressed material was being symbolically expressed in the form of somatic symptoms.

During the course of therapy, 6 patients (Cases 4, 10, 14, 16, 19 and 20) complained of loss of memory for certain material. However, examination revealed that there was no memory defect, and that some of the patients were apparently complaining of inability to concentrate, many of the patients showed, however, considerable affectivity when some of the "forgotten" ideas were recalled, indicating that they might have been wishfully forgetting (repressing) this material.

#### SUMMARY

Metrazol therapy was carried out in a group of 20 depressed women patients, classified as having

involuntional and manic-depressive psychoses. The age range was twenty-eight to fifty-nine, and the patients had been ill from two months to five years. Treatments were administered three times weekly beginning with a dose of 3 cc of 10 per cent aqueous solution of Metrazol, which was increased as necessary to obtain typical grand-mal seizures, the treatments were discontinued when remission or considerable improvement had taken place. In this series, 17 patients underwent full remission of symptoms and 3 manifested improvement. The order of disappearance of psychotic symptoms is described and certain clinical features associated with this form of treatment are discussed. These results indicate that further trial with Metrazol is warranted in the treatment of depressions of these types.

## CALCIFIC AORTIC STENOSIS—A CLINICAL ENTITY

MEYER TEXON, MD\*

NEW YORK CITY

THE last decade has witnessed notable advances toward the fuller recognition of calcific aortic stenosis as a clinical entity. Data have been assembled producing a picture so characteristic that an increase in the frequency with which this diagnosis is correctly made may be expected. When it is appreciated that several other entities, including angina pectoris and coronary thrombosis, may be simulated by calcific aortic stenosis, its importance from a practical as well as an academic view can be seen.

#### HISTORY

Although Monckeberg<sup>1</sup> is justly credited with the first comprehensive pathological identification of calcific aortic stenosis and Christian<sup>2</sup> is similarly credited for emphasizing it as a clinical entity, the

older literature abounds with cases of calcific aortic stenosis with typical clinical pictures. Cases are found in which, despite incomplete data, the diagnosis could very reasonably have been made had the present-day improved clinical methods been available. Thus, Boneti<sup>3</sup> in 1700 stated that Rayger in 1672 reported sudden death in a patient with calcific aortic cusps. Lloyd<sup>4</sup> in 1846 reported sudden death in a man of fifty-three with calcific aortic stenosis and a hypertrophied heart. Gautier<sup>5</sup> in 1860 reported sudden death in a boy of twelve with calcific aortic stenosis and a normal mitral valve. Peacock<sup>6</sup> reported sudden death in a man of twenty-three who had calcific aortic stenosis and aortic insufficiency with a hypertrophied heart. Budin and Decaudin<sup>7</sup> reported a woman of forty-eight who died suddenly; they noted calcific aortic stenosis and aortic insufficiency with thickened,

\*Associate physician and physician in charge of the Cardiac Clinic, Knickerbocker Hospital, New York City.

fused, calcific valve cusps Wilks and Moxon<sup>8</sup> as early as 1875 called attention to the connection between aortic stenosis and sudden death

The morbid anatomy of aortic stenosis has received much detailed study, dating especially since 1904, when Mönckeberg's<sup>1</sup> classical paper defined the pathologic alterations produced in this condition. Since then notable studies in this field have been made by Margolis, Ziellessen and Barnes,<sup>9</sup> Sohval and Gross,<sup>10</sup> Lesnick and Schlesinger<sup>11</sup> and Clawson et al.<sup>12</sup>

Christman<sup>2</sup> predicted the possibility of the x-ray demonstration of cardiac calcification in vivo, and recently Sosman and Wosika<sup>27</sup> first reported such a case

In the field of clinical physiology, the pulsus tardus et parvus was long recognized by the older writers. Recent contributions concerning the physiology and hemodynamics of aortic stenosis have been made by Eyster, Meek and Hodges<sup>13</sup> in 1927, Katz, Ralli and Cheer<sup>14</sup> in 1928 and Green<sup>15</sup> in 1936

Important summaries of extended clinical observations of calcific aortic stenosis have been published by Contratto and Levine,<sup>16</sup> McGinn and White,<sup>17</sup> Willius<sup>18, 19</sup> and Willius and Camp<sup>20</sup>

#### ETIOLOGY

Campbell and Shackle<sup>23</sup> investigated the etiologic factors in 296 cases of all types of aortic valvular disease. They found that acute rheumatism accounted for 200 cases, syphilis for 53, atheroma for 20 and all other causes for 21. Contratto and Levine<sup>16</sup> reviewed 180 cases of aortic stenosis and found a definite history of rheumatic fever in 57 (32 per cent). They believe that many additional cases could have been classified in this latter category if more careful histories had been elicited and if patients could have more readily recalled minor yet typical rheumatic episodes early in life. They concluded that rheumatic fever is the most frequent and most important cause of aortic stenosis.

Uniformity of opinion concerning the etiology of calcific aortic stenosis as distinct from aortic stenosis in general has not yet been reached. Mönckeberg<sup>1</sup> believed the former to be a degenerative disease with a resulting deposit of calcium. Cabot<sup>21</sup> acknowledged infection as a factor but believed the nature of the infectious process to be different from that occurring in the presence of rheumatic valvular disease. Margolis, Ziellessen and Barnes<sup>9</sup> claimed an inflammatory basis in some cases and a degenerative process in others. Boas<sup>22</sup> believed calcific aortic stenosis to be rheumatic in origin. Sohval and Gross<sup>10</sup> in their close study of calcific sclerosis of the aortic valve concluded

that the disease was purely degenerative showing practically none of the stigmas of rheumatic activity. They suspected that the process depended on individual predisposition to collagen involution and deposition of lipid and calcium.

Christman<sup>2</sup> has been impressed with the frequent history of rheumatism in early life, and, contrary to his own view in 1928,<sup>28</sup> now thinks that the lesion is rheumatic in origin. Mallory<sup>24</sup> believes that calcareous aortic stenosis is very rarely rheumatic in origin. Although Willius<sup>18</sup> holds that the process is inflammatory, its exact nature still being unknown, he points out the following factors against rheumatic fever as the etiologic agent: the overwhelming predominance of the disease in men relatively late in life, the low incidence of rheumatic fever (21 per cent of 77 reported cases), and the rarity of pericardial involvement. As an argument against an atherosclerotic genesis he called attention to the remarkable paucity of atherosclerosis in portions of the cardiovascular system other than the valve leaflets, annulus and a small contiguous portion of the aorta. It is generally conceded that the relative freedom from atherosclerosis in the supra-valvular portion of the aorta may be due to the protection afforded by the low pressure effected by the calcific aortic stenosis. Berk and Dinnerstein<sup>25</sup> on the basis of their study concluded that the etiology is still unknown but favored the possibility of a primary degeneration. Other findings which militate against the possibility of rheumatic etiology may be cited: the solitary occurrence of the lesion, that is, the absence of involvement of the mitral valve, the lack of appreciable thickening or shortening of the chordae tendineae, the massive deposits of calcium, and the absence of Aschoff bodies in the myocardium. Against arteriosclerosis, on the other hand, may be cited the absence of any marked sclerotic changes elsewhere in the body. Lesnick and Schlesinger<sup>11</sup> in a study of 39 cases of calcific aortic stenosis found 17 to have no associated mitral deformity and 22 to have an associated deformity of the mitral valve of rheumatic origin. They concluded that calcific aortic stenosis was not always rheumatic in origin, but thought that in some cases the underlying etiologic factor was probably of the nature of an arteriosclerotic degeneration. Clawson, Noble and Luffin<sup>12</sup> concluded from a study of 200 cases that calcific aortic stenosis was the commonest healed aortic lesion and that the change in the valve was due to repeated attacks of rheumatic proliferative inflammation with calcification similar to that commonly seen in mitral cusps.

The decision concerning the etiology must depend finally on thorough examination of the heart for the presence of rheumatic stigmas.

The hypothesis that calcific aortic stenosis represents the healed stage of subacute bacterial endocarditis usually fails to find corroboration in the absence of a history of prolonged febrile illness and in the lack at necropsy of healed embolic visceral lesions

#### INCIDENCE

Calcific aortic stenosis occurred<sup>17</sup> in 18 per cent of 6800 autopsied cases or 2.3 per cent of 4800 autopsied cardiovascular-disease cases

#### AGE AND SEX

The combined data of several investigators<sup>20 11 6 16</sup> showed 180 men (67.9 per cent) affected in a total of 265 cases. The same data revealed the greatest incidence in the middle and older age groups. In one series<sup>16</sup> the average age in 180 cases was fifty-two years and six months.

#### MORBID ANATOMY

Mönckeberg<sup>1</sup> believed that the anatomical alterations in calcific aortic stenosis were due to primary sclerocalcific changes. He regarded the process as originating in small atheromatous plaques situated in the sinus pockets, and believed that these plaques increased in extent and ascended toward the free border of the valve. He appreciated the necessity of differentiating the process from results of rheumatic fever, pointing out an important feature, namely, that the sclerotic and calcific process is largely present in the fibrosa layer of the aortic valve, whereas when it occurs as a secondary process in rheumatic fever it is confined chiefly to the ventricularis layer.

Willius<sup>18</sup> demonstrated that calcific aortic stenosis is usually limited to the cusps themselves. Variable amounts of calcareous material are deposited, primarily involving the aortic annulus, frequently one of the valve commissures and valve leaflets, although the free margin of the leaflets is involved chiefly when the process is very extensive. Fusion of the leaflets tends to occur, producing an adynamic valve which results in a barrier where stenosis predominates, but lesser degrees of aortic insufficiency may also be present. The calcareous process rarely involves the aorta itself except the immediately contiguous segment, and never involves the region where the coronary arteries originate. The left ventricle undergoes hypertrophy. An associated pericarditis is rare.

Sohval and Gross<sup>10</sup> made an extensive study of the anatomy of calcific sclerosis of the aortic valve (Mönckeberg type). They found

The valves are transformed into stiffened irregular nodular leaves with most of the thickening taking

place throughout the body of the leaflets rather than at the free edge. In advanced stages secondary sclerotic transformation produces extraordinary and bizarre deformities. Nodules vary in extent, extremely hard and rounded or sharply irregular, often penetrating through the ventricularis and auricularis enveloping layers of the cusp. Commissural agglutination may be sharp in milder forms and in advanced forms may be broadened, nodular and distorted, thus differing from the evenly rounded and broadened lesions often seen in subacute bacterial endocarditis, as well as from the delicate, grooved agglutinations found in the pure rheumatic process. The edges of the aortic leaflets in Mönckeberg's sclerosis may be sharp, or thickened and distorted, and do not usually present the rolled and inverted gross configurations characteristic of the rheumatic lesion. Histologically the earliest change is seen in the fibrosa layer near the base of the leaflet. Sclerotic and hyalin changes followed by lipoid changes occur. Next there is a deposition of calcific material. The nuclei in the fibrosa collagen tend to disappear. Capillarization of the aortic ring may occur if the process is close to the ring. In contrast to this the rheumatic calcified valve presents thickening and often vascularization of the spongiosa and ventricular layers in which calcification also occurs. Lesions of the valve ring are almost invariably present.

Sohval and Gross<sup>10</sup> believed that the pathogenesis of Mönckeberg's sclerosis was purely and primarily degenerative in character, showing practically none of the characteristics of rheumatic activity. They thought that the process probably depended on an individual predisposition to collagen involution and deposition of lipoid and calcium.

Berk and Dinnerstein<sup>26</sup> found involvement of the aortic ring, primarily at the roots of the valve. In the first stage only the outer layer at the site of the sinus of Valsalva was affected. Calcification then extended into the leaflets or one of the commissures, bulged into the sinuses of the valves, or formed radiating buckles within the valves themselves. Deposits of lime salts often filled the sinuses completely. The condition frequently progressed into the ventricles, producing spur-like formations under the endocardium. They found that calcification of the aortic valve might occur in combination with calcification of the annulus fibrosus or might be entirely isolated. The valves themselves were thickened, had an irregular surface and were fused at the commissures. The places of fusions often shrunk considerably and in so doing usually caused stenosis of the valves.

Margolis, Ziellensen and Barnes<sup>9</sup> found a tendency to hyalinization of the connective tissue with a deposition of lipoid material in the aortic valve ring and in the aortic valve with subsequent calcification. They believed that some cases had an inflammatory, others a degenerative basis. Ischemia, due to diminution of the vascular supply of the

affected tissues, seemed to be the basic pathogenic factor, producing hyalinization and other degenerative changes which subsequently proceed to calcification. The diminished blood supply might be due to narrowing or possibly obliteration of the arterioles of the aortic valve ring either as a part of generalized arteriosclerosis or as a selective and localized process, degenerative and calcareous deposits in the valves thus being produced.

Boas<sup>22</sup> alluded to the occasional extension of the fibrosis and calcification from the aortic ring to the annulus fibrosus and to the interventricular septum, with frequent impingement on and replacement of the atrioventricular bundle, such a change produced an anatomical basis for conduction defects in patients with calcific aortic stenosis.

### PHYSIOLOGY

Eyster, Meek and Hodges<sup>13</sup> found that experimental aortic stenosis and insufficiency in dogs were usually associated with a gradually developing cardiac hypertrophy. The heart with aortic insufficiency before hypertrophy developed failed to react as effectively to an overload as did the normal heart. There were no electrocardiographic changes characteristic of the early dilatation or hypertrophy subsequent to aortic lesions. Even extreme degrees of dilatation in the normal heart failed to cause significant changes in the electrocardiogram.

Katz, Ralli and Cheer<sup>14</sup> recorded the cardiodynamic changes in the aorta and left ventricle due to stenosis of the aorta by means of simultaneous pressure curves from the left ventricle and aorta. The disappearance of the similarity of the basic form of the two pressure curves during ejection when the aorta was stenosed arose from the fact that the two chambers were no longer in free communication while blood was being ejected. The faster and larger rise in ventricular pressure during ejection as compared with the slower and smaller rise in aortic pressure, was due to the decrease in the rate of conversion of potential mechanical energy in the ventricle to kinetic energy of flow. The lowering of the aortic pressure levels and the decrease in pulse pressure were due to the diminution in systolic discharge and minute output of the heart—obviously caused by utilization of more of the mechanical energy of the ventricle so as to overcome the added obstruction caused by the stenosis. In marked stenosis the effect of the increase in diastolic stretch may be large enough to counterbalance the primary effect of the aortic constriction and cause a temporary rise in pressure levels.

Green<sup>15</sup> found a decrease in coronary flow mainly

during systole in aortic stenosis, and believed that it caused a relatively high degree of systolic peripheral coronary resistance in relation to aortic pressure.

Boas<sup>22</sup> thought that when the aortic orifice was greatly narrowed, rapidly developing heart failure, by still further retarding the blood flow through the minute opening, might induce an acute myocardial ischemia analogous to that following coronary artery thrombosis and give rise to identical symptoms.

Harrison, quoted by Contratto and Levine,<sup>16</sup> believed that the angina might be due to relative anoxia. The work done by the heart demands more oxygen than the coronary blood flow can provide. The intraventricular pressure must be enormously increased because of aortic stenosis. The velocity factor, which under usual conditions has relatively little to do with cardiac work, may become the greatest factor in aortic stenosis, when with a markedly narrowed orifice the rate of flow must be enormously greater during systole. Angina may also be due to slight vasomotor changes in the caliber of the normal coronary vessels often found in cases of calcific aortic stenosis in young people. This may account for the less frequent relation of exercise to pain than in the ordinary coronary stenosis cases with angina pectoris. Contratto and Levine suggested a suction-pump action of the aortic blood stream with its increased velocity on the orifices of the coronary arteries which leave at right angles, this possibly diminishes the coronary blood flow and leads to a relative myocardial ischemia.

### DIAGNOSIS

#### *Symptoms*

The diagnosis of calcific aortic stenosis can only rarely be made on the basis of subjective findings. The heart is apparently able to compensate well for the change in dynamics caused by aortic stenosis. The relatively few subjective symptoms, coupled with general lack of awareness of this entity, have in the past led to errors in diagnosis of this form of valvular disease. In one series of 42 cases<sup>20</sup> only 6 had cardiac complaints. In another series of 236 cases<sup>17</sup> only a third were diagnosed *ante mortem*.

The chief complaints are usually those associated with angina pectoris, left ventricular failure (cardiac asthma), syncope, Adams-Stokes syndrome or congestive heart failure.

**Angina Pectoris** The symptoms of angina pectoris are found in a varying but considerable percentage of patients with calcific aortic stenosis. McGinn and White<sup>17</sup> reported that 19 per cent of 236 patients had angina pectoris. Margolis et al.<sup>9</sup>

reported 42 cases, 4 having angina pectoris. Contratto and Levine<sup>16</sup> reported 41, or 23 per cent, of 180 cases as having well-defined angina pectoris. Boas<sup>22</sup> reported 4 of his 19 cases as having classic angina pectoris. In all these cases a relative myocardial ischemia was the apparent cause.

**Left Ventricular Failure** Either a sudden or gradual failure of the left ventricle causes dyspnea, so-called "cardiac asthma," due to the diminished blood flow with congestion in the lungs. Although this manifestation is relatively rare, it should arouse suspicion of the presence of calcific aortic stenosis, particularly in the older age groups.

**Syncope and Sudden Death** Among the earliest cases of calcific aortic stenosis in the literature are found those with syncope and sudden death. Marvin and Sullivan<sup>26</sup> reviewed this literature, and pointed out that sudden death may occur in aortic stenosis as well as in the more widely recognized conditions of coronary thrombosis, anginal heart failure, atrioventricular block and syphilitic aortitis with aortic insufficiency. They believed the syncope to be due to overactive carotid-sinus reflex. This hypothesis does not find corroboration in the results of other investigators.<sup>16</sup>

**Adams-Stokes Syndrome** Typical Adams-Stokes attacks may occur in the course of calcific aortic stenosis. Their presence should be looked for when this diagnosis is under consideration. The attacks are apparently caused by the relative cerebral anemia due to the slow ventricular rate, or actual temporary cardiac asystole.

**Congestive Heart Failure** The slow progressive nature of the lesion in calcific aortic stenosis produces symptoms of congestive heart failure relatively late in the course of the disease.

## Signs

**Blood Pressure** A review of the data on blood-pressure readings reveals that when no complicating factors are present calcific aortic stenosis produces a systolic pressure which is likely to be low and a diastolic pressure which is apt to be slightly elevated, resulting in a small pulse pressure. Other factors which influence the height of the blood pressure are associated essential hypertension and, more often, aortic insufficiency. In 180 cases reported by Contratto and Levine<sup>16</sup> an average systolic pressure of 145 and diastolic pressure of 84 were noted. The range of the systolic pressures was from 260 to 80, while the diastolic pressures varied from 156 to 10.

**Pulse** The pulse is characteristically small, of a plateau type and not infrequently slow. It has been described as anacrotic or bisferious.

**Murmurs** There is a characteristic long, loud,

rough systolic murmur, either localized in the aortic area or, as often occurs, transmitted to the vessels of the neck. The diastolic murmur of a complicating aortic insufficiency is occasionally present. An Austin-Flint murmur may rarely be heard. In the interpretation of heart sounds it must be borne in mind that murmurs heard over the aortic or pulmonic areas do not necessarily arise from the corresponding valve.

**Second Aortic Sound** Owing to the adynamic aortic cusps found in calcific aortic stenosis, the second aortic sound is frequently of diminished intensity and may be entirely absent.

**Thrill** A systolic thrill over the aortic area is often found in calcific aortic stenosis. However, it is not consistently present and must not be insisted on before the diagnosis is made. In one series of 51 cases of aortic stenosis that came to necropsy a thrill had been found in only 21.<sup>17</sup>

**Enlargement of the Heart** As a result of the obstruction to the free passage of blood through the aortic orifice because of calcific aortic stenosis, it has been shown<sup>13</sup> both clinically and experimentally that the heart undergoes a gradual hypertrophy which is preceded by a stage of initial dilatation. In cases of long standing a markedly enlarged heart is the usual finding. Chevers<sup>29</sup> pointed out as long ago as 1842 that a morbid narrowing of the aortic orifice caused cardiac hypertrophy even in the presence of a completely obliterated pericardium.

**Electrocardiogram** Defects in conduction are commonly found in electrocardiograms. These include typical cases of bundle-branch block, increased P-R intervals and cases of complete heart block. Recently it has also been shown<sup>22</sup> that ischemia of the myocardium in calcific aortic stenosis, which may be further increased by a slow ventricular rate, produces electrocardiographic changes indistinguishable from those characterizing thrombosis of the coronary artery. Boas<sup>22</sup> pointed out an anatomical basis for conduction defects in cases with calcific aortic stenosis. Master, Jaffe and Dack<sup>30</sup> recently reported an electrocardiogram which could not be differentiated from that encountered in coronary thrombosis.

**X-ray and Fluoroscopy** Sosman and Wosika<sup>27</sup> reported 23 cases and concluded that roentgen ray visualization, roentgenoscopically and roentgenographically, of calcified heart valves during life was possible with present-day roentgen apparatus. With the proper technique<sup>25, 27</sup> the calcified valve can be seen to produce small dense shadows, rapidly moving or dancing up and down. They can not be projected outside the cardiac shadow and

are not affected by deep inspiration. It appears that they are best seen in the right oblique view in the median line, or a little to the right of it in the lowest third of the cardiac area.

### Course

The slow, progressive nature of the pathologic process similarly produces a prolonged clinical course. Symptoms do not appear until relatively late in the disease. When these have once made their appearance the subsequent course is usually brief. Thus, cardiac failure and often sudden death may be looked for. A life expectancy of about one year is the usual outlook when symptoms of congestive heart failure are noted.

### TREATMENT

The therapy of aortic stenosis prior to the advent of symptoms of congestive heart failure must be aimed at restricting the patient's activities and instituting a highly individualized regime in order to avoid unnecessary overwork of the heart.

When congestive heart failure makes its appearance it must be treated as failure due to any other type of lesion.

### CONCLUSIONS

Calcific aortic stenosis is becoming more and more often recognized. The possibility of its presence in an aortic lesion when no mitral lesion is present should be borne in mind.

The condition is not uncommonly followed by sudden death, and Adams-Stokes attacks may occur.

24 West 74th Street.

## REPORT ON MEDICAL PROGRESS

### THORACIC SURGERY

EDWARD D. CHURCHILL, M.D.\*

BOSTON

#### ANESTHESIA

**I**N THORACIC as in general surgery, there exists no unanimity regarding the choice of the anesthetic agent or the technic of administration. Local anesthesia for extensive operations on the chest wall or lungs has never been widely used in this country but remains the method of choice for the less extensive operations of drainage for empyema or lung abscess. Cyclopropane and oxygen has come into vogue in recent years, and in many clinics is considered indispensable for chest surgery. Certainly this mixture is preferable to nitrous oxide and oxygen because of its higher content of oxygen. However, the circulatory apparatus is under a severe strain in many chest operations, and the toxic effects of cyclopropane on the heart have not been tested by experience.

An ether vapor and oxygen mixture is, theoretically at least, even more ideal than cyclopropane in preventing anoxemia, as the oxygen content may be raised to almost 100 per cent. The reviewer has for several years been on the alert for any evidence that warm ether vapor mixed with oxygen and properly administered possesses irritating qualities deleterious to the lungs or air passages. It has been used as the anesthetic of election in hundreds of cases of thoracic disease, including acute tuberculosis. It has been compared with avertin, cyclopropane, barbiturate sedation and other agents singly and in combination. No evidence has been found that ether possesses undesirable qualities for use in chest cases, and unless special circumstances exist it is considered preferable to any other existing anesthetic. The prejudice against ether found its origin in the days of cone administration when patients were permitted to gurgle in their secretions in a state of sublethal asphyxia.

Experienced thoracic surgeons insist on differential-pressure anesthesia for operations in the free pleural cavity, although they are ready to admit that many patients will survive such an operation without it. Tracheal intubation has largely replaced the tightly fitting mask in the technic of administration. For differential pressure alone, a tube entering the larynx via the nose is sufficient, if purulent secretions are plentiful, as in bronchiec-

tasis, a large Flagg tube is employed so that aspiration can be carried on. In some clinics (Rienhoff, Ochsner) intubation of the trachea is avoided on the ground that infection may be introduced.

#### BRONCHOGRAPHY

Roentgen-ray demonstration of the bronchial tree by the injection of opaque solutions into the respiratory tract is an established and exceedingly valuable procedure. If carefully done by an expert untoward results are rarely encountered. The value of the demonstrations as a preoperative study for the visualization of pathologic lesions transcends its use in pure diagnosis.

The use of bronchography should not be considered comparable to that of contrast mediums in the study of the gastrointestinal tract. In general it requires a more exacting technic, and if used incorrectly the oil may be retained in the parenchyma of the lung and obscure later pathologic developments.

The chief use of bronchography has been found in bronchiectasis, where the pattern of the disease may be completely outlined and the feasibility of surgery determined. It is rarely employed in lung abscess, tumors of the lung or pulmonary tuberculosis. It should never be used routinely as a method of studying an unselected group of patients with thoracic disease.

Many methods of injection have been elaborated. Catheterization of the trachea through the cannalized larynx seems to afford the most precise control of the distribution of oil and the best control of the position of the patient for accompanying roentgen ray studies. For detailed problems a special catheter may be inserted into individual bronchial segments and a record made by spot films under fluoroscopic guidance (Thompson, Goldman and Adams).

Bronchography by the injection of oil with the bronchoscope in place tends to give disappointing results. If it seems necessary to combine the two procedures, injection of oil should be done after the bronchoscope is withdrawn and the cough reflex has subsided.

The roentgenographic technic of bronchography must be systematic and thorough. A unilateral injection is first made and recorded by anteroposterior and lateral films. Following injection of the sec-

\*John Homans, Professor of Surgery, Harvard University, chief of West Surgical Service, Massachusetts General Hospital.

ond side, anteroposterior and oblique films are required. A great majority of the records made by those unexperienced in the procedure are worthless, as they yield only incomplete evidence and require repetition in the hands of an expert team.

#### BRONCHOSCOPY

The bronchoscope is as important in the diagnosis of chest disease as the proctoscope is in the study of the large bowel and rectum. In expert hands it is usually no more disturbing to the patient. In interpreting the findings of a bronchoscopy, however, the instrument's range of vision must be kept clearly in mind. This is limited essentially to the orifices of the first subdivisions of the lobar bronchi. With the aid of the fluoroscopic table foreign bodies may be recovered from more remote regions of the lung. The aspirating cannula may be inserted into the fine subdivisions. Visualization of pathologic lesions, however, and precise biopsies are possible only in the limited area designated.

Precision in the use of the bronchoscope is furthered by a complete preliminary study of the case. Exploratory bronchoscopy should be as unusual an event as exploratory laparotomy. Adequate fluoroscopic and roentgen-ray study usually results in requesting the bronchoscopist "to take a biopsy from the mass presenting in the first dorsal division of the left lower lobe bronchus" rather than merely asking him what he can see.

Barring the extraction of foreign bodies, the therapeutic potentialities of the bronchoscope are not so impressive as is its value in diagnosis. Its efficacy in the treatment of acute lung abscess is still questioned outside Philadelphia. The results in bronchiectasis are palliative, and only occasionally better than those attained with postural drainage. As an intensive preoperative measure the procedure may be helpful in building up the general condition of the patient. Small benign tumors may be removed successfully by the bronchoscopist, and areas of lung drowned in retained bronchial secretions drained by removing the obstruction due to larger tumors. Cicatricial stenosis may be dilated in some cases, with relief of symptoms.

The significance of a negative bronchoscopy in primary carcinoma of the lung depends entirely on the location of the tumor. Failure to obtain a positive biopsy when obstruction to a lobar bronchus has been demonstrated by x-ray is important evidence against carcinoma. Failure to reach a peripheral tumor is to be expected, and in fact, under these circumstances, bronchoscopy may not be advised.

The location of an area of suppuration may be designated by observing pus exuding from a bron-

chial orifice. The source of a positive tuberculous sputum may be determined if aspirated secretion from one lung is constantly negative and that from the opposite lung positive.

The clinical importance of tracheobronchial lesions has led to a more frequent use of the bronchoscope in tuberculosis. The ulcerative and stenosing lesions of this complication have an important bearing on the results of and the indications for collapse therapy.

#### EMPHYEMA

During the influenza epidemic of 1918, high-pressure publicity was given to the intercostal-catheter method of drainage for acute empyema. In succeeding years the method was modified and amplified by an untold number of devices for the maintenance of negative pressure and the flow of irrigating solutions. As more emphasis has been placed on the principles of the treatment of empyema rather than on the details (Heuer, Graham), the enthusiasm for the rediscovery of complicated methods has calmed down.

The catheter method of intercostal drainage is a lifesaving measure under certain circumstances, it is also a very effective form of treatment for a large number of cases in infancy and childhood. In general, however, it is more difficult to carry out and leads to more complications in inexperienced hands than does needle aspiration, followed by rib resection when the pus has thickened. The important principle to bear in mind is not to create a pneumothorax by any method in a patient who has a reduced respiratory reserve. Early in the 1918 influenza epidemic this was done by resecting a rib during the acute phase of streptococcal bronchopneumonia, and disaster naturally followed.

In the community at large there seems to be more difficulty arising from taking out the drainage tubes prematurely than from putting them in. In this regard it is emphasized that a tube should not be removed until the cavity has become obliterated. The most effective calibration of an empyema cavity is made by the injection of Lipiodol under fluoroscopic guidance.

Specific immunological measures may well lessen the incidence of empyema both in streptococcal and pneumococcal infections. There are already encouraging signs pointing in this direction.

#### LUNG ABSCESS

Putrid lung abscess remains one of the most destructive forms of thoracic disease and one of the most difficult therapeutic problems. A wave of animal experimentation seeking to throw light

on the pathogenesis of the disease swept over the country a few years ago. This has now subsided, leaving the conclusion that abscesses can be produced either by infected vascular emboli or by infection via the bronchial route. The majority of clinicians hold to the aspiration theory.

Because of the fact that approximately 20 per cent of all cases may be expected to heal spontaneously, there is still a tendency to prolong the period of expectant treatment to an illogical degree. Neuhof has recently been a strenuous advocate of "early operation." As a warning against dangerous delay his advice is sound. It has long been known that spontaneous healing rarely occurs unless definite signs of regression are observed during the first six weeks. Many surgeons still believe that at least this period should elapse in a majority of cases before operation is performed. This pause serves not only to allow spontaneous healing to take place but to permit subsidence of the concomitant pneumonitis. It is not clear from Neuhof's writings whether operation at the end of six weeks falls within his definition of "early."

Neuhof has also urged operation in one stage. The safety of this procedure is questioned by a number of surgeons experienced in the field, and he stands almost alone in making this recommendation. Aside from the dangers of contaminating the pleural space, a great deal is gained by the protection against infection of the chest wall which is afforded by the two-stage procedure.

Drainage of an abscess by no means ends the story in many cases. Sequestration of the lung commonly results in a defect that resists the processes of natural healing. In a few borderline cases the defect may be closed by turning a pedicle muscle graft into the cavity. The healing of residual apical cavities may be aided by thoracoplasty. It is becoming increasingly clear that the large defects must be treated by lobectomy or pneumonectomy if permanent healing is to be expected.

Certain cases of lung abscess in the subacute or chronic stage (two months and longer) present indications for primary lobectomy. A consideration of this method is particularly recommended in abscesses of the upper lobe, as they are notoriously difficult to drain adequately and are resistant in healing.

The Philadelphia group continues to report favorable results in the treatment of lung abscess by bronchoscopic aspiration. Success appears to depend on instituting treatment very early after onset. If improvement is not soon manifest or if the abscess recurs after a remission, recourse is had to surgical drainage.

A good deal of the confusion that exists re-

garding the therapy of lung abscess may be traced to variations in the clinical material of various institutions. An enthusiastic report (Nammack and Tiber) regarding the efficacy of guaiacol recently emanated from Bellevue Hospital. Careful study of the individual case reports shows that a predominant number of cases were what might be classified in other hospitals as septic pneumonitis from the aspiration of pharyngeal secretions or gastric contents during an alcoholic debauch. These cases are common in large municipal hospitals receiving admissions from the police ambulance service. Their clinical course is quite different from that of the putrid post-tonsillectomy abscess.

As a preventive measure, tonsillectomy and other operations in the nasopharyngeal region must be regarded as serious affairs, particularly in the adult patient. In elective procedures, oral hygienic measures should be undertaken as a preliminary step. Every effort should be made to minimize the extent of denuded areas that must heal by granulation attended by suppuration.

#### PULMONARY TUBERCULOSIS

The consultation services of a thoracic surgeon are now indispensable in any institution housing patients with pulmonary tuberculosis. Certain states (Connecticut and New York) have developed comprehensive programs that combine their several institutions in a unified surgical service. In Massachusetts the two state institutions are served by one consultant, and the eight county sanatoriums by at least four other consultants experienced in chest surgery.

Extrapleural thoracoplasty has become increasingly effective as the technic of its performance has been perfected. The principle of extrafascial apicolysis introduced by Semb, of Oslo, has been accepted in most clinics and is used as a routine adjunct to the removal of ribs. This procedure drops the apex of the pleura to the level of the fifth rib. Combined with the resection of long segments of the upper ribs, extrafascial apicolysis is so effective that thoracoplasty for upper lobe disease is rarely carried below the seventh rib.

A revival of extrapleural pneumothorax is well on its way. When intrapleural pneumothorax is impossible because of adhesions, the parietal pleura may be stripped from the chest wall and the space so created maintained by refills of air. It seems wise at the present to reserve this procedure for use in patients in whom thoracoplasty is certainly contraindicated. While very ill patients withstand the operation surprisingly well, it should not be considered a substitute for thoracoplasty on the grounds that it is a less disturbing procedure. In many cases thoracoplasty to close the space will

have to be performed at a later date, and when the mortality of late complications is included, it may be safely predicted that the risk of the procedure will be found greatly to exceed that of thoracoplasty. There are certain cases, however, in which it is being carried out as the only possible effective measure.

Phrenic nerve surgery has suffered a recession in popularity, at least east of the Hudson River. Permanent paralysis of the nerve is rarely performed, and temporary paralysis is carried out with far less frequency than a few years ago. The procedure has been found to be relatively ineffective, and what is more important, actually to increase the risk of a subsequent thoracoplasty. There are still distinct indications, however, for its use in carefully selected cases.

Bilateral thoracoplasty has on the whole been found disappointing. The removal of sufficient ribs to arrest the disease effectively is apt to leave the patient a respiratory cripple.

The goal of collapse therapy is a negative sputum, and laboratories have met this challenge by refinements in sputum examination extending through concentration methods to cultures and guinea-pig inoculations. Examination of the gastric contents is the final step when the patient no longer raises sputum. While these efforts are laudable and increase the understanding of the disease, it is difficult at the moment to know what they mean from a practical prognostic standpoint. Certainly many cases formerly classified as arrested by any form of treatment would now be found to be carriers of the tubercle bacillus.

#### BRONCHIECTASIS

Extirpation of the diseased areas of lung has long been the goal of those familiar with the pathology of bronchiectasis. Early efforts in lobectomy were attended with an operative mortality rate that was prohibitive. Attempts were then made to find a substitute, and collapse therapy by pneumothorax or thoracoplasty (Hedblom), cauterly pneumonectomy (Graham), and exteriorization lobectomy (Whittemore) had their day. In 1926, Brunn revived the direct surgical attack. Shortly thereafter Shenstone devised the ingenious snare tourniquet that simplified the technical problems of dealing with the hilar stump. The development of bronchography made it possible to outline the pattern of the disease so that a systematic surgical program could be planned. The net result of these and other aids to diagnosis and technics has been a reduction in the operative risk of lobectomy from 50 per cent to less than 5 per cent. Surgery is now routinely recommended even in the milder cases of the disease.

An area of lung which is the site of established

bronchiectasis must be regarded as irreparably damaged. No evidence exists that the pathologic lesion is a reversible one. The symptoms are notoriously variable in the same individual at different seasons of the year or at different periods in the course of the disease. In general, the initial insult to the lung structure occurs early in life and is of varied origin. The basic element in the pathology is a destruction of the ability of an area of the bronchial tree to rid itself of the secretions of the mucous membrane. The dilatations may remain "dry" and cause no symptoms for periods of years. Sooner or later, however, infection occurs and cough and sputum manifest themselves. Infection, favored by stagnation, leads to the characteristic odor from decomposing secretions. Hemorrhages result from ulcerations of the bronchial mucosa, and are infrequent when long-standing infection has erected a barrier of peribronchial fibrous tissue. In fact, hemoptysis is more apt to occur in the "dry" phase of the disease.

Established infection increases the tendency toward stagnation of secretions by hypertrophic changes of the mucous membrane. Acute episodes of pneumonitis spreading from the focus of the disease recur with increasing frequency. Pleurisy and empyema appear as complications. The accessory nasal sinuses quite commonly become infected and serve as an additional focus for the perpetuation of an endless series of respiratory tract infections, particularly during the winter months.

The progressive course of the symptoms has led to the conception that bronchiectasis is a progressive infection of the lung. As a matter of fact, the anatomic pattern of the disease is usually complete at the time the diagnosis is first made. Patients may progress to advanced stages of the disease with the production of a copious volume of malodorous sputum and still show a sharply localized lesion in one lobe or even a single portion of a lobe. Involvement of other areas of lung does occur, but usually as the result of an episode of acute infection. Other areas of lung become damaged by fibrosis and emphysema as a sequel to focal areas of pneumonitis or bronchitis.

A concept of the underlying pathology of the disease is essential to an understanding of its treatment. Conservative measures such as postural drainage, bronchoscopic drainage, local treatment of nasal sinusitis, vaccines, change of climate and sanatorium regimen may be classified as symptomatic treatment. Certain of these measures are to be employed when contraindication to operation is present, or may be useful to prepare the patient for operation. Curative treatment resides only in surgical extirpation of the diseased area of lung.

Certain bilateral cases have been made the sub-

jects of bilateral lobectomy. These cases require careful selection and accurate appraisal of the lung tissue that is to remain. They will always constitute a small group so far as surgery is concerned.

While the ideal case for operation presents a localization of the disease to a single lobe, technical methods are being developed to deal with foci of bronchiectasis scattered throughout several lobes. In cases coming to operation before the dense scarring of chronic infection offers a barrier, segmental resection of diseased areas with conservation of normal lung substance may be possible (Churchill).

Cases of bronchiectasis or cystic disease involving an entire lung may be cured by total pneumonectomy. In the presence of active infection this becomes one of the most formidable operations of thoracic surgery and carries a correspondingly high risk, approximately 35 per cent. The chief hazard lies in uncontrolled hemorrhage from the vascular adhesions that fuse the lung with the chest wall. A second hazard lies in the post-operative infection of the pleural space, mediastinum and chest wall. Amputation of the hilus usually requires use of the tourniquet technic rather than individual ligation of the vessels as in primary carcinoma.

The appraisal of the possibilities of surgery in bronchiectasis centers about a precisely done and complete bronchogram. Disappointing results will follow a failure to delineate completely the pattern of the disease before embarking on a surgical program.

#### PRIMARY TUMORS OF THE LUNG

The most outstanding achievement in the field of chest disease during the past decade has been the extension of knowledge concerning primary tumors of the lung. Internists, radiologists, surgeons and pathologists have found the subject a productive field for their best efforts, and the accumulated literature has assumed vast proportions.

The most spectacular operation of thoracic surgery—total pneumonectomy—has emerged as the answer of the surgeon to the challenge of hopeless malignant disease. It is now a little more than five years since the first successful removal of an entire lung for epidermoid carcinoma (Graham). Although the vast majority of cases reach the surgeon at a time when the possibility of arresting the disease by extirpation has passed, sufficient experience has been accumulated to demonstrate the feasibility of the procedure from a technical standpoint.

The operative risk of total pneumonectomy is high. Statistics dealing with operative mortality

are at the present time so colored by variations in the criteria of operability, as well as variations in the technics employed, that an estimate, if given conservatively, is of more significance than a thorough analysis of reported cases. As a conservative estimate, it may be stated that the hospital mortality for total pneumonectomy in the absence of a preoperative element of infection is leveling off at about 20 per cent, with infection, at between 35 and 50 per cent.

Statistical evidence regarding the frequency with which the surgeon is able to arrest carcinoma of the lung will not be available for many years. Certainly there is no reason to believe that surgery will be more or less efficacious in dealing with pulmonary carcinoma than it has been, it might be said, with carcinoma of the stomach. While enthusiasm is being centered about patients surviving the operation, it must not be forgotten that the operation is being undertaken for cancer.

Total pneumonectomy may be carried out by individual ligation of the vessels and careful suture of the main bronchus unless an inflammatory barrier makes dissection within the mediastinum impossible. In the latter event, tourniquet amputation becomes necessary. In the absence of gross contamination from an infected lung (pneumonitis, obstructive endobronchial suppuration and even actual abscess formation are frequent concomitants of pulmonary neoplasms), the pleural cavity may be closed without drainage and healing by first intention secured. If infection of the pleural space ensues, drainage is employed and a thoracoplasty to obliterate the unilateral empyema cavity performed at a later date.

The pendulum has swung to the extreme point of view in regard to total pneumonectomy as the only operation for primary carcinoma of the lung. It is the ideal operation in the sense that it offers a more complete eradication of the primary growth and adjacent lymph nodes than any more limited procedure. It will be required in a majority of cases by reason of the anatomic site of the primary growth. It is not the ideal operation, however, if patients without lymph-node involvement are going to be sacrificed because of the high operative risk that it entails. The prospects of cure of any cancer are relatively so poor, once regional metastases have taken place, that an effort routinely to extirpate regional lymph nodes at a high price in operative mortality seems of doubtful wisdom. For this reason, lobectomy, if the primary growth and any demonstrably involved lymph nodes can be removed thereby, should still find a place in the treatment of lung tumors.

A positive preoperative diagnosis materially

strengthens the hand of the surgeon in assuming such a serious responsibility. This may be obtained by bronchoscopic biopsy in approximately 70 per cent of all cases, but in a smaller percentage of the operable group. The latter will include a relatively large number of peripheral tumors that cannot be reached with the bronchoscope. In many cases, therefore, operation must be advised and carried out in the absence of a preliminary microscopic diagnosis. Expert roentgen-ray technic and interpretation is essential under these circumstances.

A primary tumor arising in the bronchial wall and superficially resembling bronchogenic carcinoma has been variously referred to as "benign adenoma" or "carcinoid." Whatever the histogenesis and nature of this tumor are ultimately proved to be, clinically and prognostically it differs sharply from carcinoma. Invasion is extremely slow and limited in extent, and metastasis is extraordinarily rare. Many such tumors, however, require radical extirpation because of the damage done to the lung by long-standing bronchial obstruction and infection.

Unfortunately, these tumors are still being confused with cancer, and inclusion of them in end-result studies gives a distorted picture of both operative mortality and ultimate survival. These tumors are observed with a frequency of 1 to 10 true carcinomas. Of the group of resectable bronchogenic tumors, however, they comprise 25 per cent in the Massachusetts General Hospital series (8 adenomas to 24 resectable primary bronchogenic carcinomas).

Whether or not this tumor is potentially malignant, its inclusion in statistics purporting to deal with cancer will give rise to undue optimism in the interpretation of results. If for no other reason, the adoption of the classification suggested by Womack and Graham must be accepted with caution.

#### HEART AND GREAT VESSELS

The most spectacular achievement of the decade in the surgery of the heart and great vessels has been the successful closure of a patent ductus arteriosus in 4 cases by Gross. Without detracting from the brilliant achievement of the surgeon, our compliments must be extended to the internist, Hubbard, who had courage to recommend the operation to his patient. Many of the "firsts" in surgery await the conjunction of an internist with imagination, a surgeon with courage and skill and, last but not least, a willing patient.

Attempts to provide an artificially produced collateral circulation to the myocardium in cases of insufficient coronary circulation have been made

by Beck in this country and O'Shaughnessy in London. Beck has utilized the muscles of the anterior chest wall, and O'Shaughnessy the omentum fixed in contact with the surface of the heart. Painstaking experimental observations on animals have served as a basis for the clinical experiment. Encouraging results are claimed by both workers.

Successful suture of wounds of the heart is now commonplace in the South. Elkin of Atlanta and Bigger of Richmond have materially added to the clinical diagnosis and operative technics of cardiac suture.

Decortication of the heart for constrictive pericarditis (Pick's disease) has become firmly established as a therapeutic procedure. Additional light on the disturbed mechanics of the circulation has been provided by the observations of Burwell and his co-workers on cardiac output before and after operation. White believes that the syndrome is rarely if ever of rheumatic origin. Tuberculosis seems the most probable etiology in a majority of cases but can rarely be proved by direct evidence.

#### ESOPHAGUS

The time is ripe for a more determined surgical attack on carcinoma of the esophagus. Irradiation has been shown to destroy the tumor in certain cases, but leaves a legacy of fibrosis which perpetuates the obstruction. Sporadic success with surgical extirpation has been reported over a period of years, but many technical problems require a more extensive experience for their solution. In an early case surgery should be considered the procedure of choice.

Perforation of the cervical esophagus has been labeled a surgical emergency by Pearse. He recommends immediate exteriorization of the perforation by a cervical incision and packing. Mediastinotomy, he says, may be advisable in perforations below the fourth thoracic vertebra.

A controversy still rages between the proponents of a two-stage and a single-stage operation for the common pharyngeal or pulsion diverticulum. Lahey favors the two-stage procedure, whereas Shallow reports a large series of cases done by the single-stage method. There is no generally accepted answer at present.

#### MEDIASTINUM

The mediastinum has established a reputation as the domicile of large rounded tumors which stimulate a guessing game in preoperative diagnosis. In general, the neurogenic tumors neurofibroma and ganglioneuroma, tend to be situated posteriorly, and the teratomas and dermoid cysts anteriorly.

Intensive irradiation of these tumors in the absence of a definite diagnosis is to be heartily condemned. In certain cases it may be advisable to give a "lymphoma" dosage as a diagnostic measure. If the tumor regresses it is obviously not one that should be treated surgically, if it does not respond to light irradiation, surgical exploration to determine its nature and remove it if possible is indicated. Excellent results are obtainable in the group of benign tumors and cysts.

#### DIAPHRAGM

The thoracic approach is commonly recommended for the repair of rupture of the diaphragm—a not infrequent result of severe trauma. Rupture of the diaphragm with displacement of abdominal viscera into the pleural cavity is to be differentiated from hernia through an anatomic hiatus. Hernia through the esophageal hiatus is observed quite commonly by radiologists, but only rarely can be fixed on as the cause of symptoms. This lesion may be repaired by the abdominal approach. Harrington has presented a carefully considered anatomic repair of this defect and cites his experience with a large series of cases. Surgical repair of eventration of the diaphragm has not been reported, and presents a difficult problem.

TRACY B. MALLORY, M.D., *Editor*

## CASE 25241

## PRESENTATION OF CASE

*First Admission* A sixteen-year-old girl was admitted complaining of pain in the right knee.

For the past four months she had had a dull aching pain in the right knee made worse on walking. During the last two months she had been unable to flex or extend completely the knee. There was no pain at night if she lay on her back holding the right knee sideways, lying on her face caused pain. The knee gradually became swollen, more so at night. The pain and swelling slowly became worse, and one month before admission it became constant. During the previous two months the right ankle became slightly swollen and painful at night. There was no history of injury, locking, inflammation, fever, night sweats or pain elsewhere. Her past and family histories were noncontributory.

Physical examination showed a well-developed and nourished girl in no acute distress. Examination of the heart revealed a loud blowing systolic murmur loudest over the pulmonary area. The blood pressure was 140 systolic, 85 diastolic. The patient walked with a limp, holding the right knee at about 20° of flexion. The right knee was somewhat swollen, and the right leg above the knee was slightly wasted. Moderate tenderness was present over a somewhat firm swelling along the anterior edge of the tibia just below the patella.

The temperature was 98.6°F., the pulse 80, and the respirations 20.

Examination of the urine was negative. The blood showed a red-cell count of 5,000,000 with 80 per cent hemoglobin, and a white-cell count of 14,400 with 68 per cent polymorphonuclears. A blood Hinton test was negative. Tuberculin tests in dilutions of 1:5000 and 1:1000 were negative. The blood serum calcium was 10.93 mg per 100 cc., the phosphorus 4.64 mg, and the phosphatase 2.86 Bodansky units.

X-ray films showed a large area of diminished density involving the central portion of the head of the right tibia. There was marked thinning of the cortex, the process extending to the articular cartilage. The area was trabeculated. The lower border was somewhat irregular. There was very little evidence of expansion, the cortex being in-

tact. The lower femur showed some diminished radiance probably due to atrophy. Films of numerous other bones showed no evidence of disease. The chest was negative.

On the eighth hospital day operation showed a typical giant-cell tumor which was shelled out, and the cavity curetted. The upper end of the normal shaft of the tibia was then chiseled obliquely and the cavity filled with periosteum and soft parts. A tongue-shaped flap of periosteum was allowed to drop back into the cavity. The pathological report on the tumor was benign giant-cell tumor. The patient rapidly recovered and was discharged on the twenty-ninth hospital day.

*Second Admission* (four years later) Following discharge the patient remained perfectly well until eight weeks before re-admission when, without trauma or other known exciting cause, she began having dull intermittent pain in and just below the right knee. It gradually became more or less continuous, especially at night. Three or four weeks before entry the pain became so severe that she was forced to give up her work in a shoe factory. She began using a cane. The knee then began to assume a permanently flexed position. Swelling then occurred in the region of the old operative incision and increased until it involved the entire lower leg when the leg was kept in a dependent position. The pain then became quite localized to the area beneath the operative incision. The appearance of the skin did not change. During the previous two weeks she had used crutches. There was no pain elsewhere, and no fever or malaise. She had lost about five pounds in weight in the past three months.

Physical examination was negative except for the right leg. Over the medial aspect of the proximal end of the right tibia there was a dome-shaped mass 7 cm in diameter and 2 to 3 cm high, which felt tense and slightly fluctuant in its midportion. There was a healed scar overlying it. It was apparently fixed to the underlying structures and to the tibia. The skin surface was possibly slightly warmer than that of the opposite leg. The mass was slightly tender throughout, but especially so in the anterior portion. There was no evidence of increased fluid in the joint. The inguinal lymph nodes were not enlarged. The right calf and thigh showed evidence of atrophy.

The temperature was 97.8°F., the pulse 88, and the respirations 20.

The urine examination was negative. The blood showed a red-cell count of 5,600,000, and a white-cell count of 10,720 with 84 per cent polymorphonuclears. A blood Hinton test was negative. The serum calcium was 10.77 mg per 100 cc., the phosphorus 3.6 mg, and the phosphatase 4.24 units.

X-ray films showed an area of diminished density in the extreme upper end of the right tibia with rather ill-defined margins and measuring 4 cm in diameter. In the central portion of this area the trabeculae were increased in density and were rather mottled in appearance. The bone surrounding the area was dense and sclerotic. There had been a considerable amount of new-bone formation in the operative area medially. There was slight tilting of the joint surface of the tibia toward the medial side.

On the fourth hospital day an operation was performed.

#### DIFFERENTIAL DIAGNOSIS

DR CHARLES C LUND \* This is the type of case where the x-ray is of special importance in making a diagnosis. I wonder if we could see the films now.

DR TRACY B MALLORY The x-rays on the first admission are not available. They have been sent to the Bone Registry, but no one who has seen them questions the statement that the picture is entirely typical of a benign giant-cell tumor. Dr Schatzki will show you the subsequent films.

DR RICHARD SCHATZKI The first film is a post-operative film and shows the location of the lesion and the postoperative defect.

DR LUND At the first admission?

DR SCHATZKI Yes, in 1934.

DR LUND The triangular-shaped defect is at the upper end of the tibia on the medial side and measures about 5 by 5 by 5 cm. It leaves a lateral margin of the tibia that is a little bit wider than the fibula.

DR SCHATZKI Four years later there is marked regeneration of bone in the area of operation. A cavity-like defect is seen in the midportion of the condyles of the tibia which apparently was present at operation and represents the area of the original tumor. The appearance of this cavity has, however, changed. There are small cup-like areas of new-bone formation in this region. The soft-tissue mass described in the report extends over the upper edge of the cavity along the medial aspect of the tibia and shows nothing but a homogeneous soft-tissue shadow.

DR LUND Going now to the postoperative film there is complete removal of this triangular area of bone. Looking closely in connection with what has developed since, one sees that the epiphyseal region is denser than the area on the other side and does not look as though there had been complete removal of any process that may have been there. It looks to me as if there possibly had been only partial removal of diseased bone in that

part, but of course I cannot be sure of that. In the recent film one sees filling in this area of increased radiance, an irregular area of increased density, and in addition a definite soft-part tumor medially, with a little break in the somewhat irregular contour of the healed bone.

In the early part of this century, I think probably largely due to some of Dr E. A. Codman's work, a clear distinction between the various primary tumors of the bone began to be made and people started to realize what had not been appreciated in the latter part of the last century, namely, that the group of bone tumors with foreign-body giant cells scattered through the tumor tissue were not in any way like the osteogenic type of tumor. A great many amputations had been done in the past for cases that were not very malignant. When I was a student and intern—which is now going on to twenty years ago—we were taught that the giant-cell tumor was not malignant. But shortly after that, due to further work by Dr Codman and particularly presented in a paper by Dr Simmons,<sup>1</sup> that was shown to be untrue. There are cases of giant-cell tumor that without changing their pathologic character have the ability to metastasize and there are cases of apparently very definite giant-cell tumor that shift over into what may be called osteogenic tumors. With that background we have to consider whether in this case the process that was present on re-entry was a recurrence of a giant-cell tumor, whether it was a development of an osteogenic type of tumor in the presence of what was originally a giant-cell tumor, or whether it was something else entirely different. This soft-part tumor bothers me a great deal because I should not expect a mass of that size with no calcification in connection with either of the two types of process that I have just described. Moreover this was described as a semi-fluctuant mass, which makes one think of infection. There is no other evidence pointing in that direction, however. The temperature was not raised, and the white-blood-cell count not elevated, and a remote infection at this late date, four years after operation, can be quite well ruled out. Finally, I think it would be unreasonable to consider here any process totally unconnected with the original one, such as metastatic malignancy or a new disease.

Just a word more and then I shall make an attempt at a diagnosis. Of course the clinical diagnosis here is highly unimportant. This is one of the cases where the surgeon rightly puts all the responsibility on the pathologist. One should not decide on the x-ray and clinical evidence what type of surgery was indicated. All one should decide is that a biopsy was indicated, and

\*Assistant professor of surgery Harvard Medical School visiting sur

then following the opinion of the pathologist one should be ready to go ahead with some kind of surgery, either a local removal or an amputation. It would be very difficult to plan any local removal of this process that would result in a useful leg. One might think of x-ray treatment, but such a decision depends on the diagnosis. There is one other bit of evidence to be considered—the chemical data. If she had a high blood phosphatase one would think that the tumor had probably shifted to an osteogenic type of malignancy in place of the giant-cell tumor. This particular phosphatase is not high enough to mean much.

For my first choice I am going to say that this process is a recurrent giant-cell tumor, and for my second choice, an unusual osteogenic sarcoma.

DR ERNEST A. CODMAN. This case was of unusual interest to me, not only because the patient was a very brave girl, but because there were a good many features in the case that were very instructive. Dr Lund, calling attention to the x-ray taken after the operation, assumed that the removal of the tumor had been incomplete. The fact is that the whole tumor was shelled out from beneath the joint cartilage and from the bony walls of the head of the tibia. Moreover the inner walls were smooth, and there was no gross evidence of invasion by the tumor. Dr Lund was deceived by this film because the posterior wall of the cavity remains intact, but the tumor was completely removed and a wedge-shaped flap of periosteum turned into the cavity with the express idea of having it develop on the line of stress according to Wolff's law, to form new structural bone. She did obtain good use of the leg, many of you saw her two years ago at the meeting we had on giant-cell tumors. She had perfect function and almost perfect contour for four years. Then suddenly, in November, 1938, acute pain began and was soon followed by swelling. She had had good function for four years. When she entered the hospital, the tumor was fluctuant, so that I hoped that it was an abscess, due possibly to a sequestrum, but when I explored I found a very malignant almost purely cellular tumor with no giant cells in it, it was quite different histologically from the original one. There were many mitoses.

She refused amputation at first but two weeks later we persuaded her to have it done, and Dr Van Gorder removed the leg. She went home and almost immediately developed metastases in the lungs and died. The duration from the development of signs of recurrence to death was only four months, and yet for four years after operation there had been no trouble.

To me one of the most interesting facts to record

is that at this operation I made the incision in the bone well below the tumor for the express purpose of finding what we call a concavoconvex line in the marrow. A giant-cell tumor always has a visible sharp concavoconvex line separating the marrow from the tumor tissue. In cases of osteogenic sarcoma there is always an irregular extension up into the medulla above the obvious tumor, that is, the tumor extends up in the medulla higher than the x-ray shows it. In giant-cell tumors, the x-ray shows this concavoconvex line. I made my periosteal flap starting about 5 cm below the tumor and took away the cortex in order to look at this line to see whether it was typical of giant-cell tumor. In the past I have taken every opportunity I could to examine the medullary invasion in different forms of tumor at the medical school museum and in registered cases. I find it almost an invariable rule that the concavoconvex line is present in giant-cell tumor. In the paper I wrote about this case<sup>2</sup> I made the statement that I believed that the surgeon should decide for himself, on finding that line, that it is one of a giant-cell tumor and go ahead and treat it as such. That line was present in this case and was perfectly typical.

Then another point, the gross appearance was characteristic. The surgeon knows the "currant jelly" appearance of this kind of tumor. Moreover, another gross sign was present. It shelled out easily, as it always does in giant-cell tumors, and very little was left on the edges or on the clean wall inside. Still another point in the gross appearance was its extension to and limitation by the joint cartilage. Of course the x-ray film is a little deceptive because the posterior wall was still present, but the whole thing was cleaned out. There were, however, little irregularities in the smooth walls where cells might have stayed. I purposely did not use a chemical cautery to remove such cells as might have been there, because I felt that they were probably giant-cell tumor cells and were of little danger.

Now, could such a malignant type of cell as we found at the second operation have been there for four years, together with the gradually developing new bone? The patient walked around perfectly freely without pain. If it was a malignant tumor in the beginning it took a long time to recur. Its rapid growth, when it appeared the second time, suggests a new tumor. This case was registered and went the rounds, all the men on the registry committee wrote "giant-cell tumor" on the specimens—as I think they would today. I believe that this is a very critical case in showing that surgeons and pathologists together cannot tell a giant-cell tumor every time. Dr Simmons several years ago pointed out that 7.5

per cent of supposed giant-cell tumors later developed into real malignant tumors. Recently when I went over the tumors of the knee joint I found almost exactly the same percentage. I think this is a minimum rather than a maximum figure, because I have found so many cases, in this community, where supposed giant-cell tumors later showed malignant changes. For instance, there was a case at this hospital which Dr. S. M. Roberts operated on and filled with bone chips. Dr. A. R. MacAusland, Dr. R. B. Osgood, Dr. C. C. Simmons, Dr. F. J. Cotton and others have had such cases. This case is especially important because it was so carefully studied by men as well qualified to know a giant-cell tumor as anybody. I personally took the responsibility of not using post-operative x-ray treatment. I am not sure now whether such treatment should be advised as a routine, of course several of the other cases that had malignant changes recurred in spite of post-operative x-ray therapy. We have also had cases in which x-ray treatment alone was used but in which the same result occurred.

DR. CHANNING C. SIMMONS. I have very little to add to what Dr. Codman has already said. There are three possibilities. First, there is a type of central fibrous osteogenic sarcoma that is often confused with a giant-cell tumor because it contains a few foreign-body giant cells. These are central tumors with bone destruction which in the radiogram does not extend to the epiphyseal line, otherwise the films closely resemble those of giant-cell tumor. Microscopically, foreign-body giant cells are found in the periphery of the growth. There have been four cases of that character in the hospital. Secondly, I believe the pathologist cannot always tell whether a given giant-cell tumor is malignant or benign. Thirdly, I believe a great many of these cases are benign giant-cell tumors primarily, but as the process of repair goes on and there is an attempt to fill the cavity with normal bone, the mesoblastic tissue making this repair finally takes on malignant characteristics and becomes an osteogenic sarcoma. I believe that this patient had a benign giant-cell tumor in the first place, and as a result of the process of repair, she developed an osteogenic sarcoma. At the present time I think it is difficult to distinguish between the two latter groups.

#### CLINICAL DIAGNOSIS

Recurrent giant-cell tumor

#### DR. LUND'S DIAGNOSIS

Recurrent giant-cell tumor

#### ANATOMICAL DIAGNOSIS

Osteogenic sarcoma

#### PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY. I agree with Dr. Simmons. I find it difficult to believe that a mistake could have been made on the original tumor because both x-ray and histological findings were so perfectly typical of a benign giant-cell tumor. Benign giant-cell tumors can of course recur but usually in a much shorter period than four years. It would seem more reasonable to me to accept the simple explanation that Dr. Simmons gave, namely, that in the process of repair a true malignant osteogenic sarcoma developed.

#### CASE 25242

#### PRESENTATION OF CASE

*First Admission.* A forty-four-year-old white married woman was admitted complaining of pain in the left lower quadrant of the abdomen.

The pain first appeared about eight months before admission as a dull aching sensation in the left side of the lower abdomen an hour after eating. It occurred once a week and lasted from one to three hours. There were no other gastrointestinal disturbances. No medicinal or mechanical relief could be obtained. It seemed to be especially related to the eating of gas-producing foods. During the previous two months the pain had increased in intensity. Three weeks before entry the ache became unrelated to eating and was present when she assumed a sitting position. Bending forward caused increased pain, whereas standing gave partial relief. The pain had remained in the same position. She noticed tenderness in the left abdomen to her own palpation. The ache was noted every day until entry, lasted most of the day, and disappeared at night. It had never been sharp, had never radiated and was unrelated to respiration. During the previous two months there had been slight nausea in the morning, but she had never vomited, except on one occasion two weeks before entry after eating some fish which she ordinarily did not tolerate. During the previous two months she had had a diurnal frequency of five times and nocturia four times.

Her uterus had been removed two years previously for fibroids. She had severe headaches about once a month which lasted about six hours and seemed to be related to menstruation. She also had painful hemorrhoids. For the past six months she had had occasional hot flashes and

spells of weeping. Her past and family histories were otherwise noncontributory.

Physical examination showed a well-developed and nourished woman in no acute distress. Examination of the chest was negative. The blood pressure was 135 systolic, 74 diastolic. Deep palpation of the left abdomen beneath the costal margin gave the impression of a mass descending with inspiration. Pelvic examination revealed a moderately relaxed pelvic floor. Rectal examination showed a number of tender protruding hemorrhoids.

Examination of the urine was negative. Examination of the blood showed a red-cell count of 4,800,000 with 90 per cent hemoglobin, and a white-cell count of 8200 with 51 per cent polymorphonuclears. A blood Hinton test was negative.

X-ray films of the abdomen showed that the left kidney was obscured over its lower pole by a soft-tissue shadow which also partially obscured the psoas muscle. A retrograde pyelogram showed that the upper calices of the right kidney were deformed and pushed downward. The left kidney pelvis was large but not deformed. The ureters were normal.

The patient was kept in the hospital for nine days, but no obvious cause could be found for her complaints. The hemorrhoids were removed. She was discharged with a diagnosis of psychoneurosis, menopause, relaxed pelvic floor and fissure in ano.

*Second Admission* (seven years later). Two years before the second admission the patient entered the Out Patient Department, at which time two blood Hinton tests were positive, two Wassermann tests negative. She gave no history suggestive of primary or secondary syphilitic infection, and her husband had had a negative blood Hinton test in this hospital. She had had one miscarriage, her first pregnancy, but had three other children living and well. Her oldest daughter had had sore eyes at the age of nine years and subsequently had some injections at an outside hospital. The patient had become moderately obese during the past few years and was coming to the Out Patient Department for diet control. Twenty-two months before entry she was said to be losing weight too rapidly, had headaches, was nauseated and was unable to retain food. Two months later she complained of pain in the left axillary region, but examination of this region was negative. She continued having severe headaches about once each month, with hot flashes, nausea and vomiting. Four months later the blood showed a positive Hinton test and a weakly positive Wassermann test. She was being given courses of bismuth and salvarsan treatment. One

year before entry her youngest child, an eleven-year-old boy, entered the hospital with cirrhosis of the liver. His blood Hinton test was negative. X-ray films of the patient's chest ten months before admission were negative except for slight prominence of the left ventricle. Eight months before admission she had had a severe attack of upper abdominal pain occurring an hour after her evening meal, followed in two or three hours by severe vomiting and relieved by a hypodermic injection. Two months later she had had a similar attack. On each occasion the pain was gone the following day. Four days before admission, during the evening, there was a sudden onset of crampy, intermittent, severe upper abdominal pain, radiating to the back and to the right and left. Nausea and vomiting were associated with the pain so that she could retain nothing by mouth. The vomitus consisted of sour brownish material. During the day before admission she vomited almost continuously. She had had only one bowel movement during the four days. There had been no jaundice.

Physical examination showed a well-developed and nourished woman in obvious distress, complaining of abdominal pain. Examination of the chest was negative. The blood pressure was 120 systolic, 80 diastolic. The abdomen showed diffuse abdominal tenderness, without spasm but with slight distention and tympany. No fluid or masses could be made out. Pressure in the lower quadrants caused pain in the upper quadrants. Rectal examination showed tenderness on both sides. Pelvic examination was negative. The uterus was absent.

The temperature was 101°F, the pulse 110, and the respirations 20.

Examination of the urine was negative. The blood showed a white-cell count of 9000. The non-protein nitrogen of the serum was 17 mg per 100 cc, the chlorides 110.4 milliequivalents, and the van den Bergh 1.5 to 2 mg. A stool examination was guaiac negative.

A flat abdominal roentgenogram showed marked distention of the jejunal loops. There was little or no air in the lower small intestine and colon. A Graham test was positive.

On the third hospital day the patient had a chill followed by a temperature of 102°F. The chest was clear. She had no abdominal pain or tenderness. The skin was slightly icteric. Two days later she was doing well on a soft diet and had no pain, nausea or vomiting. Her chart was flat.

On the tenth hospital day an operation was performed.

## DIFFERENTIAL DIAGNOSIS

DR ROBERT R LINTON It appears to me as if this patient must have had something in her left upper abdomen on her first entry, although they did not include it on her discharge diagnosis. I also assume she had no further x-ray studies.

DR AUBREY O HAMPTON Not until 1934, two years later.

The right kidney deformity seems to be due to rotation from pressure of the liver. I do not believe there is a tumor of the kidney. The soft-tissue shadow described here is not very obvious.

DR LINTON The following points I believe are of significance. In a review of the first admission I am unable to make a definite diagnosis any more than the service was at that time. X-ray study showed that there was something in the left side of the abdomen and it seems a little odd that she did not have a gastrointestinal series and also a Graham test, if there was something pressing on the right kidney. It seems conceivable that it could have been a large gall bladder. It is not unusual in gall-bladder disease to have pain in the left side of the abdomen and even in the left lower quadrant. This is due to pancreatitis secondary to the gall-bladder disease.

"Her oldest daughter had had sore eyes at the age of nine years and subsequently had some injections at an outside hospital." That points toward a child with congenital syphilis. With these positive Wassermann tests we have to assume that the patient had a positive blood. Whether she had any other evidence of syphilis, I am not sure.

"One year before entry her youngest child, an eleven-year-old boy, entered this hospital with cirrhosis of the liver." That is a statement on which I should like a little more confirmation.

In summary I should say the diagnosis rests between two conditions. Are we dealing with gall-bladder disease with gallstones and pancreatitis or with partial intestinal obstruction? In reviewing her first admission the former diagnosis I should think is the one to favor. I shall rule out the kidneys as I see no further evidence that they were involved. The important thing is the question of gall-bladder disease and pancreatitis, and I do not think one can make a diagnosis of gall-bladder disease alone. Some other condition should be associated with it because of the fact that she had severe nausea and vomiting, and on account of the brownish character of the material she vomited. I have always remembered the teaching of Dr Daniel F Jones, that in simple gall-bladder disease patients very seldom, if ever, vomit to any degree, and that if they vomit large amounts and the vomitus is brownish in color, as in this case, one must look for some cause other than cholecystitis

and gallstones. Certainly pancreatitis, if associated with it, would produce such a picture.

She made quite a rapid response to conservative treatment, as I judge she was in fairly normal condition when they operated on her. A point I cannot overlook, however, in making a final decision in diagnosis is the x-ray report which says a flat abdominal x-ray film showed marked distention of the jejunal loops. There was little or no air in the lower small intestine or colon. In addition it is of significance that she had had only one bowel movement in four days. May we see the x-ray films?

DR HAMPTON The proximal loop of the jejunum is markedly dilated, and there is a very sudden stop in the upper abdomen with nothing to suggest dilated small bowel below the second loop of the jejunum. There are ten dense pills in this dilated loop, and if you knew when they were given, it might help a lot.

DR LINTON The fact that these pills were undissolved—I do not know what the pills are—rather points to the fact that they were being held up in the upper intestinal tract because of some obstructive lesion where you see the dilated loops of intestine. I think that this would also help explain the severe nausea and vomiting that she had prior to entry. It is a little surprising, however, that she got over this if she did have as complete obstruction as that would indicate. However, intestinal obstruction is sometimes intermittent due to a valve-like obstruction and the intestinal contents will pass along, especially if the obstructed loops are decompressed by nasal catheter drainage, until the upper loop becomes distended again.

I should say that there was no question that the cause of this patient's final admission to the hospital was intestinal obstruction involving the jejunum. The exact nature of the lesion I am afraid I cannot state. It was probably malignancy of some type. I do not believe it was a gallstone impacted in the jejunum, as gallstones, if they ulcerate through into the intestinal tract, are usually held up at the ileocecal valve. I have to make a diagnosis of cholecystitis, possibly cholelithiasis as well, but I think these are probably incidental. My final diagnosis is obstruction of the jejunum due to a malignant tumor, with a question of cholecystitis and cholelithiasis.

A PHYSICIAN What were the pills?

DR HAMPTON They remind me of sodium chloride pills. There are ten, and I wonder if they were given all at once.

DR FIORINDO A SIMEONE They were pills containing mercury that she was taking for anti-syphilitic treatment.

DR HAMPTON At what intervals?

DR. SIMEONE She took several a day She was not definite as to the number taken per day or at what intervals

DR. HAMPTON Do you think they had been there for days?

DR. SIMEONE I think so She did not remember when she took them

At operation she had a negative gall bladder The organ was thin walled, soft, not distended and compressed easily, and there was nothing palpable in the common duct Exploration of the abdomen revealed a tumor in the jejunum The tumor delivered into the wound very easily, it was in the antimesenteric wall of the jejunum and was shaped like the fundus of the uterus It was firm to touch and had small nodules over the surface measuring 0.5 to 1 cm across The nature of the lesion was not clear at the time It was resected and the continuity of the jejunum re-established by side-to-side anastomosis

DR. HAMPTON Did the bowel look as if it had been intussuscepted?

DR. SIMEONE No, but it looked as if there had been partial mechanical obstruction for some time The proximal end was somewhat dilated and hypertrophied

#### PREOPERATIVE DIAGNOSIS

Cholelithiasis and chronic cholecystitis

#### DR. LINTON'S DIAGNOSES

Malignant tumor of jejunum, with partial intestinal obstruction

Syphilis

Cholecystitis and cholelithiasis?

#### ANATOMICAL DIAGNOSIS

Malignant lymphoma, giant follicular type, of jejunum

#### PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY There was a quite marked, firm infiltration of the walls of the bowel for some distance, and the lesion was obviously neoplastic in gross We were considerably surprised, however, by the final microscopic findings since this turned out to be a lymphoma of the giant follicular type We have seen that type of lymphoma in many locations before, but we have never seen it as an isolated tumor of the bowel It is, of all forms of lymphoma, the most slowly growing and the most clinically benign, so I think it is within limits of probability that she had had this tumor throughout her history It is a little interesting that the medical student who saw her on the first entry made a diagnosis of lymphoma, though he did not place it in quite the right spot

In these lymphomas of the gastrointestinal tract surgical resection may be the best form of treatment We have had a number of cases with very long remissions—running from three to seven or more years—following surgical resection, and I think there is every reason to look forward to a long period of remission in this patient, although there is also no doubt that the tumor will eventually recur in some other spot

## THE ANNUAL MEETING

UNDER the auspices of the Worcester District Medical Society the City of Worcester opened wide its doors to welcome the Massachusetts Medical Society, June 6, 7 and 8, for the celebration of the one hundred and fifty-eighth annual meeting

The new beautiful and commodious Municipal Memorial Auditorium provided ample space and accommodations for the section programs, scientific exhibits, motion pictures and commercial displays as well as for the Council meeting and that of the Society

Registration was promptly underway at nine o'clock Tuesday, and practically all the exhibits were in order because of ample pre-convention time, in contrast with the confusion and noise of former years. This better state of affairs justified the

change of opening time from Monday to Tuesday

There was an unfortunate delay in getting the Bancroft Hotel Ballroom ready for the Shattuck Lecture, but the large assemblage waited patiently until arrangements were completed, and Dr. Wilder Penfield must have been gratified with the close attention of the audience, which was treated to a scholarly and illuminating discussion of epilepsy and cerebral lesions of birth and infancy, with records of the results of treatment. This delay was no fault of the Committee of Arrangements

The educational exhibits were of exceptional quality and were studied carefully by a large proportion of the fellows because of the variety and practical importance of the subjects presented. These, together with the motion pictures, made contributions to postgraduate education which were enthusiastically approved

There were 1134 fellows and 257 ladies in attendance during the three days, making a total registration of 1391 thereby exceeding that of any previous annual meeting of the Society outside of Boston

For the first time, the section meetings were carried through on a continuing program. As in previous years, the same was true of the combined meeting on Wednesday morning. This custom was generally approved. The only overlapping exercises were the round-table discussions on Wednesday afternoon

Guest speakers from many important clinics brought the consensus of medical teaching to amplify the addresses of our members. The subjects which drew the largest audiences were medicine, surgery and obstetrics. The number in attendance at each exercise has been kept by the Committee of Arrangements for future reference

There was a large attendance at the Council Meeting and the routine business of acting on the designated subjects was carried through as promptly as possible. Valuable information with suggestions for endorsement of resolutions or recommendations which were not of a controversial nature were submitted by several of the committees. Those presented by the Committee on State and National Legislation were so extensive, dealing as

they did with matters before the state legislature and Congress, that there was room for differences of opinion as to procedure. So far as state matters are concerned, the chairman reported success in overcoming unapproved bills but inability to secure legislative approval of all those measures which had been endorsed by the Council. He then made a detailed report of the situation with respect to the Wagner Bill and the conferences which had been held with the Massachusetts senators and with representatives of the American Medical Association. There were various suggestions as to the proper procedures to be followed in efforts to remove from the Wagner Bill those features which are inimical to the interests of the profession, and as a reflection of these differences of opinion, the nominations of the President for members of the Committee on State and National Legislation for the ensuing year were not unanimously acceptable and others from the floor were presented, this was followed by a vote by ballot for members of the committee. The result was not announced until the afternoon, the members of the new committee are Drs. Charles C. Lund (chairman), Earle M. Chapman, Brainard F. Conley, David L. Lionberger and Charles A. Robinson. All other committees were duly elected without contest.

On nominations by the committee acting under the provisions of the by-laws the following designated officers were elected to serve for the ensuing year: president, Dr. Walter G. Phippen, of Salem, vice-president, Dr. A. Warren Stearns, of Billerica, secretary, Dr. Alexander S. Begg, of Boston, treasurer, Dr. Charles S. Butler, of Boston, and orator, Dr. W. Jason Mixer, of Boston.

The proposed changes in the by-laws, copies of which had been sent to the councilors, were presented for action. With the exception of Amendment 4 and its corollary, Amendment 6, which were not approved, and a change in the wording of Amendment 3, the list was approved and forwarded to the annual meeting of the Society for final disposition.

Three hundred and thirty-two fellows and guests participated in the annual dinner at the Hotel Bancroft, Wednesday evening. The postprandial

exercises included the distribution of the prizes awarded to the golfers by the president, with appropriate witty comments, and an address by Mayor Bennett, of Worcester. The latter assured the Society of his appreciation of the honor conferred in the selection of the "Heart of the Commonwealth" for an annual meeting and, after urging doctors to devote more time to civic responsibilities thereby bringing to bear the influence of educated citizens on municipal problems, he cordially invited the Society to make Worcester its meeting place as often as possible. The orator of the occasion was the Honorable Henry Parkman, Jr., corporation counsel for the City of Boston and general chairman of the Tufts College Medical School Development Program. In regard to the latter, which is committed to the education of general practitioners for rural communities and also to such postgraduate instruction as may be needed by doctors of advanced age living away from medical centers, he explained the close association of Tufts College Medical School with the New England Medical Center, of which the Boston Dispensary is an integral part. All the details of this department were set forth and prominence was given to the provisions for substitutes who are assigned to fill the positions held by practitioners who wish to spend a month at the medical center for studying modern diagnostic methods and the latest advances in treatment. Credit was given to Tufts College Medical School for taking a forward step in meeting an obvious social obligation.

At the conclusion of the scientific program the annual meeting was called to order by the president, Dr. Channing Frothingham. The incoming president, Dr. Phippen, was introduced and, in response, assured the Society of his appreciation of the honor conferred on him and asked for the co-operation of every member in carrying forward the functions of the Society. The secretary, Dr. Begg, reported that the membership of the Society is now 5432, a gain of 127 over that of last year. He read the several amendments to the by-laws which had been approved by the Council, the approval of the Society was voted. The Presi-

dent then read his report on the state of the Society, in which he reported that the financial condition is sound and well managed by the treasurer, Dr Butler, and that the committees of the Society had diligently and faithfully carried on the tasks assigned to them. Explanations were given of changes which had taken place in the personnel of these committees. Comments on the important problems before the profession were submitted.

The orator, Dr Elliott P Joslin, then read the annual discourse, in which he dealt with the many phases of "social medicine," words which he preferred to use rather than those of "socialized medicine." This included many of the social, economic and professional functions connected with plans for dealing with the health of the people. The latter part of his address was devoted to a consideration of medical education and the quality of the physicians who are to take the places brought about by the yearly loss of active practitioners. This address will interest all members of the Society who are conversant with problems connected with medical education and professional responsibilities relating to the health of the people and should stimulate discussions of the implications of the propositions outlined by the author.

It is hoped that these brief comments on the annual meeting will induce the fellows of the Society to read the official reports of the proceedings which will be published in the *Journal* at an early date.

---

## A POSTGRADUATE TOUR IN THE SEVENTEENTH CENTURY

WHEN Edward Browne, the son of Sir Thomas Browne, returned from Cambridge University to his father's house in Norwich at the age of nineteen, with his M.B. degree, he, like many other medical students, was disturbed about his future. Should he go to London for hospital work, wait for practice at home, or spend his time in his father's ample and hospitable library, reading

botany, literature, medicine and theology? He chose the latter course and supplemented his reading with daily dissections of animals. He saw at least one patient and received his first fee of ten shillings. Later he attended a few lectures at St. Bartholomew's Hospital in London and vacationed in Italy and France. He was elected a fellow of the Royal Society when he came of age, largely, one presumes, on his father's reputation.

At the age of twenty-three he took up traveling in earnest and for the next five or six years spent most of his time in Europe. His observations were published in two short books, *A Brief Account of Some Travels* (London, 1673) and *An Account of Several Travels* (London, 1677). Both were reissued in a sumptuous second edition, this time one volume in folio (London, 1685). This edition is, in all respects, the best book of the three.

Browne was an accurate and painstaking observer, but his style of writing was dull, and the first book is hardly more than a catalogue of towns, buildings and matters of historical interest. The second book was a little more lively, and there are interesting descriptions, such as that of the Imperial Library at Vienna, its contents and his friendship with the librarian, Lambecius. Browne made a few gifts to the library and gained, through the librarian, a formal pass from Emperor Leopold, exempting him from customs on the way back to England. In Thessaly he remained for some time at Larissa, visualizing the Hippocratic country, but one can hardly agree with Norman Moore\* that Browne "followed in imagination the practice of Hippocrates." In none of his writings, moreover, is the depth found that was so characteristic of his father's works.

On his return from his travels, Browne practiced in London and became surprisingly successful. In addition he wrote the earliest known copy of the *Pharmacopoeia of St. Bartholomew's Hospital* (London, 1670).

## LATE POSTPARTUM HEMORRHAGE

Mrs. N. L., thirty-five-years old, was readmitted to the hospital on December 15, 1938, twenty-six days after the normal delivery of her first baby, with a chief complaint of vaginal bleeding.

The family history was essentially negative. The patient had had a cholecystectomy and appendectomy seven years previously. In December, 1937, she had had a complete miscarriage at approximately the sixth week of pregnancy. Catamenia began at thirteen, were regular with a twenty-eight-day cycle and lasted three days with out discomfort. Her last menstrual period was January 30, making her due for delivery November 6.

She was seen regularly in the prenatal clinic of the hospital from the fifth month of her pregnancy, and at no time were there abnormal signs or symptoms.

On the afternoon of November 19, the patient was admitted to the hospital in active labor. During the first stage of labor 6 gr. of Nembutal were given. At 10.30 p. m. a normal living infant in ROA position and weighing 7 pounds, 12 ounces, was delivered spontaneously. An ampule of Pitocin was given subcutaneously. While awaiting the expulsion of the placenta and membranes, which, when delivered, appeared to be intact, a first-degree laceration of the perineum was repaired. Blood loss was estimated at 350 cc. Following expulsion of the placenta, 1/320 gr. of Ergotrate was administered subcutaneously, after which the uterus contracted firmly. The fundus was held for an hour. Tablets of Ergotrate (1/320 gr.) were given every four hours for six doses. The puerperium was uneventful. The discharge note, made on December 1, read "General condition good, uterus well involuted, anterior, freely movable, non-tender, perineum healed, relaxed, cracked nipples, lochia alba, slight, vaults non-tender and free of masses."

On December 15, two weeks after discharge, the patient was readmitted to the hospital as stated above. She described an initial profuse hemorrhage occurring December 8, followed by intermittent spotting until the evening before admis-

sion when another profuse hemorrhage occurred. Her family physician referred her back to the hospital. The temperature was 98.6°F., the pulse 76, the respirations 20, and the blood pressure 106 systolic, 70 diastolic. On physical examination there were a well-healed scar in the right upper quadrant, tenderness without spasm in both lower quadrants, a midline smooth rounded mass palpable just above the symphysis pubis, and vaginal bleeding of a slight degree. The red-blood-cell count was 3,870,000 with 75 per cent hemoglobin, and the white-blood-cell count 13,300. Urinalysis revealed a specific gravity of 1.028, an acid reaction, a trace of albumin, no sugar, gross blood, and many red cells and an occasional white cell in the sediment.

The patient was placed in Trendelenburg position and the vulva prepared. An ice bag was placed on the lower abdomen. A quarter grain of morphine and an ampule of Ergoklonin were administered subcutaneously. Morphine (1/6 gr.) was given every four hours for four doses, Ergotrate (1/320 gr.) was given every four hours for five doses. A four-hour chart with blood pressure readings was kept. Bleeding ceased altogether on December 19 and did not recur. The temperature remained normal, and the pulse never rose over 90 during the hospital stay. On December 24, the patient left the hospital. The uterus was well involuted, and no recurrence of bleeding occurred.

*Comment.* It is perfectly possible that the severe bleeding that occurred on December 8 and December 14 may have been caused by the retention and separation of a small piece of placenta and that the bleeding on December 15 at the time of admission was accompanied by the complete expulsion of all pieces of retained tissue. It is uncommon for bleeding such as this to occur unless associated with some form of retained products, however, it is very common for the first period after any delivery to be extremely excessive and occasionally so excessive that curettage becomes a necessity. Subinvolution is more frequently associated with continued dribbling than with excessive hemorrhage. Conservatism in the handling of this case after re-entry was stimulated by the fact that the bleeding had practically ceased, and it is quite probable that if the bleeding had recurred the uterus would have been invaded.

## MISCELLANY

## TUBERCULOSIS IN INDUSTRY

To what extent tuberculosis may be regarded as an industrial hazard is engaging the attention of industrial leaders, legislators and physicians. Not only occupation but also several other factors are responsible for tuberculosis among industrial workers. Ornstein and Ulmar

A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

dent then read his report on the state of the Society, in which he reported that the financial condition is sound and well managed by the treasurer, Dr Butler, and that the committees of the Society had diligently and faithfully carried on the tasks assigned to them. Explanations were given of changes which had taken place in the personnel of these committees. Comments on the important problems before the profession were submitted.

The orator, Dr Elliott P Joslin, then read the annual discourse, in which he dealt with the many phases of "social medicine," words which he preferred to use rather than those of "socialized medicine." This included many of the social, economic and professional functions connected with plans for dealing with the health of the people. The latter part of his address was devoted to a consideration of medical education and the quality of the physicians who are to take the places brought about by the yearly loss of active practitioners. This address will interest all members of the Society who are conversant with problems connected with medical education and professional responsibilities relating to the health of the people and should stimulate discussions of the implications of the propositions outlined by the author.

It is hoped that these brief comments on the annual meeting will induce the fellows of the Society to read the official reports of the proceedings which will be published in the *Journal* at an early date.

---

## A POSTGRADUATE TOUR IN THE SEVENTEENTH CENTURY

WHEN Edward Browne, the son of Sir Thomas Browne, returned from Cambridge University to his father's house in Norwich at the age of nineteen, with his M.B. degree, he, like many other medical students, was disturbed about his future. Should he go to London for hospital work, wait for practice at home, or spend his time in his father's ample and hospitable library, reading

botany, literature, medicine and theology? He chose the latter course and supplemented his reading with daily dissections of animals. He saw at least one patient and received his first fee of ten shillings. Later he attended a few lectures at St. Bartholomew's Hospital in London and vacationed in Italy and France. He was elected a fellow of the Royal Society when he came of age, largely, one presumes, on his father's reputation.

At the age of twenty-three he took up traveling in earnest and for the next five or six years spent most of his time in Europe. His observations were published in two short books, *A Brief Account of Some Travels* (London, 1673) and *An Account of Several Travels* (London, 1677). Both were reissued in a sumptuous second edition, this time one volume in folio (London, 1685). This edition is, in all respects, the best book of the three.

Browne was an accurate and painstaking observer, but his style of writing was dull, and the first book is hardly more than a catalogue of towns, buildings and matters of historical interest. The second book was a little more lively, and there are interesting descriptions, such as that of the Imperial Library at Vienna, its contents and his friendship with the librarian, Lambecius. Browne made a few gifts to the library and gained, through the librarian, a formal pass from Emperor Leopold, exempting him from customs on the way back to England. In Thessaly he remained for some time at Larissa, visualizing the Hippocratic country, but one can hardly agree with Norman Moore\* that Browne "followed in imagination the practice of Hippocrates." In none of his writings, moreover, is the depth found that was so characteristic of his father's works.

On his return from his travels, Browne practiced in London and became surprisingly successful. In addition he wrote the earliest known copy of the *Pharmacopoeia of St. Bartholomew's Hospital* (London, 1670).

directed attention to the relation of trauma to tuberculosis. Tuberculosis has a specific etiology and, therefore, trauma cannot produce the disease. Trauma can, however, reactivate a previously existing active tuberculosis. Most of the confusion comes from the varied opinion concerning the time interval which may elapse from the date of the injury to recognition of the tuberculous disease.

Gases and vapors may also activate a pre-existent pulmonary tuberculosis by producing an inflammatory process in the vicinity of the pre-existing disease by irritant chemicals.

Trauma plays an important role in tuberculosis of organs other than the lungs. In this group the time element creates difficulties because of the inability to demonstrate the immediate spread of tuberculosis. Reprinted from *Tuberculosis Abstracts* June, 1939

#### NOTE

Dr Douglas A Thom, professor of psychiatry at Tufts College Medical School, was elected president of the American Psychopathological Association at its recent meeting in Atlantic City. He succeeds Dr Abraham Myerson, who was elected to the council.

### CORRESPONDENCE

#### AN AMERICAN HEALTH INSURANCE PLAN

*To the Editor* This plan compels the man or woman on salary to save in the savings department of a bank. A certain amount, estimated at 4 per cent of the salary, is earmarked and only used for sickness and accidents to pay the hospitals, physicians, nurses, dentists and druggists. This takes in every man and woman on salary and should be handled directly by the employer who places the money on deposit in the bank in the name of the employee.

It does not put the medical or dental profession into politics or allow control of the professions by the Government. It does not increase the number of government employees, nor does it put an increased burden on the Government or professions. It will decrease taxation as there will be fewer charity patients in the federal, state, county and city hospitals, since their compulsory savings make them financially independent, also it will help other hospitals for the same reason.

This fund cannot be used for automobiles, gay parties or gambling. The compulsory part of this deposit should accumulate as long as the employee is working. The employee should receive interest as in a savings account to be added to the principal or withdrawn as he sees fit. Any person not on salary should be allowed to deposit in the same way. On the death of the employee this deposit would act as a life insurance after all bills are paid.

This will tend to prevent the isms in government—Communism, Fascism, and so forth—and show the people the way to save.

ARTHUR N. MAKACHNIE, M.D.

### REPORT OF MEETING

#### HARVARD MEDICAL SOCIETY

At the regular meeting of the Harvard Medical Society on Tuesday, February 28, in the Peter Bent Brigham Hospital amphitheater, Dr W. T. Salter presided. The program was opened by the presentation of two cases.

The first case, from the surgical wards and presented by Dr Fred Lescmann, was that of a thirteen year-old boy who was brought in following a coasting accident in which he ran into a tree and injured his left side. There was no loss of consciousness, only pain. Physical examination revealed an acutely ill boy breathing rapidly and distressfully. There was a small contusion over the ribs in the left posterior axillary line. Hyperresonance with decreased breath sounds and absent tactile fremitus was found over the left chest, and the heart and mediastinum were displaced to the right. X-ray examination confirmed the diagnosis of hydropneumothorax. A trocar allowed evacuation of blood and air, with considerable relief to the patient. For the next thirty six hours there was drainage of a moderate amount of blood. The temperature began to rise and remained in the vicinity of 104°F rectally for eleven days. *Staphylococcus aureus* was cultured from the drainage tube. One hundred to two hundred cubic centimeters of purulent material was drained, following which the temperature began to subside, and since then, drainage under water has been followed by an increase in the lung shadow and a decrease in the fluid shadow by x-ray.

Dr Robert Gross mentioned the two ways in which traumatic rupture of the lung can occur: either as a result of fractured rib tears, or spontaneously when the glottis, diaphragm and rib cage are held rigidly fixed. The flap of torn lung tissue acts as a valve, trapping inspired air which collects in a few hours and forces the mediastinal contents over. It is a real emergency. The chest can be aspirated, or it may be necessary to open it surgically and allow the injured lung to remain collapsed until it heals. Dr O'Hare brought out the point that cases have been cited as having been caused by yawning or stretching.

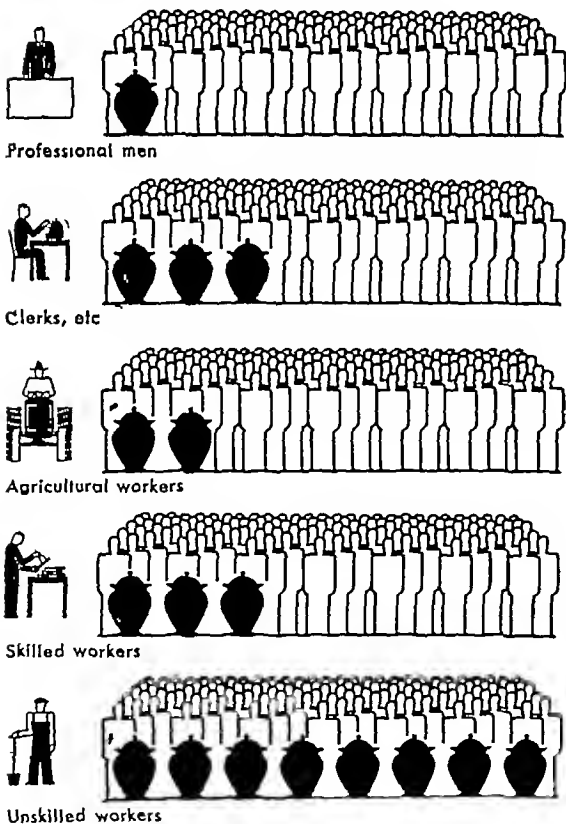

(Tuberculosis in industry *Quart Rev Sea View Hosp* 4 164-181, 1939) analyze these factors Excerpts from their paper follow

The death rate among the unskilled workers is more than twice that of the skilled workers Is this due to the industry or to lesser earning capacity? It is more probably due to the latter

Is tuberculosis an occupational disease? An occupational disease is one that arises out of the occupation per se. There must be a definite relation between the etiology of the disease and the occupation. The frequency of the occurrence of the disease in the occupation must be greater than the incidence of the disease in a similar group not so employed A high frequency of tuberculosis in a particular industrial group may be due to the fact that the labor is recruited from a section of the city where tuberculosis is more prevalent than it is in other sections Unskilled labor comes chiefly from those parts of the city where the tuberculosis death rate is high

In a few definite groups only may tuberculosis be considered as an occupational disease. These groups include *Workers caring for the tuberculous sick—nurses orderlies attendants, and so forth* The frequency of the

### Occupation Influences Tuberculosis

N T A Isotype Chart

occurrence of tuberculosis infection and disease among medical students and nurses has been noted by numerous workers There can be no question but that the opportunity for exogenous infection of the lungs by the tubercle bacillus presents itself in the care of the tuberculous sick. At Sea View Hospital, New York City, x ray evidence of pulmonary tuberculosis was found in 10 of the

1000 nurses during the period from 1930 to 1935, and 21 others developed lesions in the lungs while working in the hospital Of the 10 cases which showed evidence of disease on admission, 7 continued to work with either clearing or no change in the lesion, 1 broke down with a cavity and 2 did not start work. It is most important to note that while the incidence rate was low in the Sea View group (1 per cent) the occurrence rate was high, which indicates a definite hazard from an insurance standpoint. By contrast, the tuberculosis occurrence rate among employees of a large department store was found to be a small fraction as compared with that of the nurses group

Similar studies made among medical students have tended to show an increased incidence of tuberculous disease among them, presumably due to their occupation, which throws them in contact with open tuberculosis cases

In a great many general hospitals, the frequency of implantation of tubercle bacilli in the previously non infected probationers has been almost as great as that in the tuberculosis wards Many cases of open tuberculosis are admitted to the general hospital for surgical and other forms of treatment. The tuberculous disease is not suspected and the nurse takes no precautions against exogenous cross-infection while she attends the patient. The contact may be a continuous one without the tuberculous disease ever being discovered. The nurse later breaks down with the disease. The question of whether the tuberculosis acquired in a general hospital is an occupational disease will depend a great deal on the frequency of the admission of the tuberculous to the hospital

*Store clerks, saleswomen, waiters, conductors and others who have contact with a large number of people in whom there may be a high incidence of tuberculous disease* The presumption that the tuberculosis acquired in these occupations may be classed as occupational is based on the many opportunities for contact with open cases of pulmonary tuberculosis There must be a wide variation in the opportunities of contact infection in districts with small or high incidence of clinical tuberculosis Think of the possibility of such contact in the 5 and 10 cent stores in neighborhoods of low economic standards There are no definite figures as yet in such industries but the general impression is that the occurrence is frequent. The workers are not recruited from the slum sections, in some of the large cities they come from a good middle class where the incidence is not high

*Workers exposed to silica dusts* Silicosis is definitely an occupational disease. Many investigators have associated silicosis with the occurrence of pulmonary tuberculosis, but the authors dispute the commonly accepted belief that the deposit of silica in the lungs renders the lungs susceptible to infection by tubercle bacilli That most of the silicotics die of pulmonary tuberculosis is a debatable question

The present concept of the high mortality of tuberculosis is founded, not on extensive autopsy series, but rather on the computations of vital statistics This is a source of grave error, for not only can mistakes in diagnosis be made by the clinician so that the basis of the statistics is wrong, but also misleading conclusions can be drawn from the existing figures

The authors warn of the dangers of error in differentiating between silicosis and pulmonary tuberculosis, challenge the high frequency and death rate of tuberculosis as a complication of silicosis and assert that clinical tuberculosis should not be diagnosed in silicosis unless tubercle bacilli are demonstrable in repeated sputum examinations

*Workers exposed to trauma* Compensation laws have

patient who was on digitalis therapy for previous myocardial failure. In the seventh week of cyanate treatment, the blood pressure having been reduced from 240 systolic, 140 diastolic, to 150 systolic, 100 diastolic, nocturnal dyspnea and rales appeared. Treatment was stopped, and the signs disappeared. One year later the patient died of a cerebral accident, with a blood pressure of 250 systolic, 130 diastolic.

Three patients developed hallucinatory psychoses the first at a blood-cyanate level of 10 mg per 100 cc, having had a control systolic pressure of 275 mm, the second at 14 mg, after having had no drop after one month of therapy from the control systolic pressure of 300 mm (a true cyanate intoxication), the third overdosed herself to a blood-cyanate level of 24.9 mg, her pressure having dropped from 250 systolic, 140 diastolic, to 200 systolic, 100 diastolic. The last patient returned to normal mentality in three weeks, when the cyanate level had been reduced to 15 mg.

Five of these 6 patients with serious effects were over fifty-five years of age. All had a very high degree of hypertension, and 4 of them had had previous serious episodes such as strokes, angina pectoris, heart failure, and so forth. It is to be concluded, therefore, that the choice of patients for cyanate therapy must depend on their having uncomplicated essential hypertension, preferably under the age of sixty. A blood-cyanate level of 14 mg per 100 cc. should be the absolute maximum, whereas a lower concentration should be maintained if possible. Finally, if there is a poor effect following a level of 10 to 14 mg for from two to four weeks, administration of the drug should be stopped. Carefully controlled, cyanate therapy is of definite value, in Dr Robinson's opinion.

In opening the discussion of Dr Robinson's paper, Dr O'Hare's comment was that, although cyanate therapy in carefully selected cases of hypertension offered more than did any other therapeutic method, it is not the ideal remedy because of the drug's toxicity. Until a better method is available it will serve a very useful purpose.

Dr Samuel Levine asked about the effect of cyanate on Goldblatt dogs, to which Dr Robinson quoted Barker's results showing no effect. It was said that, at the Massachusetts General Hospital, good results with cyanate therapy had been obtained in 2 cases out of a small series of 29.

Dr Robinson, in answering questions put to him, replied that the symptom of weakness was often temporary, disappearing when the patient became adjusted to the lower blood pressure level. He added that cyanate resistance, so-called, is a doubtful entity, since patients are responsive the second time the drug is tried after resistance to the first attempt.

## NOTICES

### REMOVAL

FRANCIS J McNAMARA, M.D., announces the removal of his office to 106 West Foster Street, Melrose.

### BOSTON DISPENSARY

A luncheon meeting of the clinical staff of the Boston Dispensary will be held on Wednesday, June 21, in the auditorium of the Joseph H. Pratt Diagnostic Hospital at 12 o'clock noon.

The program, under the auspices of the laboratory department, will begin at 12:30 p.m.

Laboratory Diagnosis of Rabies. Dr William A Hinton.

Some Vascular Measurements in Hypertension. Dr Harold E MacMahon.

A Fatality From Acute Hemolytic Anemia Which Developed During the Administration of Sulfanilamide. Dr Harold Wood.

All interested in the subject are cordially invited to attend.

ROBERT W BUCK, M.D., *President*  
JAMES M. BATY, M.D., *Secretary*

### SOUTH END MEDICAL CLUB

The next meeting of the South End Medical Club will be held at the headquarters of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston, on Tuesday, June 27, at 12 o'clock noon. Dr Auerbach, pathologist, Sea View Hospital, New York City, will speak on 'Pathogenesis and Management of Tuberculous Pleural Empyema' and will show lantern slides.

Physicians are cordially invited to attend.

JOHN B HALL, M.D., *Secretary*

### CARNEY HOSPITAL

The monthly clinical meeting and luncheon of the Carney Hospital will be held in Andrew Carney Assembly Room on Monday, June 19, at 11:30 a.m.

ROY J HEFFERNAN, M.D., *Secretary*

### AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY

The American Board of Obstetrics and Gynecology announces that at the recent examinations held by the Board at St. Louis, Missouri, on May 13, 14, 15 and 16 two hundred and fifty-nine candidates were examined. Two hundred and twenty-eight candidates were successful in the examinations and were certified by the Board, twenty-nine candidates failed, and two examinations were not completed by the candidates.

At the annual meeting of the Board, held in St. Louis on May 12, it was found necessary, on account of increased administration expenses, to increase the application and examination fees. Effective immediately, these are to be as follows: application fee \$15.00, payable on submission of application for review by Board, examination fee \$75.00, payable on notification to candidate of acceptance of the application and assignment for examination. Neither fee is returnable. This increase does not apply to candidates whose applications were filed prior to May 12, 1939.

The next written examination and review of case histories (Part I) for Group B candidates will be held in various cities of the United States and Canada on Saturday, December 2, 1939, at 2:00 p.m. The Board announces that it will hold only one Group B Part I examination in this and subsequent years. Candidates who

The medical case was presented by Dr Albert C England. A thirty-five-year-old man was admitted for a check up on his high blood pressure. In November, 1938, he had had an attack of intestinal grippe, and the local physician had told the patient his blood pressure was very high, advised him to go on a low protein diet and gave him some medication, the patient kept on with his work. One week previously, which was two days before entry, the patient had a similar attack of abdominal cramping pains and decided to go to the hospital. Physical examination of the ocular fundi showed marked papilledema, the arteries were thickened and tortuous, and arteriovenous nicking was demonstrable. There were white exudates in a radiating star pattern at the maculas. His heart was moderately enlarged, extending 14 cm. out in the sixth left interspace, and there was a Grade 2 systolic murmur. The second aortic sound was loud and ringing. His blood pressure was 235 systolic, 160 diastolic, and slightly higher in the leg. The lungs were clear, the liver normal, and there was no edema. Urinalysis revealed a specific gravity of 1.010, none to a very slight trace of albumin, casts and cells. The red-blood-cell count was 5,000,000 with 70 per cent hemoglobin, the stools were guaiac negative, the phenolsulfonephthalein test gave a value of 45 per cent in two hours and ten minutes, the serum nonprotein nitrogen was 31 mg., the total protein 6.5 gm., the albumin 3.8 gm., and the globulin 2.7 gm. per 100 cc. The patient has been quite comfortable. The diagnosis was malignant hypertension.

The main part of the program of the evening was given over to Drs Roger W Robinson and James P O'Hare. Dr Robinson presented the paper "Further Experiences with Cyanate Therapy in Hypertension."

Briefly reviewing the work done on this subject, Dr Robinson stated that in 1901 sodium cyanate was first tried because of its similarity in action to that of the bromides, which are used in sedation and show a side effect in reducing hypertension. In 1925 Nichols revived interest in the drug but found nothing to recommend it because of its serious toxic effects. The dosage used at the time was 0.6 gm. daily. In 1931, Dr O'Hare and others tried the drug and found it lowered blood pressure in only 2 of 25 cases and produced toxic symptoms in almost all of them. Finally, Barker in 1936 discovered that, by maintaining an effective blood concentration of 6 to 10 mg per 100 cc., lowering of pressure could be obtained and toxicity avoided. He discovered that there was a very large factor of individualization of dosage, and explained on this basis the previous failures cited above. Forty-five patients were treated by him with enthusiastic results. Dr O'Hare decided to give it another try. The method of experimentation consisted in establishing a three-month control period, followed by three months of medication, and succeeded by another control period in which the drug was removed from the vehicle without the patient's knowledge—to avoid psychotherapeutic effects. Of 15 patients, 10 showed a significant drop in blood pressure and cessation of headaches. These results were reported in the *New England Journal of Medicine* (219:736-740, 1938). Since then the work has been extended until at this reading the results on 75 patients are available.

Because of the known toxic action of cyanate, complicated cases of vascular hypertension were, by and large, avoided. However, 4 of the 75 had had strokes, 1 had had angina pectoris, 1 a mild decompensation and 1 nephritis with impaired renal function. These 7 were treated very conservatively. All the patients were placed on the usual hypertensive regimen and had a control period of three months, during which sedation alone was given. Thirty-

three patients were followed for one year. Preliminary dosage consisted of 0.2 gm three or four times a day for three or four days. Following this the cyanate in the blood was determined, and the optimum dose was usually found to be 0.2 gm. twice a day, estimated on the basis of the cyanate level and the blood pressure. Often, a satisfactory level, namely, one in which there was a good drop in blood pressure without toxic signs, could be maintained by doses as low as 0.2 gm twice a week. The known cyclical nature of blood pressure readings in hypertension was taken into account, and psychological factors were evaluated, so far as possible.

Eighty-eight per cent of the cases showed a drop in systolic pressure of at least 30 mm. of mercury, and 11 per cent 60 mm or more, 62 per cent had a diastolic drop of 20 mm, 16 per cent of 30 mm. Three cases had a drop of 100 mm. systolic, 35 mm diastolic, for five months. One case, that of a young woman, has been on a cyanate regime for a year with good results. There were 9 cases with no drop in blood pressure. 3 of these in young patients with high diastolic pressures, 2 in elderly patients with arteriosclerosis, 3 in which the treatment was discontinued because of reactions, and 1 which was not adequately treated. The lowest blood pressure readings corresponded with the highest blood-cyanate levels and conversely. The usual marked fluctuations of blood pressure in such cases were much reduced by cyanate. Eighteen out of 20 had complete relief from hypertensive headaches.

There are many reasons that might explain these results such as an effect on the heart muscle, vasodilatation, lowering of blood viscosity by reducing its fibrinogen or total protein content, or a decrease in the oxygen consumption of all body tissues.

Twenty-nine patients exhibited toxic symptoms of one type or another. Of these, 23 cases were classified as mild. Weakness and lack of energy were the most frequent symptoms, occurring in 12 cases. In only 2 were they severe enough to require abatement or cessation of therapy. An experiment in the oxygen consumption of liver tissue offered a probable explanation for this weakness. It was noted that as the concentration of cyanate in the blood increased, the oxygen consumption decreased.

Skin manifestations of toxicity manifested themselves either as macular erythematous patches or as a rash simulating seborrheic dermatitis. Some patients gave reactions due to special sensitivity to the drug. Some had the rash only when drug resistant and, therefore, a blood-cyanate concentration of 12 to 17 mg per 100 cc. was maintained. Such rashes were transient, disappearing when the dose was decreased. One patient, however, had a generalized exfoliative dermatitis, a serious complication, but recovered. Three cases had areas of purpura during treatment, and an increased tendency to bleed.

Two male patients reported a decrease in libido.

There has been a question of the production of thrombosis following the lowered blood pressure, but to date no myocardial damage as a result of cyanate therapy has been proved. One elderly patient, however, had an attack of angina pectoris when his blood pressure dropped from 290 to 210 mm. Another patient, aged sixty-two years, with angina and an extremely high blood pressure, was successfully treated with cyanate. However, eleven months later he had a sudden hemiplegia. Whether the cyanate produced this by lowering the pressure too much was not certain, but seemed unlikely in view of the fact that its general level was 198 systolic, 108 diastolic.

One case of congestive heart failure occurred in a pa-

gima. The book aims at furnishing the lay reader with unbiased findings and compilations from the best medical and scientific sources of the past two decades.

This book is just not another book on alcohol, but rather it offers an appeal to reason, judgment and intelligence from the medical, psychological and general hygienic aspects. Alcohol is not presented as a moral issue, though the effects of overindulgence on morals and behavior are not slighted. The book reports simple, concise facts regarding the effects of the use and abuse of a most important drug. It is an unprejudiced textbook relative to the physiological and psychological effects of alcohol. A few popular theories are exploded. The study presupposes an elementary knowledge of anatomy and physiology. Individual differences in susceptibility are stressed, as well as individual tolerance.

Statistical data are not given in detail but are summarized and analyzed in some cases to representative figures from national and local governmental authorities. The chapter on statistics is divided as follows: the supply and consumption of alcohol, drunkenness, accidents in their relation to alcohol, automobile accidents and non automobile accidents, crime in relation to alcohol, alcoholic mental diseases, mortality from alcohol.

This book emphasizes the facts that education is necessary in solving the problem of alcohol and that sobriety cannot be legislated nor can fear be used to influence public attitudes as regards the use of alcohol. It is indicated that the process of education must be informative and without bias and prejudice.

The last chapter is devoted to opinions of eminent specialists covering the crucial topics concerning alcohol and the human body.

The glossary is well arranged and explains many of the technical terms used in the text.

*Adventures in Respiration. Modes of asphyxiation and methods of resuscitation.* Yandell Henderson. 316 pp. Baltimore: Williams & Wilkins Co., 1938. \$3.00.

This volume is essentially a scientific autobiography. In it the author reviews his lifelong study of the physiology and pathology of breathing, and the practical application of the principles derived therefrom. The story covers a period of thirty years or more. It is written in that imitatively emphatic, yet good natured, style which is characteristic of Professor Henderson. Often criticized, he yet remains always cordial to his critics, which is more than can be said of some scientists.

His major thesis, and one first advanced by him at the beginning of his professional career, is that acapnia, or deficiency of carbon dioxide, which leads in turn to anoxia, or a deficiency of oxygen, is a factor of importance in many ills and adversities encountered by the human organism, as, for example, the depression of vitality after anesthesia, surgical operation, traumatic shock or severe illness of various sorts. He intimates that, where as he was never able to sell this theory to the intellectuals, nevertheless the present-day general use of carbon dioxide in the operating room and hospital ward gives it considerable vindication.

A prerequisite for living is an adequate supply of oxygen. An exclusion of oxygen extinguishes a fire, so too in a man or animal a deficiency of oxygen in the blood and tissues induces death in asphyxia. In dealing with the problems of asphyxia, however, the author emphasizes that acapnia must be considered as well as anoxia for the reason that a diminished supply of oxygen in the lungs and blood always induces a diminution of the content of carbon dioxide also by overbreathing and in other ways, and that not only does a deficiency of oxygen induce acapnia, but that acapnia in turn tends to intensify

the deficiency of oxygen, for it depresses respiration and renders the blood less ready to give up oxygen to the tissues. The relation between anoxia and acapnia is thus the heart of the problem of asphyxia. Oxygen is an essential food, but not a stimulant. Carbon dioxide, on the contrary, is a tonic and a stimulant a stimulant that now annually saves thousands of lives.

The author, so your reviewer believes, successfully explodes the theory that asphyxia is essentially a state of acidosis by presenting evidence that carbon-dioxide administration is beneficial in asphyxia and harmful, or even lethal, in true acidosis, such as one induced by the administration of a mineral acid. The terms acidosis and alkalosis, or alkali reserve, moreover, are inherently confusing because without further description of the state named there is great difficulty in knowing what is meant by them. A lowered pH of the blood does not of necessity mean that an acidosis exists that must be combated by alkali. It may be one that can be successfully relieved by acid in the form of carbon dioxide. The pH of the blood is not an inherent quality, it is imposed upon the blood by the volume of the breathing at the moment. Excessive ventilation of the blood in the lungs induces a pH above normal, depressed ventilation a pH below normal. "High and low pH do not indicate alkalosis and acidosis. They indicate only the activity of respiration in comparison with the amount of alkali in use in the blood.

The activity of respiration is determined by the activity of the respiratory center, which controls it. Furthermore, the activity of the center is determined not merely by the stimulus applied to it, but by its own level of excitability. The latter can be altered through a variety of agencies, some of which, notably oxygen want, also pain, fever, alcoholic intoxication and the excitement stage of ether anesthesia, increase excitability, while others, such as sleep, high oxygen and morphine, depress it.

With regard to the amount of alkali in use in the blood, the author claims that, when carbon-dioxide tension in the lungs is increased, alkali is called into the blood from the tissues, and vice versa. This shift between blood and tissue with respect to base under the control of carbon-dioxide tension is an important part of his conception of the physiology of breathing. Oxygen want, he avers, first alters the excitability of the respiratory center, respiration then by overventilation throws the relation of  $\text{H}_2\text{CO}_3$   $\text{BHCO}_3$  in the blood out of balance, and the tissues, through a shift of alkali, restore the balance.

Following the chapters on the physiology of breathing is a series of chapters on pathologic states and their treatment in which the breathing is importantly concerned. Mountain sickness and acclimatization to high altitude come first, then carbon monoxide asphyxia. With regard to the latter the author has proved beyond doubt that the liberation of carbon monoxide from the blood and, consequently, recovery from asphyxia are more rapid when the poisoned subject breathes either air or oxygen, preferably the latter, enriched with carbon dioxide than when he breathes oxygen alone. The hyperpnea induced by the carbon dioxide leads to a far more rapid blowing off of carbon monoxide than does the inhalation of oxygen alone, and the high tension of carbon dioxide permits the hemoglobin to combine readily with oxygen and thus aids in the relief of asphyxia.

Through the development of the H. H. Inhalator and its addition, on a wide scale, to the equipment of the rescue crews of city fire and police departments, city gas and electric companies, hospital ambulances and mine rescue crews adequate resuscitation methods from carbon monoxide asphyxia have been made available to most persons likely to be afflicted.

Asphyxia neonatorum and resuscitation therefrom next

successfully complete the Part I examination proceed automatically to the Part II examination held later in the year.

Applications for admission to the Group B, Part I, examination must be on file in the secretary's office not later than October 4, 1939.

The general oral and pathological examinations (Part II) for all candidates (Groups A and B) will be conducted by the entire board, meeting in Atlantic City, New Jersey, on June 7, 8 and 9, 1940, immediately prior to the annual meeting of the American Medical Association to be held in New York City from June 10 to 14, inclusive.

Applications for admission to the Group A, Part II, examination must be on file in the secretary's office not later than March 15, 1940. For further information and application blanks, address Dr. Paul Titus, secretary, 1015 Highland Building, Pittsburgh (6), Pennsylvania.

### 'CARLO FORLANINI' SCHOLARSHIPS

The International Union against Tuberculosis announces that six scholarships for advanced study in tuberculosis at the 'Carlo Forlanini' Institute in Rome have been made available to the Union through the Italian Fascist National Federation.

These competitive scholarships, of a value of 2000 liras, respectively, plus board and lodging, are intended to enable foreign medical practitioners to stay at the Carlo Forlanini Institute in Rome for the purpose of following a course of studies. This stage of eight months will correspond with the academic year (from November 15 to July 15) including the usual holiday periods. The scholars will reside at the Institute.

The scholarships will preferably be awarded to young physicians who are already familiar with tuberculosis problems and who wish to improve their knowledge of this branch of medicine.

The kind of work undertaken at the Institute will be subject to an agreement between the director of the Institute and the candidate.

Papers resulting from this work must be submitted for publication in the first instance to the editor of the *Bulletin of the International Union against Tuberculosis*.

The scholarships will be awarded at the next session of the Executive Committee which will meet in Berlin in September, 1939. The names of candidates, accompanied by particulars as to their age, qualifications and professional experience, must be forwarded to the Secretariat of the Union, 66, boulevard Saint Michel, Paris (6<sup>e</sup>), not later than July 15.

No candidature shall be taken into consideration unless it has been forwarded to the Executive Committee by a government or an association belonging to the International Union.

## CONVALESCENT CARE OF PATIENTS WITH CRANIOCEREBRAL INJURIES\*

DONALD MUNRO, M.D.†

BOSTON

THE care of patients who are convalescing from craniocerebral injuries has been largely empirical. Little attention has been paid to working out its details, and no attempt has been made to correlate the patient's needs with the antecedent injury and the resulting pathologic lesion. After leaving the hospital, the victim is usually told to "take it easy for a few weeks or months," "not to worry" and "not to return to work until he feels up to it." Headaches, dizziness, lack of concentration, easy fatigability, and the like are considered to be the usual accompaniments of the convalescent period. If they last longer than the doctor's patience, these same symptoms then go under the name of "post-traumatic neurosis" and the patient becomes a surgical derelict. While the primary need is for a better understanding of the original lesion caused by the craniocerebral injury, later intelligent oversight of the patient and his family is also requisite if the therapy given during the acute stages is to yield the results that it should.

### THE PRECONVALESCENT PERIOD

The length of the preconvalescent period will vary with the kind of injury, the accuracy of the doctor's diagnosis and the efficiency of his treatment. For example, if the patient has been diagnosed as a case of "concussion" and actually had concussion, he will have no preconvalescent period at all inasmuch as, by definition, the disease is ended with his return to consciousness. On the other hand, if the case has been diagnosed as one of "concussion" but the patient has in reality had a lacerated brain, or has been diagnosed as suffering from a "fractured skull" and really harbors a subdural hematoma, his preconvalescent care will constitute a major part of his treatment. Indeed, in the latter case it cannot be considered as having

ended until after the removal of the blood clot or its fluid equivalent, a procedure which may not be recognized as essential until years after the receipt of the injury.

Broadly speaking, preconvalescence after craniocerebral injuries ends and convalescence begins when the intracranial pressure has remained fixed at normal for an arbitrary period of two weeks. It should be understood, however, that previous to the start of this period all meningeal clots have been removed, all depressed fragments of bone been elevated or removed and no extracranial or intracranial sepsis is present. Two weeks is commonly considered as adequate for any normal wound-healing, provided the local circulation is efficient and the part at rest so that organization can be effected. Surgically clean cerebral injuries or wounds have the same requirements for healing that similar wounds elsewhere in the body do. In cerebral wounds, however, the local circulation is efficient only in the presence of a normal intracranial pressure. When this pressure is high, there is an associated venous congestion and local tissue anoxia. When it is subnormal, my experience convinces me that the patient's water metabolism is affected, that he is dehydrated and that here too the local circulation is inefficient. It is on this basis that the convalescence after craniocerebral injuries is held to begin at the end of a two-week period of constantly normal intracranial pressure, the part being maintained at rest and local organization effected by keeping the patient constantly in bed. Except as the result of tissue deficit or erroneous diagnosis the great majority of patients are symptom-free during this time. If they are not, and meningeal clots and local sepsis have been eliminated by appropriate measures the cause of their symptomatology will usually be found in associated disease processes such as arteriosclerosis, renal disease, impaired circulation, associated brain tumors, syphilis, multiple sclerosis, other injuries and the like.

Presented at a meeting of the Boston Surgical Society, Boston, April 24, 1939.

\*Assistant professor of neurosurgery, Harvard Medical School; surgeon in chief for neurosurgery, Boston City Hospital.

engages the author's attention. He points out that "much of common belief and practice in regard to manual artificial respiration is unsound or even absurd. Compressing the thorax of an apneic baby in which the lungs are still completely atelectatic cannot draw air into them. Gentle insufflation of air and carbon-dioxide mixture will usually start the infant's breathing very successfully."

Concerning postoperative depression, the author emphasizes the role of diminished tonus of the skeletal muscles, especially those of respiration, induced by anesthetics. This leads to diminution in the size of the chest cavity and promotes atelectasis of the lungs. The best way to combat this tendency is to secure elimination of anesthetics as quickly as possible, and this, in the case of the volatile ones, can be accomplished by letting the patient inhale carbon dioxide in suitable concentration.

The chapter on pneumonia seems, to your reviewer, the least convincing in the book. On the theory that atelectasis, the result of poor bronchial drainage, is an important factor in the development of pneumonia, the author again prescribes carbon-dioxide therapy. It is amusing, to the reviewer, that in the treatment of pneumonia we have had recommended both carbon-dioxide treatment to prevent atelectasis and artificial pneumothorax to produce it. In view of the other methods now at hand for the treatment of pneumonia, it is doubtful if either of the aforementioned has any important place in therapeutics.

So-called shock, in which he believed acapnia plays an important role, was one of the first subjects to engage Professor Henderson's attention, nor have the intervening years obliged him to reverse any of his fundamental concepts. Briefly, he believes the condition chiefly due to impaired venous return to the heart, and this, in turn, to decreased tonus of the body musculature resulting from acapnia or, as he now prefers to call it, acarbica. Furthermore, impaired return flow of blood to the heart leads to asphyxia, just as do failure of the heart itself and hemorrhage.

The final chapter is on muscle tonus and artificial respiration. In this he points out that manual artificial respiration is still the most effective emergency method of resuscitation. He also indicates the relation of muscle tonus to the possibility of resuscitation. The atonic thorax cannot be ventilated by any sort of manual manipulation. But tonus can be restored by the inhalation of carbon dioxide mixtures because this gas not only acts on the respiratory center, but also, so the author believes, exercises a strong tonic effect on the skeletal muscles, thus promoting the natural excursion of the thorax, as well as the return flow of blood to the heart when shock is a factor.

Whether all the author's theoretical structure will endure is doubtful. But at least it can be said that he has used his fertile imagination in a truly scientific manner and that he has pursued facts with vast energy. His facts, for the most part, we can accept as well substantiated. His interpretations occasionally leave us wondering. Professor Henderson deserves more credit than is sometimes accorded him, not only for contributing directly to the knowledge of his subject, but for stimulating a vast amount of work by others, and last, but not least, for contributing to humanity, methods which have saved many lives.

The book is thought provoking and instructive. It is worth the while of any physician or surgeon to read it.

*Carbon Monoxide Asphyxia* Cecil K. Drinker 276 pp  
London, New York and Toronto Oxford University  
Press, 1938 \$4.50

This comprehensive monograph, written by a student of the subject for many years, is a scholarly and thorough presentation of the many aspects of carbon monoxide

hazards. It includes chapters on the physiology and biochemistry of the agent, acute poisoning and the problem of aftereffects, what constitutes harmful exposure, statistics and common sources of hazards, the pathology of the condition, the problem of chronic exposure, the treatment of acute exposures, and finally, chemical methods of detection of carbon monoxide in air and in the body.

The significant literature of the subject is covered and an extensive bibliography is appended.

The importance of carbon monoxide asphyxia becomes evident when we remember that annually in the United States nearly 4000 persons die from this cause. The majority of these deaths are suicidal, but accidental deaths are common and frequently due to preventable causes. Whenever organic matter is burned without adequate oxidation, carbon monoxide is produced. So that in addition to inhalation of illuminating and natural gases, hazards arise from motor-exhaust gas, coal or charcoal gas, smoke in conflagrations, blast furnace gas, gas from explosions, and the incomplete burning of illuminating and natural gases due to defective equipment or exhaustion of oxygen.

The author is inclined to discount the last factor, namely the exhaustion of oxygen, but, in the opinion of the reviewer, too many deaths have occurred in small closed rooms in which gas heaters in use were not faulty to leave much doubt that the lack of oxygen was a factor, even though gas flames were extinguished prior to serious consumption of oxygen. The temperature of the rooms and the circumstantial data in such cases make it probable that the deaths were accidental.

Doubt is thrown on the constancy with which the blood remains fluid in carbon monoxide poisoning, but experience of the reviewer in the examination of bodies, even at long periods after death, is that fluid blood will be found. Thromboses in small vessels, as in the brain, may occur, but they are found in persons who have survived the immediate exposure to the gas and are apparently due to local damage to vessels at the sites of thrombosis, that is, are of secondary production.

The somewhat moot question of chronic carbon monoxide poisoning is given thorough study. It is accepted that recovery from the immediate effects of exposures which result in prolonged unconsciousness may be followed by serious effects due to brain anoxia. It is agreed that persons with diseased organs, notably heart conditions, are much more prone to succumb to given exposures to carbon monoxide than are normal individuals. It has been demonstrated that acclimatization to carbon monoxide may result from repeated exposures, and may be associated with an increase of red cells to add to the oxygen-carrying capacity of the blood. The indefinite character of some of the subjective symptoms, such as gastrointestinal disturbances, insomnia, depression, irritability, burning of the eyes, ringing in the ears and palpitation, leads the author to be properly critical of the diagnosis of chronic carbon monoxide poisoning in individuals repeatedly exposed to small amounts of carbon monoxide. That the individuals who complain of these symptoms are frequently neurotics adds to the doubt of a specific relation in many of these cases. Some of the cases which have been reported, however, are recognized as indicating that there is a syndrome associated with long continued exposure to minor amounts of carbon monoxide which is prone to manifest itself in substandard individuals.

The procedures for resuscitation of subjects of carbon monoxide exposure are well covered, with illustrations of the various methods of artificial respiration.

The book is a welcome addition to the literature on an important subject and is highly recommended.

## CONVALESCENT CARE OF PATIENTS WITH CRANIOCEREBRAL INJURIES\*

DONALD MUNRO, M.D.†

BOSTON

THE care of patients who are convalescing from craniocerebral injuries has been largely empirical. Little attention has been paid to working out its details, and no attempt has been made to correlate the patient's needs with the antecedent injury and the resulting pathologic lesion. After leaving the hospital, the victim is usually told to "take it easy for a few weeks or months," "not to worry" and "not to return to work until he feels up to it." Headaches, dizziness, lack of concentration, easy fatigability, and the like are considered to be the usual accompaniments of the convalescent period. If they last longer than the doctor's patience, these same symptoms then go under the name of "post-traumatic neurosis" and the patient becomes a surgical derelict. While the primary need is for a better understanding of the original lesion caused by the craniocerebral injury, later intelligent oversight of the patient and his family is also requisite if the therapy given during the acute stages is to yield the results that it should.

### THE PRECONVALESCENT PERIOD

The length of the preconvalescent period will vary with the kind of injury, the accuracy of the doctor's diagnosis and the efficiency of his treatment. For example, if the patient has been diagnosed as a case of "concussion" and actually had concussion, he will have no preconvalescent period at all inasmuch as, by definition, the disease is ended with his return to consciousness. On the other hand, if the case has been diagnosed as one of "concussion" but the patient has in reality had a lacerated brain, or has been diagnosed as suffering from a "fractured skull" and really harbors a subdural hematoma, his preconvalescent care will constitute a major part of his treatment. Indeed, in the latter case it cannot be considered as having

ended until after the removal of the blood clot or its fluid equivalent, a procedure which may not be recognized as essential until years after the receipt of the injury.

Broadly speaking, preconvalescence after craniocerebral injuries ends and convalescence begins when the intracranial pressure has remained fixed at normal for an arbitrary period of two weeks. It should be understood, however, that previous to the start of this period all meningeal clots have been removed, all depressed fragments of bone been elevated or removed and no extracranial or intracranial sepsis is present. Two weeks is commonly considered as adequate for any normal wound-healing, provided the local circulation is efficient and the part at rest so that organization can be effected. Surgically clean cerebral injuries or wounds have the same requirements for healing that similar wounds elsewhere in the body do. In cerebral wounds, however, the local circulation is efficient only in the presence of a normal intracranial pressure. When this pressure is high, there is an associated venous congestion and local tissue anoxia. When it is subnormal, my experience convinces me that the patient's water metabolism is affected, that he is dehydrated and that here too the local circulation is inefficient. It is on this basis that the convalescence after craniocerebral injuries is held to begin at the end of a two-week period of constantly normal intracranial pressure, the part being maintained at rest and local organization effected by keeping the patient constantly in bed. Except as the result of tissue deficit or erroneous diagnosis the great majority of patients are symptom-free during this time. If they are not, and meningeal clots and local sepsis have been eliminated by appropriate measures the cause of their symptomatology will usually be found in associated disease processes such as arteriosclerosis, renal disease, impaired circulation, associated brain tumors, syphilis, multiple sclerosis, other injuries and the like.

Presented at a meeting of the Boston Surgical Society, Boston, April 24, 1939.

†Assistant professor of neurosurgery, Harvard Medical School; surgeon in chief for neurosurgery, Boston City Hospital.

## THE CONVALESCENT PERIOD

With the wound healed and the patient free of symptoms, convalescent care after any disease is merely a matter of improving the patient's general condition in so far as his make-up and permanent physical deformities permit. Even adequate care, however, cannot be expected to correct symptoms that are traceable to actual loss or destruction of brain tissue, to the effects of scars or sepsis on the cerebrum, or to associated or intercurrent disease processes. Recognition of and adjustment to the deficits, and treatment of the associated and perhaps unrelated pathologic lesions, are easier and more efficient, however, if the convalescent care of the fundamental damage is intelligent and suited to the patient's needs and understanding.

Adequate but not too much rest, and constantly increasing exercise are classic, efficient and reliable methods for accomplishing this end. This holds true for cerebral as well as for any other wounds. However, the method of application differs in the former because of the curious psychologic reaction that the patient and his relatives and friends have toward injuries to the head or brain. As applied to the patient, this takes the form of a loss of initiative and unwillingness to accept responsibility for his own decisions. As applied to the family and friends, it takes the form of a super-solicitude which is fatally enervating and which supplements the patient's loss of initiative. If these factors are overlooked and not counteracted, the patient does not exercise except when it gives him pleasure, his rest is increased out of all proportion to his needs and his general physical condition not only does not improve but actually deteriorates. His relatives and friends and often his doctor are expected to wait on him more and more. This saps his initiative still further. It does not take much of this to produce the habit of invalidism from which it is only a short step to a permanent neurosis, the development of a new subjective symptomatology to rationalize this neurosis and permanent loss of earning power, self-respect and character. Once this succession of events has fairly started, it is almost impossible to interrupt its progress. Our only hope of reducing the numbers of such permanent invalids following craniocerebral injuries lies in its prevention.

The essential elements—the loss of initiative and the associated lack of self-confidence—are apparently due to two factors. One is the conviction in the average person's mind that a brain injury necessarily means insanity, epilepsy, loss of memory and judgment, and permanent invalidism. This, I should suppose, has its roots in the ideas that recognized evil spirits and witchcraft. In line with the medical education that teaches

us to go to bed and stay there in case of serious illness, the patient, in an attempt to avoid these aftermaths, will naturally tend to reduce his activities to the minimum unless urged to do otherwise. Another factor is a loss of confidence in the medical profession. This is due to the fact that it is common knowledge among the laity that doctors not only cannot cure but do not even believe in the reality of symptoms that persist after craniocerebral injury. An individual who is suffering from persistent headaches and who is honestly unable to earn his living on account of his incapacity is not to be put off with platitudes by doctor after doctor and still be expected to keep his confidence in the medical profession. Any well-managed convalescent regime after craniocerebral injuries should be so planned as to eliminate all element of "magic," and so as to ensure the retention by the doctor of the patient's confidence.

Convalescence after craniocerebral injury may be summed up, then, as a period during which an individual whose wounds have just healed needs direction in regard to returning his general physical condition to normal or better. These directions must be conditioned, however, by the doctor's recognition that the most important element in preventing the attainment of this end will be the patient's loss of initiative and lack of self-confidence. Any plan for convalescent care must, therefore, not only provide directions as to physical activity but must embody in them enough applied psychology to prevent the patient from interfering with his own recovery.

The first increase in physical activity comes with the start of the convalescent period, when the patient gets out of bed. This is the first opportunity to prevent him from losing his initiative. To accomplish this, he is directed to get out of bed in accordance with his own schedule. Specifically, the nurse and he are both made to understand that he and he alone decides how long he shall stay up and how long he shall lie down. He is told to govern the length of these periods by the way he feels. Thus, he is to stay up until he is tired, then return to bed and stay there until rested and then get up again. This start is important. It forces the patient to accept the responsibility for his own actions at the earliest possible moment. If he overdoes and develops symptoms, it is his fault, if he is underactive and does not progress, again it is his fault. Alibis and hence the development of rationalizing symptomatology are nipped in the bud.

As his activity increases, he begins to ask about leaving the hospital. This provides the doctor with the second opportunity to counteract loss of in-

native Serious illness in the home is invariably accompanied—in the lay mind at least—by partial to complete limitation of the patient's activity to one floor and the taking of perhaps all meals but certainly breakfast in bed It is equally true that it is impossible to look on an individual as seriously ill or as an invalid when he goes up and down stairs freely and has, as a matter of course, all his meals in the dining-room with his family If the patient can be made to accept, without suspicion, the hospital equivalent of complete activity about his home, the chance of his developing invalidism in these latter surroundings is greatly decreased However, all the patient knows at this time is that he is up and about all day and wants to go home When told that his return home depends on his ability to remain active all day and to take two flights of stairs twice in succession he proceeds to do so at once Thus, he has been persuaded to demonstrate publicly that he is neither physically incapacitated nor an invalid Failure to live up to his own specifications after his return to the community labels him as a fool, a liar or both, and alienates what would otherwise prove to be the harmful sympathy of his family and friends

Before letting the patient leave the hospital, however, he and his nearest relative are told in detail what permanent defects have been produced by his injury It is important to do this at this time, and it is important to include a member of the family in the audience because only in this way can claims to invalidism based on alleged late discovery of a disabling symptom be forestalled At this same interview it is also explained that the patient's further recovery depends solely on his improvement in general strength, that he is the only person who can bring this about and that he can only do it by taking increasingly larger amounts of regular exercise interspersed with adequate rest He is further assured that if he gets overtired he will have symptoms due not to his brain injury, which is healed, but to exhaustion, and that if he loafs he will remain an invalid A simple set of directions is given him These call for out-of-door exercise every morning and afternoon, nine or ten hours in bed every night, a rest period on his back for one hour before the midday and evening meals, regular hours, plenty of water and no medicine There are three prohibitions The first is that he must never again drink alcohol in any form It has been found that alcohol taken after craniocerebral injuries predisposes to convulsions and is abnormally toxic The second is that he must not dive head first into water It is believed that the sudden change from air to water

pressure as applied to the head with the rest of the body still in the air will frequently cause the patient to faint, with resultant drowning The third prohibition is not to go onto high places unless there is provision against falling off if he becomes unconscious Here, too, it is believed that many such patients are more than usually apt to faint under such conditions

With these directions, the patient is sent out "on his own" for a month This is the period that makes or breaks him, especially if he is a manual laborer The ones in this group, regardless of the original injury or its treatment, especially if they belong to the emotionally labile races like the Italians and Irish, are the most likely to be failures During this first month of convalescence, they, like all who are injured by other people's carelessness or while at work, are subjected to influences that have as their object not the promotion of the physical welfare of the victim but rather his cash value Insurance adjusters, lawyers, police, interested friends and relatives, even interested doctors, begin to urge him to develop more symptoms, accuse him of malingering or refuse to accept as genuine symptoms that he knows are real The development of a neurosis, under such circumstances, must be looked on as inevitable and a matter of self-protection If, because of his economic situation he tries to go back to work, he finds that he is expected to return to his original job whether or not it is suitable, and furthermore must start in on a full-time basis If he is unable to do this, he lays himself open to the accusation of loafing and shirking I do not mean to imply that human nature as represented by the injured working man has any fundamental difference from that as represented by the stockbroker, the lawyer or even the doctor There is always a certain irreducible minimum of the population who will seize any opportunity and use any means to feather their own nests I do believe, however, that the percentage of such individuals among patients with late symptoms after craniocerebral injuries is far lower than is generally conceded

If the patient gets through this first month of his convalescence successfully and reports back to his doctor for further instruction, he should be urged to increase his exercise, diminish his rest period and carry on for another month At the end of the second month, he should be able to return to work on a part-time basis in a job that is suited to his new physical capacity and, at the end of another two weeks, be a full-time employee again Furthermore, he should have learned by then that his craniocerebral injury is actually a thing of the past, that his convalescence did bring his general condition back to normal and that

his initiative and self-confidence are as good as they were before his injury

It can doubtless be successfully argued that there have been many patients with craniocerebral injuries who have fully recovered without such detailed convalescent care. I am also fully aware that recoveries even with this regime are not so common as I should like or as is desirable. As long as lacerated brains are diagnosed as concussion, and subdural hematomas go unrecognized for years, attempts to estimate the effects of any method of treatment on the end results of acute craniocerebral injuries are futile. Nevertheless a start must be made, and a therapy, no matter how bad it is, that includes planned care during convalescence is surely better than one that ignores this stage of the illness altogether.

#### SUMMARY AND CONCLUSIONS

The convalescence of a patient who is recovering from a craniocerebral injury should be planned in such a way as to correlate his needs with the

antecedent injury and the resulting pathologic lesion

The preconvalescent period may vary from a minimum of seconds in a properly diagnosed case of concussion to years in a neglected case of unrecognized subdural hematoma

The convalescent period begins after the patient has had a constantly normal intracranial pressure for two weeks

Loss of initiative and lack of self-confidence on the part of the patient are constant accompaniments of a craniocerebral injury. Otherwise such injuries differ in no important way from wounds elsewhere in the body

The convalescent care of patients with craniocerebral injuries should not be of a hit-or-miss type, but must be carefully planned to keep this associated destruction of initiative and self-confidence from developing into a permanent neurosis and spoiling the end result of what might otherwise have been a successful case

## TECHNIC FOR THE SUCCESSFUL USE OF PROTAMINE-ZINC INSULIN\*

WILLIAM S. COLLENS, M.D.,† AND LOUIS C. BOAS, M.D.‡

BROOKLYN, NEW YORK

A TIMELY editorial in a recent number of the *Journal of the American Medical Association*<sup>1</sup> calls attention to the fact that all is not so well with the use of protamine-zinc insulin, and that the untoward effects of this agent are becoming steadily more recognized. In a paper describing the advantages and disadvantages of protamine-zinc insulin one of us (W. S. C.)<sup>2</sup> called specific attention to some of its undesirable features and recommended certain precautionary measures in its employment.

This paper is concerned with the presentation of certain recommendations which will aid in taking full advantage of the prolonged effect of precipitated insulin, and at the same time avoid the pitfalls and complications attendant on its use.

Before presenting our recommendations, it is well to review the pharmacologic properties of unmodified insulin and protamine-zinc insulin, especially in relation to their effect in lowering the blood sugar. The injection of a dose of unmodified insulin produces certain characteristic changes in the blood-sugar curve. If it is given

intravenously there occurs a refractory period of almost ten minutes during which the blood sugar remains at a practically stationary level. At the end of this period there occurs a very rapid and precipitous drop in the blood sugar. Regardless of the dose, we have observed that the rate of fall in blood sugar is roughly 17 mg. per unit per minute. The total drop is somewhat but not greatly influenced by the dose of insulin administered. The important difference between a large and small dose lies in the total duration of the insulin effect. The larger the dose, the longer will its effect be manifested. These results are similar in the diabetic patient whose initial blood sugar is abnormally high or low. The use of unmodified insulin by the subcutaneous route produces blood-sugar curves which in their general configuration resemble those following the intravenous administration of insulin.

Protamine-zinc insulin, on the other hand, produces a decided change in the character of the action described above. By virtue of the fact that this precipitated insulin is slowly soluble in blood serum, it obviously is not so promptly available as is the unmodified insulin. Enough experimental investigations of the blood-sugar curve following

From the Medical Department of the Greenpoint Hospital, Brooklyn, New York.

‡Assistant visiting physician, Greenpoint Hospital.

the administration of protamine-zinc insulin have been reported<sup>3</sup> to indicate that its full effect is not manifested before the seventh or eighth hour after its administration

Because of the slow liberation of the molecule of insulin from its precipitated form, the duration of the insulin effect becomes definitely prolonged. Thus as it is at present commonly employed, protamine-zinc insulin, in order to be made therapeutically effective during the prandial state, must be given in a dose so large as to be effective during the prandial period of the following day. The chief difficulty in the use of protamine-zinc insulin appears to lie in the fact that the lasting action of the drug has the effect of producing a hypoglycemic state during the postabsorptive period, which lies between 2 a. m. and 8 a. m. This has been borne out by our own clinical experience that the commonest period during which patients have hypoglycemic attacks from protamine-zinc insulin occurs between four and seven in the morning.

It is well in passing to state that the clinical picture of insulin overdosage following the use of protamine-zinc insulin is vastly different from that produced by unmodified insulin. The former is usually characterized by manifestations associated with functional disorders of the central nervous system, such as drowsiness, headache, listlessness, diplopia, aphasia, fatigue, nausea, paresthesias and marked emotional crises, such as crying spells, shrieking, transitory depressions and coma. The well-known shock symptoms which follow overdosage of unmodified insulin such as trembling, pallor, sweats and hunger seem to be curiously absent.

The experience of a hypoglycemic attack must be looked upon as a serious and harmful episode notwithstanding its occasionally trivial and transient character. Baker and Lufkin<sup>4</sup> have observed multiple petechial cerebral hemorrhages in animals that died following a long-standing insulin hypoglycemia. Many reports in the literature have seemed to prove that insulin shock in the elderly diabetic patient is attended by such vascular effects as spasm or thrombosis of cerebral arteries and coronary arteries.<sup>5</sup> Pathologic changes in the electrocardiogram have been reported during periods of insulin hypoglycemia.<sup>6</sup>

We must at this point call attention to an extremely important phenomenon in connection with hypoglycemic states. In the investigation of fasting blood sugar determinations on patients treated with protamine-zinc insulin, we have not infrequently observed blood sugars as low as 40 mg per 100 cc in a patient entirely without symptoms. The dangers in the use of protamine-zinc insulin thus become obvious if the hypoglycemic

state can exist in an individual free of subjective or objective clinical manifestations of this condition.

From our experience with the use of protamine-zinc insulin in 375 diabetic patients over a period of almost two years, we have established a technic which we find to be successful. With our procedure we are able to secure the maximum efficiency of the agent and at the same time avoid untoward reactions. It is our belief that many reports in the literature which have a tendency to discredit the clinical value of protamine-zinc insulin are due to a faulty technic.

#### TECHNIC

There are several factors to be considered in the proper use of protamine-zinc insulin. They are as follows:

##### *Selection of Patient*

If a diabetic patient is receiving one dose of insulin a day, is living on a diet sufficient to meet with the physiological requirements, is free of sugar in his urine and his blood sugar is close to the normal range, we consider him adequately controlled and not a candidate for protamine-zinc insulin. When, on the other hand, the diabetes is severe enough to warrant the use of two or more doses of insulin a day, protamine-zinc insulin should be employed. This statement, however, is made with a slight reservation. Since the elderly, sclerotic diabetic patient is susceptible to serious clinical complications arising from vascular spasms, we think that the hypoglycemic state in these cases must under all circumstances be avoided. Thus the elderly diabetic patient is generally not a suitable subject for protamine-zinc insulin.

In summary, we find that the patients in whom protamine-zinc insulin produces the best results are those between the first and fourth decades with severe diabetes requiring more than one dose of insulin a day.

##### *Insulin*

Our method of using protamine-zinc insulin is based on the following principle. Since several hours elapse after the injection of the drug before its pharmacologic action becomes manifest, and since its effective use comes during the postabsorptive period of the same day and the prandial state of the following day, we have found that the safest way in which to use protamine-zinc insulin is to resort to the administration of unmodified insulin for the production of the insulin effect in the prandial state, and to depend on protamine-zinc insulin for its blood-sugar-lowering effect during the postabsorptive state. Stated in different terms, twenty-four hours after the administration of

protamine-zinc insulin the patient should be recovering from an insulin effect. In order to carry this out in practice it becomes necessary to aim to give minimal doses of protamine-zinc insulin, and to resort to the use of unmodified insulin for the care of the immediate prandial period. We have found in practice that when a patient's total insulin requirements are greater than 20 units a day, an additional injection of unmodified insulin should be given. In the successful use of insulin in our cases, producing maximum insulin efficiency with minimal episodes of hypoglycemia, we cite the following typical combinations of doses which different patients take:

PROTAMINE-ZINC INSULIN units	UNMODIFIED INSULIN units
20	5
20	10
25	10
25	15
30	15
40	15
40	20
40	30
40	40
50	40
60	40

In other words, the dose of protamine-zinc insulin best suited to most of our patients varies between 20 and 60 units, depending on the severity of the disease. If the patient needs more than 20 units, the additional use of unmodified insulin is resorted to. The dose of the latter varies between 5 and 40 units. The preferable time to administer either or both types of insulin is in the morning before breakfast.

It is important to instruct the patient not to mix the unmodified and protamine-zinc insulin when both preparations are to be taken. They should be given in two separate injections, one following the other and in different sites. The reason for this is that, since insulin is precipitated by protamine in an alkaline state, and the reaction is so adjusted in a protamine-zinc insulin preparation, its addition to commercial unmodified insulin, which is an acid solution, has the effect of returning it to a soluble form, thus vitiating the benefits of the precipitated insulin.

#### DIET

The determination of the diet from the standpoint of its total caloric value or its various components of carbohydrate, protein or fat is beyond the scope of this paper. The important consideration in the diet in relation to our suggested method for the employment of protamine-zinc insulin is that half the total carbohydrate should be divided between breakfast and lunch. The other half should be distributed between the evening meal and the intercal feeding. In practice we find that the following proportions are optimal: breakfast, 25 per cent, lunch, 25 per

cent, dinner, 20 per cent, intercal feedings, 30 per cent.

We stress the use of intercal feedings as being one of the most important factors in the proper management of the diabetic patient receiving insulin therapy. These feedings when properly timed have the effect of furnishing the patient with carbohydrate at a time when he is under a maximum insulin influence and is susceptible to hypoglycemic attacks. Knowing that unmodified insulin has an immediate and profound effect, patients are very susceptible to hypoglycemic attacks two or three hours after its injection. Thus the administration of 15 gm. of rapidly absorbable carbohydrate in the form of orange juice or any other fruit given two hours after the insulin protects the patient against a hypoglycemic attack. Lunch should be given exactly four hours after breakfast, followed by another intercal feeding about three hours later. A third such feeding should be given just before retiring, and should consist of carbohydrates and also some protein from which the carbohydrates are slowly made available. Thus a practical feeding schedule consists in the distribution of the carbohydrates in the following way:

TIME	MEAL	PER CENT OF TOTAL CARBOHYDRATE IN 24 HOURS
8 a. m.	Breakfast	25
10 a. m.	Intercal feeding	7
12 noon	Lunch	25
3-4 p. m.	Intercal feeding	7
6 p. m. (later if possible)	Dinner	20
11-12 p. m.	Postcal feeding	15

#### FOLLOW-UP CARE

The subsequent management requires that the patient examine his urine every morning on arising and every evening before dinner. Visits to the physician should be made at monthly intervals. The patient should come prepared with a fractional collection of urines of the previous twenty-four hours. This is a great advantage over the old method of examining a mixed twenty-four-hour sample. The investigation of the fractional urines will disclose the time when the patient is excreting sugar and the time when he is not. The different time periods in the pharmacologic action of protamine-zinc insulin and unmodified insulin being known, it is obvious that the period of the insulin effect should be established with fractional urine examinations. These fractional specimens need not have any relation to the feedings, but should be those that the patient voluntarily voids at all times in the twenty-four-hour cycle before his visit. The fasting blood sugar should be determined at this time. The information obtained from both the fasting blood sugar and the fractional twenty-four-hour specimens of urine will aid materially in determining any alteration in the

dose of insulin. The dose of protamine-zinc insulin is changed according to the blood-sugar findings. An elevation in the blood sugar means that the patient is receiving an insufficient quantity of protamine-zinc insulin. A hypoglycemic blood sugar means that the patient is receiving too much protamine-zinc insulin. The dose of unmodified insulin, on the other hand, is altered depending on the character of the fractional urine estimation. If there is prandial glycosuria, there is of course an indication for an increase of the unmodified insulin. The absence of prandial glycosuria with prandial hypoglycemic attacks requires a reduction in the unmodified insulin.

#### TREATMENT OF HYPOGLYCEMIA

Hypoglycemic reactions occurring during prandial periods will develop in the intercibal periods if the patient is either tardy with the intercibal feedings, entirely neglects to take them or is receiving too much unmodified insulin. These reactions are easily controlled by means of an immediate feeding of a soluble carbohydrate such as 120 cc of orange juice to which two teaspoonfuls of sugar have been added. The patient will then be completely relieved of his attack and will have no further difficulty, for his feedings will protect him against an immediate recurrence. The picture, however, of hypoglycemia which occurs during the night is vastly different, for it is the result of the action of protamine-zinc insulin. The immediate administration of rapidly absorbable carbohydrate will have the effect of relieving the attack, only to have the hypoglycemic symptoms return within an hour or an hour and a half. This is because the carbohydrate has already been consumed and the protamine-zinc insulin is still producing its profound action. The treatment of the protamine-zinc insulin hypoglycemia should in this case consist of feeding rapidly absorbable carbohydrates every hour after the attack until the physician is certain that the patient is over his insulin effect. This may last as long as from four to six hours. Under these circumstances all insulin should be discontinued until traces of sugar have appeared in the urine.

#### TREATMENT OF BROKEN CARBOHYDRATE TOLERANCE

It is a well-known fact that the development of any infection in a diabetic patient is characterized by a marked reduction in insulin efficiency and results in a rapid break of his carbohydrate tolerance. This peculiar vulnerability of insulin activity to the presence of infection appears to be more marked in cases where protamine-zinc insulin is employed. This inactivation of protamine-zinc insulin by infection has been experimentally

demonstrated by Himwich and Fazekas<sup>7</sup> and we have observed the same phenomenon clinically. Where the break in tolerance becomes severe, it is advisable to suspend temporarily the use of protamine-zinc insulin and resort to multiple injections of unmodified insulin until the period of infection has passed. If, on the other hand, the break in tolerance is only mild, adequate control can be established by increasing both modified and unmodified insulin in the morning and giving an additional dose of unmodified insulin before the evening meal. It is advisable that fractional urines be examined during the entire period of the break in tolerance.

#### TECHNIC FOR TRANSFERRING THE PATIENT FROM UNMODIFIED INSULIN TO PROTAMINE-ZINC INSULIN

There appears to be considerable fear in the minds of many physicians regarding the transfer of patients who have been on a regime with unmodified insulin to one of protamine-zinc insulin. Observers have frequently recommended a period of hospitalization in order to effect this transfer. We do not find this procedure necessary under any circumstances. The transfer can be easily performed in ordinary office practice. If a controlled patient is taking up to 20 units of unmodified insulin a day in divided doses, it is possible to give him 20 units of protamine-zinc insulin in one dose before breakfast. If, on the other hand, his diabetic control is established with over 20 units of insulin a day, we recommend the additional employment of unmodified insulin. Transfers may be effected according to the following schedule:

PREVIOUS TOTAL DOSE UNMODIFIED INSULIN units	NEW DOSE	
	UNMODIFIED INSULIN units	PROTAMINE ZINC INSULIN units
20	0	20
30	5	20
40	10	25
50	15	30
60	20	30
70	25	35-40
80	25	40-50
90	30	40-50
100	35	50-60

It is important to remember that the dietetic suggestions which we have recommended, especially in so far as the use of intercibal feedings is concerned, should be rigidly followed. It is suggested that fractional urine samples be examined daily for approximately one week before the stabilizing dose of protamine-zinc insulin is established. The fasting blood-sugar level should be determined once a week for the first month after the transfer.

#### CONCLUSIONS

A technic for the successful employment of protamine-zinc insulin is described, whereby it is

possible to exploit all the benefits of protamine-zinc insulin and at the same time prevent its undesirable side effects. We recommend the use of this agent as a far-reaching advance in the treatment of diabetes.

## CHIARI'S SYNDROME IN A PATIENT WITH POLYCYTHEMIA VERA\*

### Report of a Case

MARK D. ALTSCHULE, M.D.,† AND GEORGE WHITE, M.D.‡

BOSTON

**O**CCCLUSION of the hepatic veins due to thrombophlebitis is uncommon, but when it occurs it produces a well-defined group of signs and symptoms. Although the earliest recorded case of this symptom-complex is that of Budd,<sup>2</sup> Chiari's<sup>4,9</sup> more complete studies in 5 patients seen in his clinic forty to fifty years later have led to the connection of his name with the syndrome. As has been pointed out in the reviews by Hess,<sup>9</sup> Thompson and Turnbull,<sup>19</sup> Satke<sup>16</sup> and Hutchison and Simpson,<sup>10</sup> the hepatic thrombophlebitis responsible for the clinical picture may be either primary or secondary to a variety of lesions situated at the junction of the hepatic veins and inferior vena cava. These lesions include neoplasm, hydatid cyst, gumma, nonspecific inflammatory masses, chronic perihepatitis and cirrhosis of the liver.

The occurrence of this symptom complex in polycythemia is extremely rare. One case was described by Oppenheimer<sup>15</sup> in 1929, since then 7 others have been reported.<sup>2,5,12-14,17,20</sup> Of the 8 cases of the syndrome thus far described, the hepatic thrombophlebitis occurred alone in 5,<sup>2,12-15</sup> in association with thrombophlebitis of other abdominal viscera in 2<sup>5,17</sup> and as a complication of cirrhosis of the liver in 1.<sup>20</sup>

Because of the rarity of the syndrome, it has been thought desirable to report the following case.

### CASE REPORT

C S (B I H 41557), a 27 year-old American white married painter, entered the Beth Israel Hospital on May 20, 1938, complaining of swelling of the legs of 1 week's duration. The family history was negative except for tuberculosis in one brother. The past history revealed the usual childhood diseases, frequent head colds and an episode of diar-

rhea lasting several days 3 years before admission. The present illness began 3 weeks before entry with sudden onset of dizziness, epigastric distress, a sensation of warmth and malaise. A physician told the patient he had the grippe. His fever and malaise subsided in 3 or 4 days. A week before admission he developed severe pain in the flanks which lasted for about a day. Three days later his abdomen and ankles became swollen.

Physical examination on admission was negative except for dullness and diminished breath sounds and fremitus at the right lung base posteriorly, shifting dullness and fluid wave in the abdomen and moderate pitting edema of the legs. Ophthalmoscopic examination showed only moderately engorged veins. The blood pressure was 115/80.

The red blood-cell count fluctuated between 6,760,000 and 6,890,000, with a hemoglobin of 121 to 132 per cent (Dare). The white blood-cell count ranged between 11,000 and 21,000, with 71 to 91 per cent polymorphonuclears. The hematocrit was 64 per cent, and the platelet count 2,000,000. Four urine examinations revealed a maximum specific gravity of 1.024. All other urinary findings were negative except for the presence of bile. A small amount was noted on the day of admission, this increased during the next week. Five stool examinations were not remarkable. The blood nonprotein nitrogen was 45 mg. per 100 cc. on admission, fell to 35 mg. 2 days later and then rose to 100 mg. The icteric index on admission was 6 and rose steadily to 30, at which time the serum bilirubin was 4.2 mg. per 100 cc. The serum protein concentration was 5.8 gm. per 100 cc. The serum cholesterol was 135 mg. per 100 cc. on two occasions, with a cholesterol-ester value of 37 mg. Blood Hinton and Kahn reactions were negative. The venous pressure was 10 cm. by the direct method, and the arm-to-tongue decholin circulation time was 12 seconds. A galactose tolerance test revealed excretion of 1.03 gm. after the ingestion of 30 gm. The total extracellular fluid volume on May 23, as calculated by the method of Crandall and Anderson,<sup>6</sup> was 24.7 l., a value approximately 40 per cent higher than normal for his body build.\* An electrocardiogram on May 25 was normal.

X-ray examination of the heart and lungs was not remarkable except for elevation and diminished respiratory movement of the right dome of the diaphragm.

The pitting on pressure of the tissues of the legs was not elicited after the 2nd hospital day. An abdominal

‡House officer in pathology, Beth Israel Hospital.

\*The actual excess water available for the solution of sodium thiocyanate was 6.6 l. This includes the total excess extracellular fluid and the excess fluid of the blood. Subtracting the probable excess fluid in the blood due to the hypervolemia of polycythemia, the figures indicate approximately 6.0 l. of edema fluid.

paracentesis was performed on May 23, with the removal of 1800 cc. of clear yellow fluid. The specific gravity of the fluid was 1.015 and the protein content 2.8 gm per 100 cc. Following paracentesis the liver was found to be tender and enlarged several centimeters below the costal margin. The spleen was also palpable 3 cm below the costal margin. Two days later painful tender nodules were noted along the course of the veins of the right calf. Distended veins appeared over the lower thorax anteriorly and the upper abdomen. At this time a visiting physician suggested the diagnosis of thrombophlebitis of the iliac veins, of the inferior vena cava below the level of the kidneys and of the portal vein, all probably associated with polycythemia vera. The temperature, which had been normal during the first 7 days, commenced to rise. The patient lost all desire for food, commenced to vomit, developed moderate jaundice and rapidly became comatose. He died on the 9th day.

**Postmortem Examination (A-38-46)** This was performed half an hour after death. The peritoneal cavity contained approximately 500 cc. of clear, deeply bile stained fluid. The liver was slightly enlarged, the lower edge extending 2 cm below the costal margin; it weighed 2140 gm. The greater portion of the right lobe was swollen and poorly demarcated. The caudate lobe was anomalous, appearing as two curved finger like masses. There were some old fibrous adhesions between the under surface of the right lobe and the duodenum, elsewhere the capsule was smooth and glistening. Sections through the liver revealed the previously described swollen portion of the right lobe as consisting of a fatty yellowish tissue poorly demarcated from the normal brownish red liver tissue in the rest of the lobe. The entire caudate lobe showed the same swelling and fatty changes, but the left lobe was apparently not involved in the degenerative process. Approximately three quarters of all the liver tissue shared the degenerative changes grossly. In the right lobe, a little below the capsule, there were found two irregular sharply defined firm, yellowish white, smooth, somewhat hyaline masses, each about 2.5 by 1 by 1.5 cm. These appeared to be healed infarcts. The hepatic veins in the entire right and caudate lobes were thrombosed, all the small and medium sized branches being involved. The thrombi in the smaller peripheral veins completely occluded the vessel lumens, and were adherent to the walls. All were red, and in most cases soft in consistence; a few were firm and apparently organizing. In the larger, more proximal veins the thrombi were a deeper red and soft. Although most of these larger vessels were completely occluded by the thrombi, an occasional vein showed only partial occlusion with thrombi which were not firmly attached to the vessel wall. The thrombotic process was continuous from the smaller vessels to the entrance of the hepatic vein into the vena cava, a small thrombus occurring also in this latter vessel, but not occluding it. The thromboses in the right lobe were situated in areas of necrosis and in the remaining normal-appearing areas. None were found in the left lobe of the liver. The intra-hepatic and extrahepatic bile ducts were not remarkable. The branches of the portal vein within the liver were entirely free of thrombi and not unusual.

There was marked dilatation of many of the branches of the portal veins outside the liver, particularly those in the mesentery of the small intestine. Many dilated veins were also found on the peritoneal surface of the anterior abdominal wall. The inferior vena cava was not dilated and, except for the area about the insertion of the hepatic veins, was free of thrombi.

The spleen was greatly enlarged, weighing 980 gm. It

was dark purplish red and firm in consistence. Sections through the spleen revealed a congested pulp.

The other gross findings consisted of congestion of the lungs and a deep purplish red, cellular bone marrow.

Many sections taken from representative portions of all lobes of the liver, including the areas which grossly appeared to be unaffected, revealed essentially the same process, varying only in intensity. The process consisted of central necrosis and degeneration, so extensive in some areas that the necrotic areas were confluent, leaving only scattered small areas of relatively normal liver cords around the portal spaces. In the zone between the necrotic and intact areas, the liver cords showed degenerative changes with granular deposition and vacuolization within the cell cytoplasm. Inflammatory cells, predominantly lymphocytes and some polymorphonuclear neutrophilic cells, infiltrated these areas of necrosis, and slight hemorrhage was present in a few places. The stroma was better preserved and, in some lobules, showed condensation, bringing the portal areas in closer proximity than is usually found. Fibrosis was noted in only one area. The capsule of the liver was irregular and slightly thickened, with slight fibrin deposition and a few red blood cells on the surface. Bile pigment was found in the canaliculi, the latter showing no evidence of distention. Pigment deposits were also noted in the areas of necrosis. Most of the central and large hepatic veins in all the sections of liver were completely thrombosed. In scattered areas where hepatic veins were seen to be giving off branches it was apparent that the thrombi in the large vessels were older and appeared to be propagating themselves into the small veins. The extent of the liver necrosis varied as the number of vessels thrombosed. Some of the thrombi appeared to be loosely bound to the vessel wall by fibrin meshes, while many showed advanced states of organization with endothelial proliferation, most of them were made up of red blood cells, a few white blood cells and fibrin. There was a notable absence of platelets, and no lines of Zahn were noted. While the majority of the thrombi were of the red variety, a few of the mixed type were noted. The walls of the veins involved were edematous, infiltrated with fibrin and contained variable numbers of inflammatory cells. The portal veins, in contrast, were free of thrombi, definitely dilated, and in most instances filled with serum containing a few cells. A few of the portal veins were packed with red blood cells. The principal lesion consisted of widespread thrombosis of the hepatic veins and small tributaries, with extensive necrosis of the liver substance.

The lungs showed generalized vascular congestion. Small patchy areas of pneumonia were scattered about, while many small bronchi were filled with pus. Areas of emphysema adjoining small atelectatic patches were found near the pleural surfaces. All sections of the lungs contained a few small veins and an occasional artery which showed thrombosis, in various stages of organization, most of them were, however, recent. Only one of these thrombi showed recanalization. Some of the small arteries showed endarteritis.

The spleen displayed marked congestion with increased fibrous tissue in the pulp. A slight eosinophilia was present. The kidneys exhibited the earliest stages of arteriolar sclerosis, with hyaline patches noted in the walls of the afferent arterioles. The kidneys and adrenals were congested. The prostate showed hyperplasia of the epithelial elements. The bone marrow had an increased number of islands of normoblasts; a few collections of myeloblasts were also noted. The other organs were all essentially negative.

## DISCUSSION

The clinical picture of thrombophlebitis of the hepatic veins is fairly well defined. Thompson and Turnbull<sup>19</sup> have divided the cases into two main groups. In some patients the onset is gradual after a period of premonitory epigastric pain. Ascites and a large tender liver develop, the former recurring after repeated paracenteses, and the superficial veins of the chest and abdomen dilate. Vomiting is common. Jaundice is not prominent. Death ensues in one to six months from slowly progressive hepatic failure. In other cases the course of the disease is shortened to a week or less. Coma and delirium are of frequent occurrence in this group of cases. Rarely, life is prolonged for many years. Hutchison and Simpson<sup>10</sup> described a patient who lived a fairly comfortable life for twenty-five years after the apparent onset of primary hepatic vein thrombosis, dying after exploratory laparotomy.

The development of splenomegaly in this syndrome is due to changes in the dynamics of hepatic flow following hepatic vein thrombosis; these probably also contribute to the development of hepatomegaly. In the normal individual the hepatic artery and portal vein are both afferent vessels, and the hepatic veins efferent. Following closure of the hepatic veins, however, the normal egress of blood from the liver is prevented. Marked portal congestion ensues, with the appearance of splenomegaly and dilated abdominal veins. Some portions of the portal system may actually take over the efferent function. The enlargement of the liver is due largely to engorgement with blood, for at autopsy, after the blood has run out of it, the liver has almost uniformly been found much smaller than normal. In the case here reported, however, a considerable amount of swelling was due to degenerative changes in the liver parenchyma. It is possible that if the patient had lived longer the liver might have become markedly atrophied as in most other reported cases. A similar sequence of events occurs in acute hepatitis.

This syndrome may be confused with cirrhosis of the liver, acute hepatitis or thrombosis of the splenic vein. It is distinguished from the first in many cases by the rapid onset, and in most by a tender, enlarged liver. By the time the spleen becomes considerably enlarged in cirrhosis of the liver, the latter organ is usually quite small and rarely tender. The absence of marked jaundice differentiates Chiari's syndrome and acute hepatitis. Splenic-vein thrombosis may be differentiated by the occurrence of left upper-quadrant pain, frequently of a severe degree. The liver is usually not enlarged and is rarely tender. In the

case here reported the finding of evidence of thrombophlebitis in the legs led to a diagnosis of visceral thrombophlebitis, although the exact site of these internal thromboses was not recognized during life. The early prominence of edema of the ankles in our case was probably due to thrombophlebitis of the veins of the legs.

The widespread occurrence of thrombotic processes may have been associated with the extremely high platelet count found in this patient with polycythemia vera, although it is to be noted that the thrombi contained only a very few platelets. It is impossible to define exactly the sequence of events which led to the development of extensive hepatic-vein thrombosis. It is possible that some localized process in the liver resulted in a purely local thrombosis which, in the presence of a greatly increased tendency toward clotting associated with the blood changes and also the slow blood flow of polycythemia, may have rapidly propagated itself to adjacent areas. As successive portions of the liver parenchyma were involved, secondary centers in which venous thromboses were occurring and from which they were spreading may have been established. It is of interest in this connection that one week before admission to the hospital the patient experienced severe pain in the flanks, possibly due to the development of the infarcts found at autopsy. Three days later ascites appeared and a week later jaundice and acidosis, as the hepatic-vein thrombosis spread and parenchymal degeneration developed.

Although the patient died before chemical studies of the blood could be completed, certain changes were noted. Diminished total cholesterol and cholesterol-ester contents of the blood were found, as in the case described by Sohval,<sup>17</sup> even before the development of clinically appreciable jaundice. These are to be ascribed, as pointed out by a number of authors,<sup>1, 7, 8, 18</sup> to widespread liver cell damage. The rise in blood nonprotein-nitrogen concentration is to be ascribed to the development of the toxic nephritis commonly seen in patients with jaundice and severe liver damage. Jacobson and Goodpasture<sup>11</sup> noted the rapid development of severe acidosis in a case of thrombosis of the hepatic veins observed by them.

The changes in the liver which occur in cases with Chiari's syndrome resemble those found in the liver in those with severe congestive heart failure. These changes consist in marked engorgement of the sinusoids of the liver, with degeneration and necrosis of the liver cells in the central portion of the lobule. The involvement of each lobule in the degenerative process is much more extensive in Chiari's syndrome than it is in congestive failure, so that, as in the case reported

here, the hepatic picture approaches that of acute yellow atrophy. Most patients with thrombophlebitis of the hepatic veins do not live long enough to develop extensive fibrotic changes in the liver. The patient reported by Hutchison and Simpson,<sup>10</sup> however, lived twenty-five years after the apparent onset of the thrombotic process in his hepatic veins and at autopsy showed central or cardiac cirrhosis of the liver.

## SUMMARY

Chiari's syndrome, thrombophlebitis of the hepatic veins, may be primary or secondary to a variety of conditions, including, as in the case reported here, polycythemia vera. The clinical, blood chemical and pathological findings are described, and the differential diagnosis discussed.

## NATIONAL AND STATE PROGRAM FOR TUBERCULOSIS CONTROL\*

## Presidential Address

FREDERICK T. LORD, M.D.

BOSTON

NOTABLE progress has recently been made in arousing national interest in the adoption of measures for the prevention and control of tuberculosis. Before discussing these matters, it is desirable to consider the problem as it presents itself in the country as a whole.

## TUBERCULOSIS AS A PUBLIC-HEALTH PROBLEM

There has been a consistent decline in the death rate from tuberculosis in the United States from nearly 200 per 100,000 population in 1900 to a probable rate of below 50 for the year 1938. During 1936, for which returns<sup>1</sup> are available, there were 71,527 deaths from tuberculosis a rate of 557 per 100,000 population. With this number of deaths, it may be estimated that there were at least five times this number of living persons with the disease. It ranked seventh among the leading causes of death without regard to age groups, and first in the most useful and productive

period of life, from fifteen to forty-five years of age.

Tuberculosis control is an expensive public-health project. Considering only institutional provision for the disease, the replacement value of land, buildings and equipment for sanatoriums, tuberculosis departments and preventoriums in the country is estimated by the Council on Medical Education and Hospitals of the American Medical Association<sup>2</sup> at \$328,937,777, and the annual maintenance cost for these services at approximately \$75,906,582.

Though its incidence is steadily diminishing, tuberculosis is still one of the most pressing problems confronting the Nation because of its seriousness and its preventable character.

The favorable trend in the tuberculosis death rate throughout the United States is for the most part, to be ascribed on the one hand to improvement in economic status and better housing and dietary standards, and on the other to a diminishing amount of community infection in consequence of education, case-finding and hospitaliza-

\* Presidential address delivered on March 30, 1939, at the annual meeting of the Massachusetts Tuberculosis League, Boston.

tion As these factors are to a considerable extent within our control, there is a prospect of the practical elimination of the disease as a serious public-health problem

#### REGIONAL VARIATIONS IN THE PROBLEM

The varying magnitude of the problem is apparent when political subdivisions are ranked in accordance with the tuberculosis death rates in 1936. Porto Rico heads the list<sup>3</sup> with a rate of 297.9 and is followed by Arizona (274.6), New Mexico (122.0), District of Columbia (106.1), Tennessee (89.6), Nevada (88.0), Hawaii (85.6), Maryland (85.2), Colorado (76.3) and California (76.2). Without mentioning the states in the intermediate group, an enviable position at the bottom of the list is taken by New Hampshire (33.7), Kansas (28.7), North Dakota (24.9), Idaho (24.7), Iowa (23.8), Utah (21.5), Nebraska (18.3) and finally Wyoming (18.0). The Commonwealth of Massachusetts in 1936 was in thirty-second place among the states in the Union. In 1938, there were 1543 deaths from the pulmonary form of the disease, a rate of 34.9. Deaths from extrapulmonary cases numbered 141, a rate of 3.2. The death rate from all forms in 1938 was therefore 38.1.

The tuberculosis death rate is high in the Negro population, in whom the disease ranks second as a cause of death. The problem is in consequence especially serious in the South.

A high death rate from tuberculosis among Spanish Americans and Mexicans living in the United States is partly responsible for the excessively high rates in some of the counties in Texas, Colorado, New Mexico, Arizona and California.<sup>4</sup>

Migration from one state to another plays a part in the uneven distribution of the disease. Such resort states as Arizona, New Mexico and Colorado are in consequence confronted with an especially difficult problem. Interchange between the states of persons with tuberculosis is to a less extent a problem in all parts of the Union.

Adequate tuberculosis control is in large measure an economic problem, inasmuch as it is concerned with standards of living and the application of measures for diminishing the amount of community infection. Financial resources vary widely among the states. Case-finding facilities and hospitalization of the tuberculous are important factors in control of the disease. A provision of at least two beds per annual death is desirable.

The Technical Committee on Medical Care in its report<sup>5</sup> to the National Health Conference at Washington estimates the ratio of beds per annual death for the United States as a whole at 1.15, with variation for individual states from 2.75 to

0.20. Only five states have two or more beds per annual death, and in twenty-six states the figure is less than one. Nine states make no legal provision for sanatoriums. Five of these subsidize care at local institutions, and four make no statewide provision for the hospitalization of patients.

The South with its large Negro population is under a serious economic handicap and makes little provision for tuberculosis control.

#### NATION-WIDE TUBERCULOSIS PROGRAM

Tuberculosis control in the United States falls short of an attainable goal. This is due in part to economic factors and in part to lack of understanding, acceptance and application on the part of the public, the medical profession and official agencies of remedial measures. In communities such as Massachusetts, where the facilities are adequate, the problem is largely educational and for its solution demands more widespread support of the program. In many communities, and especially in the South, the situation is more serious on account of the lack of diagnostic facilities and opportunity for adequate institutional care.

It may be assumed that further substantial progress in tuberculosis control will not be accomplished without the inauguration of a uniform and adequate program throughout the country as a whole. Leadership and financial assistance in the solution of the problem should come from the central government at Washington, leaving the actual operation of the project to states and localities.

A nation-wide program for the prevention and control of tuberculosis was formulated by a special committee of the board of directors of the National Tuberculosis Association, and was approved on June 20, 1938.<sup>6</sup>

At the National Health Conference in Washington, July 18-20, 1938, the Interdepartmental Committee presented a national health program. Only that part of the program dealing with tuberculosis need be considered here. The Technical Committee on Medical Care<sup>7</sup> reported in connection with the expansion of general public-health service the need for a concerted attack on certain specific problems of national health, including tuberculosis. It recommended case-finding, especially by x-ray examination of contacts of known cases, isolation and treatment (usually bed care) of persons with active disease and periodic observation of those with latent or quiescent disease.

A draft of a proposed bill imposing additional duties on the United States Public Health Service with respect to tuberculosis control was presented by Mr. Folks at the meeting of the board of directors of the National Tuberculosis Asso-

ciation, February 11, 1939, and was approved in principle as a working basis for federal provision. It is in substance as follows:

The recommendation is made that measures for the prevention and control of tuberculosis be established, extended and improved in the political subdivisions of the United States, especially in those with high death rates from the disease and those suffering from severe economic distress, that studies, investigations and demonstrations be conducted and that personnel be trained to accomplish these purposes.

To carry out this project, it is suggested that Congress authorize the appropriation of funds to be made available and allotted through the United States Public Health Service to political subdivisions on the basis of the population, extent of the problem, existing facilities and financial needs and in accordance with plans presented by the local health authority and approved by the Surgeon General.

It is suggested further that after consultation with the state and territorial health officers the Surgeon General of the United States Public Health Service be authorized to prescribe the rules and regulations necessary to carry out the plan and that a Division of Tuberculosis Control be established in the United States Public Health Service. The bill suggests for the year ending June 30, 1940, an appropriation of a sum not to exceed \$7,750,000, for the year ending June 30, 1941, of a sum not to exceed \$33,500,000, for the year ending June 30, 1942, of a sum not to exceed \$37,000,000, and for each year thereafter of such sum as may be deemed necessary to carry out the purpose of this act, provided that subsequent to the year 1945 the sum shall not exceed \$17,500,000.

The Wagner Bill (Senate 1620) was introduced to be enacted as the National Health Act of 1939, as an amendment to the Social Security Act to carry out some of the purposes of the National Health Program, outlined at the Washington conference. It recommends the provision of more adequate public-health service, prevention and control of disease, maternal and child-health services, construction and maintenance of needed hospitals and health centers, care of the sick, disability insurance and the training of personnel. It advocates the appropriation of certain sums for public health work and investigation, and grants to states for hospitals and health centers for the control of tuberculosis, among other projects. The provisions of the bill in its wider scope are much the same in principle as suggested by the National Tuberculosis Association with respect to tuberculosis control. In addition, however, the Wagner Bill requires financial participation by the states and provides for federal and local advisory councils.

The sums specified for public health and medical care in the Wagner Bill are to be allotted to political subdivisions on a matching basis, the highest proportion, two thirds, being applicable to the state with the lowest financial resources, and the lowest, one third, to the state with the high-

est financial resources. The expenditure of federal funds would amount to nearly \$100,000,000 for the first year, without any specific sum's being mentioned for mental disease and tuberculosis hospitals, with gradual increases thereafter. With respect to mental disease and tuberculosis hospitals, there is authorized to be appropriated "a sum sufficient to carry out, in respect to such hospitals, the purposes of this title."

Without attempting to pass judgment on the Wagner Bill or to discuss the relative merits of the different phases of the National Health Program, it is obvious that tuberculosis control is one of the most urgent of them all.

A nation-wide tuberculosis program should include the provision of hospital care for all discovered cases needing such care and case-finding, including x-ray examination of those exposed to the disease by family contact.

#### NECESSARY HOSPITAL BEDS

Estimate of the number of necessary hospital beds for patients with tuberculosis is based on the desirable ratio of two beds per annual death. In addition to the beds already available, it is estimated by the National Tuberculosis Association that about 40,000 beds are needed for tuberculosis.

With respect to the recommendation of the Technical Committee on Medical Care at the National Health Conference<sup>5</sup> that in a ten-year period hospital facilities should be expanded by the provision of 360,000 beds in general, tuberculosis and mental disease hospitals, Fishbein<sup>7</sup> has made the criticism that hospitals in the United States have been for the past five or six years from 25 to 35 per cent unoccupied. It is also stated regarding general hospitals of the country in 1938 that 31.1 per cent of the beds were unused.<sup>8</sup>

It should be noted, however, with respect to tuberculosis hospitals, which alone are under discussion here, that in a census<sup>2</sup> covering 92,339 beds for tuberculosis patients there were 13,571 vacancies (14.7 per cent) and at the same time a waiting list of 9854 patients. This unequal distribution in patient load may be taken to indicate regional variation in the pressure for beds.

So far as tuberculosis is concerned, it is obvious that the number of available beds has a wide regional variation and is not high enough in the country as a whole. Nevertheless, before embarking on an expensive building program for additional beds for tuberculosis or other purposes it is of course desirable to determine to what extent existing facilities are or can be made available.

In view of the probable continuance of the decline of tuberculosis as a public health prob-

lem, it is appreciated that the additional beds will not be needed for the project permanently, and that they should be so constructed and located that they can be used later for general or other hospital purposes

There are nearly three beds per annual death of pulmonary cases in public and private sanatoriums in Massachusetts. The ratio in Massachusetts is exceeded in only few states in the Union and is sufficient for present needs

#### CASE-FINDING PROGRAM

In case-finding, the most important method is the x-ray examination of all family contacts of known cases of tuberculosis. The proportion of cases among contacts is larger than it is in any other group. The extent of the case-finding problem in any community may be roughly estimated by multiplying the number of annual deaths from tuberculosis by the number of discoverable cases, using 5 cases per death as the number which can be discovered, and multiplying this result by the estimated number of exposed persons, or 24 per family.

Persons reported as dying of tuberculosis, patients in tuberculosis sanatoriums and those with tuberculosis in the practice of physicians are among the groups to which recourse may be had in the case-finding program, and each case so located may serve as the starting point for the investigation of family contacts.

In Massachusetts, tuberculosis, in all its forms, is among the diseases declared dangerous to the public health and reportable through local boards of health to the State Department of Public Health. An exception, however, is made with respect to the childhood type of tuberculosis, concerning which a report from the local board of health to the department is made only when sanatorium treatment is recommended.

It should be noted that, so far as Massachusetts is concerned, the Department of Public Health has recently promulgated rules and regulations which, when carried out, will put this case-finding program into operation. These revised regulations<sup>9</sup> are in part as follows:

As soon as a diagnosis of tuberculosis has been established, arrangements should be made for the examination, including an x-ray of the chest, of all members of the immediate family and of other persons with whom the patient has been in close contact. If the family cannot afford x-ray examination by a private physician, facilities are available through the various state, county and municipal sanatoriums. Persons with suspicious findings and those who have had contact with a tuberculous patient should be kept under medical observation as long as advised by the physician.

It is fortunate that facilities for this case finding program are already available in Massachusetts. Since 1931, when the state and county sanatoriums were authorized to extend their services by the maintenance of diagnostic outpatient departments at the request of towns or groups of towns, twenty-two extramural consultation clinics have been established. These clinics furnish diagnostic service through members of the staff of the sanatoriums. They are for the most part in outpatient departments of general hospitals, are provided with x-ray facilities and are available for those who cannot afford to pay.

According to the policies<sup>9</sup> of the Massachusetts Department of Public Health, "It is the responsibility of the local board of health to provide hospital care for cases of tuberculosis when needed, and to see that contacts are examined where such examination cannot be made through a private physician."

With abundant facilities available and plans definitely outlined, there should be an improvement in the case-finding program in Massachusetts. A large proportion of the family contacts of patients in the state and county sanatoriums are now examined by x-ray, but the percentage should be increased in some parts of the State.

In some of the municipal sanatoriums, x-ray examination is likewise made of a considerable proportion of the family contacts. But there is need for improvement in these institutions in the extension of the investigation to include all family contacts. Lack of adequate facilities is in part responsible for the incompleteness of the case-finding program. This difficulty can be surmounted by making use of the services of the state and county sanatoriums.

Case-finding in school children has been in operation since 1924. The school program suffers from failure to secure parental consent for the investigation of more than 50 to 60 per cent of the children. The advantages of the finding of tuberculosis in school children are twofold—to the affected child and to the community. Yet these advantages are fully realized only when the investigation includes both children and family contacts. In general, little has thus far been done to round out this part of the program and to examine by x-ray the family contacts of the children with the childhood (hilus) as well as the adult type of tuberculosis.

The examination of a larger proportion of the family contacts of tuberculous patients in the practice of physicians may be promoted by local boards of health through a circular letter to physicians asking for a list of all tuberculous patients under their care during the year, whether or not previously

reported, emphasizing the importance of sputum examination in suspicious cases, calling attention to the availability of the State Bacteriological Laboratory or other approved laboratories, noting the importance of the x-ray in the early diagnosis of the disease and listing the facilities in the State for the x-ray examination of patients and contacts unable to pay

Group investigation in Massachusetts should be extended to include all teachers, medical students, hospital interns and nurses, college students, diabetic patients, and nursemaids and domestic help in homes where there are children

## REPORT ON MEDICAL PROGRESS

### PATHOLOGY

TRACY B MALLORY, M.D.\*

BOSTON

TO REVIEW, in a few pages, progress in pathology, the least specialized and most inclusive division of medicine, is a manifest impossibility. Probably the editor consciously or subconsciously realized this in assigning to a score of reviewers in this series so many of the choicest items on the pathologic bill of fare that little is left to the pathologist save morbid anatomy in the strictest sense and experimental work in fields still devoid of practical clinical application. Even so, the field remains enormous and a purely arbitrary selection must be made. Several subjects stand out as worthy of brief review because the work of several investigators with varying viewpoints and technics has focused closely enough to permit comparison. Progress is not always easy to distinguish from regress, and in the assessment of rival claims it seems most honest to make no attempt to conceal one's inevitable bias.

#### ARTERIOSCLEROSIS

In the last five years there has been in this country a recrudescence of lively interest in the subject of arteriosclerosis. In a series of papers documented by numerous photomicrographs of exceptional clarity, Leary<sup>1-3</sup> has compared in detail human lesions with the experimental ones so readily produced in rabbits by the feeding of diets rich in cholesterol. In the rabbit it can be shown that in the process of cholesterol deposit fibroblasts are stimulated to multiply and to lay down collagen. With withdrawal of the cholesterol from the diet the lipid gradually disappears from the

vessel but the fibrous intimal thickening persists. By such methods every phase of the human disease can be accurately mimicked. Leary feels that he has demonstrated so close a similarity in the lesions in the two species that one is justified in considering them identical in pathogenesis, and on this ground he advances the hypothesis that human arteriosclerosis is dependent on an abnormality of the cholesterol metabolism. He admits, but does not stress, the importance of local vascular phenomena in determining the localization of the deposits. In subsequent communications he has somewhat qualified this conclusion, admitting that the disorder in cholesterol metabolism may be local rather than general.

Duff,<sup>4,5</sup> in contrast, finds slight but undeniable differences between the rabbit and human lesions, particularly in an early involvement of the media in the experimental lesions which is lacking in the human disease. He presents evidence of preliminary degenerative change in the arterial walls before cholesterol is deposited, and believes that hypercholesterolemia alone will not give rise to atheroma. He emphasizes the lack of clinical or extravascular histological evidence of disordered cholesterol metabolism in the human disease except in relation to diabetes, where the disturbance of metabolism is so extensive that many other factors besides the hypercholesterolemia may be responsible for the initiation of the lesion. He calls attention once again to the well-known fact that premature arteriosclerosis has never been experimentally produced by cholesterol feeding or in any other way in omnivorous animals which spontane-

\*Assistant professor of pathology Harvard Medical School director Department of Pathology and Bacteriology Massachusetts General Hospital.

ously develop the disease at advanced ages, and wisely advises caution in applying to man a conclusion which seems self-evident from a study of the artificial rabbit disease

Experimental rabbit atherosclerosis remains, however, a fascinating tool for the investigative pathologist. Systematically the variations are being played, testing, for instance, one after another endocrine gland to determine whether over- or underfunction will accelerate or decrease the rate of development of vascular lesions. To date the most consistent results relate to the thyroid,<sup>6</sup> where hyperthyroidism is generally agreed to delay the appearance of atheroma and hypothyroidism to accelerate and accentuate it—a point not to be forgotten before recommending total thyroidectomy for the relief of angina pectoris. Such substances as thyrotropic pituitary hormone<sup>7</sup> and potassium iodide,<sup>8</sup> the effects of which on experimental atheroma are notably variable, can fairly safely be assumed to act through the mediation of altered thyroid function. Physicians with the requisite philosophy may find complacency in the experiments of Eberhard,<sup>9</sup> who demonstrated that though alcohol ingested along with cholesterol raised the level of blood cholesterol, it delayed the deposit of the lipid in the blood vessels.

A new angle of attack on the problem has been developed and energetically pursued under the direction of Winternitz at Yale University. With various collaborators he has made an extensive study of the vasa vasorum of the aorta and various major vessels, such as the coronary and renal arteries, under normal and pathologic conditions. The results of this work have been summarized in a monograph rather broadly entitled *The Biology of Arteriosclerosis*<sup>10</sup> replete with colored illustrations which support the author's points with convincing clarity and esthetic charm. Conservative in positive statement, it is presented in a manner which permits almost limitless implications. Although vascularization of atherosclerotic plaques has been repeatedly noted by previous investigators, its extent has certainly never been so vividly demonstrated. A critical study of both the illustrations and the text, however, leaves little doubt that the great majority of lesions studied must be classified as advanced and as derived from vessels with long-standing disease. Convincing evidence that in normal human arteries the vasa vasorum extend into the intima, or even with significant frequency into the inner third of the media, is lacking. Under such conditions it is difficult to believe that lesions of the vasa vasorum can initiate atherosclerotic plaques, which all evidence indicates are, primarily, intimal lesions.

The subintimal hemorrhages which the author finds with such frequency by his method of clearing vessels with the Spaltheholz method are of interest and have undoubtedly been neglected by most previous investigators. Though hemorrhages may evidently be invisible beneath a thickened opaque intima, it seems scarcely possible that they could be missed by any method of examination in a vessel with an intima of normal thickness which is almost perfectly transparent. It seems doubtful, therefore, that such hemorrhages can, as Winternitz suggests, be a significant factor in the initiation of atherosclerotic lesions. That they may, however, play a vital role in the disruption of established atheromatous plaques and in the initiation of thrombosis seems more probable. This possibility has been emphasized by Paterson,<sup>11, 12</sup> who found intimal hemorrhages arising, he believes, from the vasa vasorum in 32 of 37 consecutive cases of coronary thrombosis. Continued extensive investigation by a variety of methods will be necessary to establish the validity of this hypothesis as against Leary's theory of the anemic necrosis of the thickened avascular intima. The application of Winternitz's technic to the study of experimental atheroma might go far in answering some of these questions. On all investigators working with human material the importance of establishing adequate criteria for determining the age of the lesions under observation, and the particular importance of studying early lesions should be urged.

#### CORONARY SCLEROSIS AND INFARCTION OF THE HEART

The correlation of infarction of the myocardium with occlusion of the coronary artery is often difficult or even impossible under the conditions of a routine autopsy. All pathologists frequently see thromboses unassociated with infarction, and acute infarcts associated with a vessel so completely fibrosed and calcified that it must have been occluded years before. The existence of collateral circulation has, of course, been inferred in order to get them out of their difficulty. More precise information in regard to this collateral has been accumulating rapidly in recent years. By extreme care and thoroughness in the gross examination of the coronary circulation, Saphir and his collaborators<sup>13</sup> were able to show that infarction of the myocardium rarely develops when a single coronary branch is occluded unless there is simultaneous or pre-existing partial or complete obliteration of other branches as well. An acute infarct, for instance, may be found in the area normally supplied by the descending branch of the left coronary, this vessel will show an old occlusion, but with sufficient care a fresh occlusion can always be found.

elsewhere, perhaps in one of the branches of the right coronary artery which has for years been supplying a collateral circulation. Though collateral circulation may safely be inferred from such observations, it cannot ordinarily be demonstrated by simple methods of gross dissection. A notable advance, therefore, is represented by the recent work of Schlesinger.<sup>14</sup> He uses a new injection mass of agar and lead salts which permits a very uniform injection of the arterial tree down to arterioles of 40 microns in diameter. He has in addition developed a new technic for opening, or rather unrolling, the heart which without cutting across any important vessels enables one to spread out the entire heart in one plane. This enormously improves the radiographic visualization. With this method Schlesinger has found in truly normal hearts no anastomoses large enough to permit the passage of his injection mass. In diseased hearts of various types they are frequently found, and in cases of coronary sclerosis they can be readily demonstrated whenever arteriosclerotic narrowing or occlusion causes obstruction in the coronary circulation. This extensive spontaneous development of collateral circulation should be borne in mind in interpreting the results of operations designed to produce artificially such a collateral circulation.

#### LUNGS

A point of minute anatomy in the lungs which is of great theoretical importance to the pathologist seems finally to have been settled after years of dispute with the histologist. This concerns the existence of pores of Cohn in normal lungs. Macklin,<sup>15</sup> by a study of very thick lung sections in which many alveolar walls were viewed from their flattened surfaces rather than in ordinary sections, was able to show obvious communications between alveoli in various animals and in man. Though present at all ages, they become larger and more numerous with advancing age. Loosli<sup>16</sup> has confirmed this finding by the method of serial sections, in an article documented by photomicrography of exceptional clarity and detail. Their minute size, 5 or 10 microns, explains why they were missed in previous reconstructions. The importance of such interalveolar air channels in explaining the relation of bronchial plugging to atelectasis and the mode of spread of infection throughout a lobe are obvious.

In the field of pulmonary neoplasm, more and more attention is being given by bronchoscopists, thoracic surgeons and pathologists to those peculiar semi-benign bronchial tumors which have generally in this country been called adenomas. It is evident that in some clinics they are even yet not

distinguished from carcinoma. Though locally infiltrative and unquestionably capable of metastasis to regional nodes, their progress is slow and the likelihood of generalized metastasis so slight that they deserve to be sharply distinguished. Attempts to explain their histology have been numerous and unsatisfactory. We and Graham<sup>17</sup> have recently proposed that they are mixed tumors and should be included with hamartomas. Hamperl<sup>18</sup> in contrast points out the remarkable histological and clinical similarity to the argentaffine tumors of the intestinal tract ordinarily called carcinoids. Decision upon a point of pathogenesis must rest primarily upon accurate histologic observation, the first prerequisite of which is good histologic technic. A glance at the photomicrographs accompanying the review would suffice to explain why the reviewer is prejudiced in favor of Hamperl despite the unfortunate failure of all investigators to demonstrate that the cells are argentaffine.

The development by Robertson and his co-workers<sup>19-22</sup> a few years ago of a reliable method of producing pneumococcal lobar pneumonia in the rat has added much to our knowledge of the pathologic lesions of pneumonia. The study of a large number of experimental lesions and their comparison with human material have made it apparent that lobar pneumonia ordinarily starts as a focus of parenchymal infection near the periphery of a lobe. Spread occurs via the air spaces and the pores of Cohn, and Blake and Cecil's<sup>23</sup> theory of lymphatic extension has been supported. Loeschcke<sup>24</sup> from a very careful study of extensive human material had already reached the same conclusions, and his findings are in close agreement with those of Robertson.

In a continuation of these studies Robertson and his associates<sup>25-28</sup> have shown clearly that the course of every pneumonia depends on a dual mechanism: first, a generalized process which acts to localize the infection and prevent or control invasion of the blood stream, and second, a local process by which the lesion itself is finally freed from the organisms. To a large extent these processes appear to be independent of each other. The generalized element is the familiar process of body formation, the local one is a tissue reaction within the lung itself. The outstanding feature of the latter is a macrophage reaction which appears about the fortieth hour even in animals and man. It may eventually succumb to bacteremia. With the onset of this macrophage reaction the lungs rapidly become sterile and pneumococci, if found at all, are almost entirely intracellular. It is possible for such a macrophage reaction to sterilize one lobe while active progression of

fection is occurring in other lobes. The persistence and even occasional extension of consolidation following apparent symptomatic cure by serotherapy are explained by this independence of the two reactions. They will soon have to be carefully evaluated in relation to chemotherapy.

#### TUBERCULOSIS

In no field of pathology is progress more difficult to assess than in tuberculosis, particularly its experimental aspects. Hardly an experiment can be recorded for which in the ensuing years refutations do not outnumber the confirmations. Uncontrolled—perhaps uncontrollable—variations in dosage, virulence, natural host resistance, time of observation, dietary factors and complications of intercurrent disease render the same experiment in two investigators' hands barely comparable. It may be of value to point out some of these conflicting results and so drive home the need of deliberation in the acceptance of any experimental results in this field.

One of the sources of liveliest debate has been the relation of allergy to immunity. Rich<sup>27, 28</sup> and Cannon and Hartley<sup>29</sup> among others, have shown clearly that allergic inflammation fails to localize a virulent pyogenic organism such as the pneumococcus. This of course does not prove that it may not localize tubercle bacilli. Apparently conclusive evidence that also in tuberculosis immunity can be separated from allergy was presented by Rothschild, Friedenwald and Bernstein<sup>30</sup> when they showed that infected animals desensitized with tuberculin showed less extensive tuberculosis two months after re-infection than did allergic animals or normal controls. Although this conclusion was confirmed by Birkhaug<sup>31</sup> and various other investigators,<sup>32</sup> results pointing in the opposite direction were obtained by Willis and his collaborators<sup>33, 34</sup>. In an extensive experiment with over 500 animals they found that when the observations were carried beyond the sixty-day period used by Rothschild et al. the desensitized animals, although developing fewer tubercles in the liver and the spleen, died in large numbers of acute tuberculous pneumonia long before the allergic control animals. In all such experiments the repeated injections of large amounts of tuberculin necessary to keep the animals desensitized provoke fever, anorexia, loss of weight and the death of numerous animals either from shock or intercurrent disease, and the results are almost impossible to interpret. Moreover, the failure to evoke a skin reaction in such debilitated animals is by no means conclusive proof of complete desensitization.

Another subject which continues to be the source of a voluminous literature is the study of the factors underlying the formation of the tubercle and their relation to allergy. Under the aegis of the National Tuberculosis Association an extensive collaborative enterprise involving many laboratories and scores of workers has been centered about the chemical fractionation of the tubercle bacillus and the testing of the various separate and combined fractions histologically and immunologically. Many of the early results proved misleading or contradictory—first, because many of the earlier fractions tested were impure, secondly, because the significance of the degree of allergy was not always borne in mind, thirdly, because quantitative probabilities were not duly considered, and finally, because in the process of purification proteins have probably been chemically and antigenically altered. In Sabin's most recent publications<sup>35-39</sup> many of these conflicts appear to have been resolved. The carbohydrate fraction will not induce sensitivity and gives only an immediate polymorphonuclear type of skin reaction, the waxes provoke only nonspecific foreign-body reactions, the proteins will induce sensitivity and produce either polymorphonuclear or mononuclear response, dependent, as Dienes and Mallory<sup>40, 41</sup> pointed out for proteins in general, on dosage and degree of allergy, the phospholipids produce an accentuated mononuclear response with marked development of epithelioid cells. By combining phospholipid and protein, apparent true tubercle formation is induced and hypersensitivity greatly increased. The amount of phospholipid employed is still far greater than the dissolution of a reasonable number of tubercle bacilli would provide, and the reaction may not be entirely specific. An accentuation of hypersensitivity by the combination of tubercle bacilli or their derivatives with other fats and oils has been noted by Saenz<sup>42</sup> and others. Still more conducive to conservatism in attributing to specific organic chemical factors of the tubercle bacillus responsibility for the development of one or another feature of the exudative reaction is the demonstration by Gardner<sup>43</sup> that every phase of this reaction can be exactly duplicated by the injection of a simple inorganic substance, silicon dioxide.

also associated with tuberculosis. These oval areas of rarefaction which simulate thin-walled chronic cavities are just as likely to be thickened pleural septa with areas of emphysematous lung between.

DR. SHORT: This represents an old process?

DR. HAMPTON: Yes. I think that everything we see in the chest is chronic. This shadow at the right base could be acute consolidation but it is seen in only one film and it is not plain. I do not see how we could make a diagnosis of active disease in his chest.

DR. SHORT: To save time I have decided to admit from the beginning that this patient had an infection with *Bacillus mucosus capsulatus* or Friedländer's bacillus. I can hardly believe that both the blood culture and urine culture represent contaminants, nor, since the blood culture was taken six days before the patient's death, do I think that the former could represent an antemortem invasion of the blood stream by essentially saprophytic organisms. Of course he may have had a combined infection, the picture is suggestive of acute miliary tuberculosis, with indefinite signs and lack of a definite x-ray picture in the lungs, and terminal meningitis. As Dr. Hampton said, there is possibly some evidence of an old tuberculous process in the chest. I do not believe we have enough positive findings to make that diagnosis and, therefore, we have to dismiss it. I do not see that any of the picture represents toxic symptoms from sulfapyridine, although he was given a large dose in the first twenty-four hours. There is no evidence of agranulocytosis or diminished resistance to infection and, surprisingly enough, no mention was made of his vomiting.

The points left for us to decide, then, are the primary source of the bacteremia and the organs of the body which were finally invaded. I think that from the negative x-ray of the chest and the lack of definite signs on physical examination we can rule out a primary pneumonia. The lung findings may represent either an old process, as Dr. Hampton suggests, or possibly an early metastatic infection in the lungs. According to the literature, extrapulmonary infections with this organism are not uncommon. Baehr, Schwartzman and Greenspan\* reported 198 cases from one hospital. Of these, nearly a third resulted from peritonitis following a perforation of the gastrointestinal tract. The next commonest source was the biliary tract or the liver, and the next the genitourinary tract. In these last two, stasis was a factor and there was often a bacteremia. There were very few cases originating in the middle ear or sinuses.

The onset of this patient's illness was certainly not very characteristic. It suggested a head cold until the development of chills and fever. I think a presumptive diagnosis of pneumonia was probably justified from the clinical picture in a man of his age. He apparently had jaundice on admission because of the finding of bile in the urine, although it was not noted in his skin or sclerae until a day or two before he died. I do not believe there is enough evidence for a primary infection in the liver or biliary tract. The jaundice is really the only thing we have pointing in that direction and it could just as well be a toxic hepatitis due to a generalized infection.

Then we come to the genitourinary tract. The patient died with a high nonprotein nitrogen in the blood serum. We are not told anything about the fluid intake or how much he vomited. Probably he did not take in very much in the last few days when he was in coma. The one examination of the urine hardly suggests a urinary-tract infection, but it does not rule it out. Of course, with a generalized infection, the positive urine cultures could be explained on the basis of excretion through the kidneys of the organisms in the blood stream. There is nothing to suggest that this patient had an already existing nephritis. He had a normal blood pressure and fairly good specific gravity of the urine. I shall have to assume that, unless the high nonprotein nitrogen was due to vomiting and dehydration, he did have a renal infection which was severe enough to destroy most of the functioning tissue in his kidneys. This may have been furthered by some unrecognized urinary obstruction, perhaps an enlarged prostate.

Terminally the patient had signs of meningitis. Of course, without lumbar puncture we have no way of knowing that he did not have an extradural abscess which may have given these signs with a sterile spinal fluid. To sum up, I think this patient had a generalized Friedländer's infection with bacteremia, with the primary source undetermined. We cannot say he had a primary pneumonia or primary infection in the biliary tract or liver. There is no real evidence of sinus or middle-ear infection. By elimination, a primary source in the urinary tract is most likely, resulting in a severe pyelonephritis, and finally the development of signs of meningitis.

### CASE 25251

#### PRESENTATION OF CASE

An eighty-three-year-old man was admitted complaining of chills and fever.

Six days before entry the patient noted the onset of a chilly sensation. His head felt big, and he had anorexia. He went to bed early, slept well, but woke the following morning and noticed increased perspiration. He had no appetite and remained in bed most of the day. His nose felt stuffed up, and his head full. Postnasal phlegm, which was worse when he had a cold, had been a chronic complaint for the past several years. His physician saw him on this second day of his illness and found a temperature of 98.6°F and a pulse of 72. There were a few rales at the bases of both lungs. The following day he had a chill followed by a temperature of 103°F and respirations of 30. Physical signs on examination of the lungs were indefinite. There was no pleural pain. The blood showed a white-cell count of 15,750 with 94 per cent polymorphonuclears. The blood pressure was 128 systolic, 60 diastolic. It was assumed that he had pneumonia, and 9.5 gm of sulfapyridine were given at four-hour intervals during the following twenty-four hours. Shortly after completion of this course of therapy he had another chill and his temperature rose to 101.6°F. A few hours later he was again given 2 gm of sulfapyridine, following which his temperature soon fell to 99.2°F. On examination the tongue and soft palate were red. The lungs showed no definite signs except for slight dullness at the right base and a few rales at the left base. Respirations were 30. On the following day he seemed better during the morning but in the afternoon again had a chill with a temperature rise to 101°F. An x-ray film of the chest, taken with a portable machine, showed no evidence of pneumonia. He had not had abdominal pain or tenderness, jaundice or urinary symptoms.

Physical examination on admission showed a well-developed and nourished, acutely ill man. There were a few rales at both lung bases. The blood pressure was 128 systolic, 60 diastolic. No other definite physical signs were noted.

The temperature was 100°F, the pulse 100, and the respirations 27.

Examination of the urine showed a specific gravity of 1.020, a trace of albumin, a slight trace of bile, many coarsely granular casts, rare cellular casts, 3 or 4 white cells and an occasional red cell per high-power field, no bacteria and no sugar. The blood showed a red-cell count of 4,520,000 with 90 per cent hemoglobin, and a white-cell count of 27,400 with 83 per cent polymorphonuclears, 4 per cent small lymphocytes, 11 per cent mononuclears, 1 per cent nucleated red cells and 1 per cent myelocytes. The red cells appeared fairly normal, there were rare polychromatic and stippled cells. The nonprotein nitrogen of the blood serum was 65 mg per 100 cc. Blood cultures showed *Bacillus mucosus capsulatus* (Friedlander's bacillus), as did the urine cultures.

Portable x-ray films of the chest showed a band of linear density extending upward and laterally from the left hilus to the lateral chest wall in the region of the interlobar pleura. There were oval areas of rarefaction just beneath the pleural surface in this area. The lung markings extending to the right base were a little prominent, and there was some haziness just above the midportion of the right diaphragm. There was a large calcified node in the right hilus. The diaphragm was high in position. The costophrenic angles were clear. The aorta was tortuous, and there was calcification in the arch.

The patient had another chill on the afternoon of admission. Sulfanilamide therapy was begun. On the following day his temperature was 103.8°F. There were many rales at the right base posteriorly. On the third hospital day the patient was drowsy and could not be aroused. The right lung was clear, but rales were heard at the left base. The abdomen was negative. There was slight stiffness of the neck. The white-cell count was 32,700 with 96 per cent polymorphonuclears. The temperature was 101 to 103°F. On the following day his neck was stiff and rigid. The left chest was clear, but rales were present on the right. The nonprotein nitrogen of the blood serum was 95 mg per 100 cc. On the fifth hospital day he still could not be roused. His pulse was very weak. There was slight edema of the ankles. The abdomen was slightly distended. There was slight jaundice. His neck remained stiff. He rapidly failed and died on the sixth hospital day.

#### DIFFERENTIAL DIAGNOSIS

DR CHARLES L. SHORT: May we see the x rays?

DR AUBREY O. HAWPTON: These portable films were taken in this hospital. The linear shadows described in the left lung follow the course of the pleura between the upper and lower lobes. You sometimes see them following pleurisy, they are

were guaiac positive. The sedimentation rate was 3 mm in fifteen minutes, 7 mm in thirty minutes, 12 mm in forty-five minutes and 15 mm in sixty minutes.

X-ray films showed a soft-tissue mass about 4 cm in diameter in the left side of the true pelvis. There was fecal material in the bowel, and the right kidney area showed multiple areas of density. An intravenous pyelogram was negative. The lumbar vertebrae showed lateral curvature, apparently due to anatomical variation of the fifth lumbar vertebra and upper segment of the sacrum. There was no evidence of metastatic malignancy in the bone. On the following day, x-ray films showed no change in the soft-tissue thickening in the pelvis. There was more gas in the small bowel on the left side of the abdomen. The loops were definitely dilated, and one extended to the true pelvis. There also was gas in the colon. Although the gas in the small bowel indicated some obstruction, it apparently was not complete.

She did not improve, and on the fourth hospital day an operation was performed.

#### DIFFERENTIAL DIAGNOSIS

DR. OLIVER COPE. I should like to narrow down the diagnosis, if I can, before Dr. Hampton shows us the x-ray films.

A brief review of the history shows a first episode of acute gonorrhea. Seven years later there was a period of abnormal bleeding, a diagnosis was made of carcinoma of the cervix but we are not told anything definite about it. She had x-ray treatment, then radium, with complete relief of the abnormal bleeding and cessation of the menses. In the first month after the irradiation there appeared these transient periods of weakness, occurring frequently, which may have been menopausal symptoms or may have been associated with what appears later. Before she entered the hospital she had a more profound spell of weakness accompanied by pain, and subsequently we find that there must undoubtedly have been an intestinal hemorrhage and also some bowel obstruction. X-ray study gives further evidence of a mass in the left side of the pelvis and of small-bowel obstruction, which is consistent with the history.

The diagnosis has to take in two important things: small-bowel obstruction and intestinal hemorrhage. The physical findings are of importance. At the time of the second admission, when the radium was given under an anesthetic, no mass was felt in the pelvis. The mass shown by x-ray is, therefore, something that has arisen in the past seven months. I shall exclude certain diagnoses very rapidly. In the first place, inflammatory lesions such as appendicitis and diverticulitis should

be excluded on the basis of intestinal hemorrhage. Endometriosis, which occasionally might cause intestinal hemorrhage and may also give small-bowel obstruction, I exclude on the basis of the artificial menopause which had been produced seven or eight months previously. There ought to have been no recurrence of endometriosis, had it been present before the irradiation. I also exclude simple intestinal obstruction in view of the intestinal hemorrhage. In the same way I exclude pelvic inflammation with necrosis following irradiation; I have not seen intestinal hemorrhage under these circumstances. That narrows the diagnosis down to two possibilities: metastatic malignancy from the cervix to the bowel and Meckel's diverticulum or a primary malignant tumor in the small intestine. When we consider metastatic malignancy, I think we can narrow the field still further. I have never seen an ordinary carcinoma of the cervix give rise to intestinal hemorrhage and to small-bowel obstruction—that may be due to lack of experience, an adenoacanthoma, however, does. I have seen one case in which an adenoacanthoma had a secondary lesion in the large intestine with both bleeding and obstruction. I think, therefore, an adenoacanthoma is the most logical way of tying up carcinoma of the uterus and the present symptoms.

If it were not for the history of a lesion in the uterus I should say that the history for which the patient entered the hospital would be best explained by a Meckel's diverticulum. Such a diverticulum characteristically gives bouts of hemorrhage and when acutely inflamed leads to intestinal obstruction. I shall leave it with these two diagnoses, adenoacanthoma and Meckel's diverticulum, until we hear what Dr. Hampton has to say.

DR. AUBREY O. HAMPTON. This patient had an x-ray of the spine and chest for metastases, and none were found. This film was taken on the first day, when she had very little evidence of intestinal obstruction. This was the shadow described on the left side, which was thought to be a round mass. It is not so sharp and distinct as a tumor would be. It could be a loop of dilated bowel just as well. Usually the outline of a cyst or tumor is seen all the way around, but this shadow is only partially outlined. That may be because it is tubular, it could not be circular. This soft-tissue shadow is better seen in the film taken at the time of the intravenous pyelogram examination. We can see the bladder and then a perfectly smooth mass that looks like the uterus sitting on top of it. At this examination two days later we see the small bowel dilated down to the region of the true pelvis. That is evidence enough of dis-

## ANATOMICAL DIAGNOSES

Septicemia, *Bacillus mucosus capsulatus*  
Multiple abscesses of the liver  
Healed pulmonary tuberculosis

## PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY Dr Short has done as well as we could at the autopsy. We could not find the source of infection. We did not have permission to do the head, so one of the accessory sinuses may possibly have provided it. We did do the spinal cord, however, and he had no diffuse meningitis. The most obvious findings at autopsy were multiple abscesses in the liver, the right lobe being almost completely filled with them. It is often difficult with extensive liver involvement to determine the mechanism of infection. Nothing was found, however, to suggest cholangitis or pylephlebitis, so that I believe the organisms reached the liver via the hepatic artery as part of the general septicemia. The lungs were entirely negative, except for extensive healed tuberculosis. The kidneys showed vascular nephritis and the ordinary cloudy swelling due, I am sure, to his fever and toxemia. There was no pyelonephritis, and though the prostate was a little large, it was not hard and did not appear to be obstructing, so I do not think the urinary tract was the source of infection.

## CASE 25252

## PRESENTATION OF CASE

*First Admission* A thirty-eight-year-old widow was admitted complaining of dysuria.

She had noticed burning at the end of micturition of seven days' duration. Frequency and urgency were also noted. Gram-negative intracellular diplococci were found. Diagnoses of cystitis and acute urethritis were made. She was discharged on the eighteenth hospital day.

*Second Admission* (seven years later) Her menses had been normal and regular until four months before admission when she had five attacks of intermenstrual bleeding during one month. Each was somewhat less in amount than that of a normal period. Following this she had daily spotting until three weeks before entry when a diagnosis of carcinoma of the cervix, confirmed by biopsy, was made at another hospital. She received 4500 r of x-ray therapy during the next twenty-one days. After the treatment was begun the discharge changed from bloody to serous. She had continued to have periods at the regular time, the last one twenty-six days before entry.

Physical examination showed a well-developed and nourished woman in no distress. Examination of the chest was negative except for an occasional rale at the right apex. The blood pressure was 120 systolic, 80 diastolic. An apparent x-ray burn was present on the skin of the lower abdomen. Under nitrous oxide anesthesia, pelvic examination showed a 9-cm retroverted uterus which could be replaced. There was apparent submucous extension of the cancer at the external os, but the lesion seemed fairly superficial, a biopsy was taken. Radium needles were implanted, the total dose being 3000 hours. The pathological report on the biopsy was acute and chronic inflammation.

On the fourth hospital day the patient vomited several times. The abdomen was soft. No further vomiting occurred, however. Her chart remained flat, and she was discharged on the tenth hospital day.

*Third Admission* (seven months later) For several months after discharge the patient had weak spells almost every day but gained a small amount of weight. She had no vaginal bleeding and no further menses. One week before admission she noted the onset of rapidly increasing weakness followed three days later by a severe mid-abdominal pain located for the most part about the umbilicus and radiating through to the back. At the same time, nausea, vomiting and constipation developed. Her abdomen then became distended. On the afternoon of the day of admission an enema was given, with expulsion of a large amount of black fecal material. Following this her pain was greatly relieved, but recurred and was relieved by 1 gr of codeine.

Physical examination showed a well-developed and nourished woman in no acute distress. The skin of the lower mid-abdomen showed increased pigmentation and induration over a 15-cm area. Examination of the chest was negative. The blood pressure was 118 systolic, 80 diastolic. The abdomen was soft, with active peristalsis. There was acute right lower-quadrant tenderness, but no spasm. There was also rebound tenderness referred to the midline.

The temperature was 98.6°F, the pulse 80, and the respirations 17.

The urine examination was negative. The blood showed a red-cell count of 4,410,000 with 80 per cent hemoglobin, and a white-cell count of 10,900 with 87 per cent polymorphonuclears. The smear showed several band forms of polymorphonuclears, a young polymorphonuclear and an atypical mononuclear. Some of the red cells appeared somewhat larger than normal. The serum protein was 5.5 gm per 100 cc. Two stool examinations

source for such cells, except within malignant tumors, is in tissue that has been heavily radiated. I consider that finding very characteristic of post-radiation effect, and I think there is no doubt that that was the cause of the localized lesion. Certainly the picture was quite unlike that of regional ileitis, the only other condition we must seriously consider.

DR. HAMPTON: In retrospect we believe that the loop of diseased small bowel was adherent to the fundus and hence lay in the same place throughout the treatment so that by crossfire treatment the maximum dose was delivered to it.

DR. MALLORY: Under ordinary circumstances is it fair to assume that during such a series of treatments several loops would be in your field from time to time rather than one?

DR. HAMPTON: Yes.

DR. COPE: What was the lesion for which she was given the radiation?

DR. MALLORY: Carcinoma. There was never any doubt about that. So far as can be made out at the present time it has been cured.

A PHYSICIAN: Do you think the episode of vomiting represented an acute reaction in the loop of bowel?

DR. MALLORY: I do not know, it may have been that or x-ray sickness.

DR. HAMPTON: She took radiation well and worked throughout the course of treatment, there was no roentgen sickness.

A PHYSICIAN: It says she vomited all day. Presumably after the radium needles were inserted?

DR. HAMPTON: Well, perhaps so.

ease in or around the small bowel. We have fair or definite evidence that the small bowel is partially obstructed and that it was an intermittent obstruction.

**DR COPE** It looks as if we were dealing with a true tumor, and the apparent tumor is obstructed bowel. It is very difficult to say on the evidence what the type of cancer may have been, if indeed malignancy was present. The record hedges on this point, saying that the diagnosis of cancer was made at another hospital. It is perfectly possible that the bleeding may have been due to ovarian dysfunction with abnormal endometrium and not to cancer of the cervix or endometrium. An ovarian dysfunction, however, would not explain the intestinal obstruction unless it were one of those things that we hear about—radiation reaction in the presence of an old pelvic inflammation, with secondary obstruction. That does not account for the intestinal hemorrhage. The hemorrhage suggests either that a cancer is present or that it comes from an ulcer in a Meckel's diverticulum. In the absence of definite evidence, the most likely diagnosis is cancer in or around the uterus, with secondary involvement of the small bowel, obstruction and hemorrhage. Adenocarcinoma is the one thing in my experience that would fit the picture and that is my first diagnosis. My second diagnosis is Meckel's diverticulum. I believe it is possible that the original hemorrhages were on the basis of an ovarian dysfunction due to chronic pelvic inflammation, that the diagnosis of cancer was an error and that the heavy irradiation led to intestinal obstruction.

**DR TRACY B MALLORY** It is obviously a difficult diagnostic problem. Has anyone else any suggestions to offer?

**DR HORATIO ROGERS** I should think that x-ray necrosis of the intestine would have to be considered more seriously.

**DR COPE** Did you ever see hemorrhage following it?

**DR HAMPTON** And does not the hemorrhage usually occur at the time of maximum x-ray reaction?

**DR ROGERS** Dr Frank Pemberton has had some cases at the Free Hospital in which the hemorrhage came on quite late, several months after treatment.

**DR HAMPTON** I treated this woman and I gave her most of the treatment in front, crossfiring the midline. She took it very easily without nausea, and I could give her 300 r daily. She was given about 3500 r in front and the other 1000 r behind, with no very obvious reaction. We have given that same dose routinely without any such thing

as this occurring and without risk of radiation necrosis.

## CLINICAL DIAGNOSIS

Intestinal obstruction

**DR COPE'S DIAGNOSIS**

Adenocarcinoma of uterus and small intestine

## ANATOMICAL DIAGNOSIS

Post-radiation enteritis

## PATHOLOGICAL DISCUSSION

**DR MALLORY** I shall read you part of Dr Langdon Parsons's operative notes since he is not here to tell us about the findings.

On entering the peritoneal cavity, there was an escape of a quantity of thin, peritoneal fluid—obviously in response to an inflammatory condition within the abdomen. This was soon identified as being present in the distal portion of the ileum about 45 cm. from the ileocecal valve and represented a large, pie shaped area involving the root of the mesentery which was acutely edematous and thickened, about 2.5 cm. in depth. The bowel itself was involved for a distance of about 45 cm. and was loosely adherent to the top of the fundus, this could be easily stripped off with the examining finger without denuding the bowel. It had obviously not been involved in the radiation from below. While the uterus was fixed, there seemed to be no evidence of pre-existing carcinoma of the cervix and the fixation was probably due to fibrosis. The bowel in the involved area showed spots suggestive of gangrene. The entire area was devascularized, the walls were markedly thickened and contracted. The lumen was from 2 to 3 cm. in diameter. There was no marked evidence of dilatation above the point of obstruction. The entire appearance was that of an area exposed to heavy radiation. There was no suggestion of perforation of the bowel. This large loop was freed with great difficulty, the difficulty came in that the bowel was so stiff and edematous that it did not appear in the wound as normal small bowel would, even after freeing it from the uterus, but tended to bend, much as a lead pipe would. The balance of the mesentery appeared normal.

It was very obvious when the specimen reached the laboratory that the bowel wall was of unusual stiffness, and I can well believe that the operator faced a great many difficulties in manipulating it. On opening it we found hemorrhagic necrosis of the mucosa, with extension down through all layers of the bowel wall. Microscopically the most striking feature, perhaps, was the presence in many parts of the specimen, but particularly I should say in the mesentery, of fibroblasts of most unusual character—four or five times the normal size with giant nuclei and giant nucleoli and very frequently five or six nuclei in a single fibroblast, the type of cell one ordinarily considers evidence of a high grade of malignancy. The one common

it is no easy matter to persuade a patient to undergo a second operation even if it be a minor one and for his own good

If a biopsy is done, let it be performed thoughtfully, skillfully and circumspectly, with full recognition of the impossibility of any accurate diagnosis from inadequate or poorly prepared material. Lack of attention to these details may — and often does — lead to disappointment, false statistical data and even danger

### THE TUBERCULOSIS PHENOMENON

In this issue of the *Journal* is a discussion of the current programs for tuberculosis control. Many who have cultivated the habit of passing by these perennial presentations would do well to pause and read one now and then.

In the early days of the "war on tuberculosis" a great emotional stimulus was needed. Zealots were good promoters then, for they fostered the combative spirit and thus produced the action and reaction necessary to publicize and popularize the cause. At first they were mere voices, clamorous in the wilderness of a still medieval point of view toward sickness and its prevention. Gradually they began to achieve, they attracted more attention, more sympathy, more support, more acceptance of their efforts as one of the great moral movements of the day. About them there appeared the little parasitic enterprises and fads that always attach themselves to a successful venture, just as barnacles attach themselves to a mighty rock. The movement became stabilized and at length an accepted part of what is now recognized as a public-health responsibility.

No longer should we think of the "cause" or a "war." Such an emotional background is neither needed nor wanted by those who might equally resent being referred to as an "army" of workers. It is an established group of specialists, already divided into their own subspecialties, paid largely from public funds and rendering their services

largely in public institutions. They no longer need the zealots of the past. They go about their work in a deliberate, business-like manner. It makes little difference to them what kind of seals you buy at Christmas and whether you open your bedroom windows at night.

With a mortality reduction of approximately 70 per cent in the past forty years, what used to be called the tuberculosis problem not only seems well under control, but is itself already creating new problems. The momentum of eradication is greater than statisticians dared to predict a few years ago. It can easily be maintained if living standards can be maintained and early cases recognized. Within a few years the need for new beds for tuberculosis will disappear. Within a few generations the herd immunity of those who have encountered and resisted the disease will disappear. It is no longer a problem in the ordinary sense — it is a phenomenon.

### OBITUARY

RICHARD CLARKE CABOT

1868-1939

In every generation there are restless souls, who cannot be made to fit the common mold. A few of these are valuable in keeping their communities and professions in a ferment by their constant challenge to the existing order of man's thought and action. But when, in addition to possessing these attributes, a rare individual is endowed with the divine fire and makes important contributions to the pioneering progress of humanity, then indeed we recognize a great leader. In the thick of the fray such recognition comes slowly but as the smoke of the battle clears the acclaim is universal.

Richard Clarke Cabot was born in Brookline, Massachusetts, May 21, 1868, and came within two weeks of living seventy-one years. He was the fifth son of James Elliot and Elizabeth (Dwight) Cabot. After preparing for college at Noble and Greenough School, he entered Harvard University from which he received his A.B. degree, *summa cum laude*, in 1889 and his M.D. in 1892. Three other degrees he received later in life in recognition of his attainments, an LL.D. (Rochester, New York, 1930), an L.H.D. (Syracuse, 1934) and a D.D. (Colby, 1938).

In 1894 he married Ella Lyman in Waltham

## THE DEFINITIVE BIOPSY

A RECENT number of the *Cancer Bulletin*,<sup>1</sup> has commented on Ewing's<sup>2</sup> ideas concerning the use and abuse of the diagnostic biopsy. He comments at some length on the "regional indications" and states, in regard to tumors of the breast "When a woman presents a lump or induration in the breast, one assumes a serious responsibility if he delays in making a positive diagnosis. The most direct method is to remove the mass and determine its nature at once."

It is generally agreed that in the presence of a tumor a biopsy is indicated if only as "a confession of the inaccuracy of clinical judgment," but it must be admitted that there are certain dangers associated with the surgical removal of such specimens. These dangers have been fully pointed out by Ewing, and need not be enlarged on here. In

general, however, it may be stated that a positive and reasonably accurate diagnosis of any tumor must, of necessity, form the basis of effective and intelligent treatment and that a biopsy affords the simplest and surest method of attaining this end.

To the points which Ewing has made, we should add two more, applicable in particular to the less frequently employed but nonetheless important biopsies of bone tumors and lymph nodes.

For the proper diagnosis of the removed tissue, it is essential that the material be adequate in amount, satisfactorily fixed and properly stained. Nowhere is this more true than in the field of lymph-node diseases and bone tumors, yet again and again the biopsied tissue, often inadequate in amount, is allowed to dry and shrivel before fixation or is summarily dropped into an inadequate fixative in pieces too thick to allow of proper preservation. The resulting sections, often poorly cut and stained, cannot be properly diagnosed, and the pathologist is frequently forced to state "Probably malignant tumor, exact nature uncertain." Surgeons expecting to do such biopsies can easily obtain directions from competent pathologists for the proper preservation of tissue, and he who expects to send a case to some large medical center for consultation or for treatment if the mass should prove to be malignant would often be far better served if biopsy were deferred until the patient is seen at such a medical center. Neither the patient nor the referring doctor nor the consultant loses by such a procedure.

In the field of lymph nodes, one further error is not infrequently committed. There is a tendency to pass by the large nodes and remove one which is small and perhaps more readily accessible. Not infrequently such a node is found to be merely the site of an inflammatory or hyperplastic process in no way indicative of the major underlying disease. The pathologist may be compelled to report "No evidence of tumor formation", nor can he justifiably modify this statement on the basis of the clinical findings. The histological evidence before him is clearly indefinite, through no fault of his own. He can, at best, suggest another biopsy, but

workers still pioneering in social service within and without the walls of the old hospital. All parts of the world have followed the example set by this group, just as they have studied Cabot's *Physical Diagnosis* and *Clinicopathological Conferences* and recognized his epoch-making medical contribution of 1914.

During the second decade of the century Dr Cabot continued his intensive work in medicine and social service, adapting it from 1917 to 1919 to suit the changed conditions of the days of the World War, when he served as chief (major to lieutenant colonel, Medical Corps) of the medical staff of Base Hospital No. 6 (Massachusetts General Hospital Unit) in the A. E. F. in France, and under the Red Cross established dispensaries for refugees and lectured in French on social work at the Collège de France. In 1912 he was appointed as one of the two chiefs of the medical staff at the Massachusetts General Hospital, which position he held till his retirement in 1921, and in 1919 he was appointed professor of clinical medicine and professor of social ethics at Harvard, not a whole settee as in ancient days but twice as many chairs as has been possible for the average mortal to occupy in our own generation.

It was in 1914, however, just at the beginning of the World War, that Dr Cabot made his most important medical contribution in a short but vital paper published in the *Journal of the American Medical Association*, a landmark in medical history, which places him as the greatest contributor to cardiology in our generation. The war undoubtedly obscured this advance,—as it did that other very important American contribution to cardiology by Dr James Herrick, of Chicago, on coronary thrombosis in 1912,—but now, after twenty-five years we can appreciate its full significance, and Dr Cabot's name becomes associated with that of Sir James Mackenzie as a prime leader in the field of heart disease in the past half century. Yet he made this significant contribution merely in passing, as it were. Although heart disease was one of his pet hobbies in medicine,—witness his volume *Facts on the Heart* (1926),—it was a lesser interest after all, and he never pretended to be a heart specialist.

To some who are not cognizant of the great advances in cardiology since the World War this contribution of Dr Cabot's in 1914 may still be news, but to those of us who have concentrated in the field it is the foundation of much if not most of our work in the last two decades. The paper was entitled "The Four Common Types of Heart Disease." For the first time, proper emphasis was laid on the etiologic diagnosis of heart disease, in contrast to the overemphasis of struc-

tural defects that had been current for over two hundred years. The revolution in point of view has been amazing. Where at one time, in fact for generations, textbooks and papers had been preponderantly involved with such subjects as mitral regurgitation, myocarditis and pericarditis, they now present as a primary interest the causes of heart disease. Not only has such a viewpoint become of major importance in routine diagnosis, prognosis and treatment, but it has also stimulated the essential studies of the etiologic factors behind heart disease with much promise in the fundamental field of preventive medicine. Sir James Mackenzie's great service to cardiology was in setting forth clearly the need of paying attention to disorders of function of the heart, Dr Cabot's contribution on etiology was even more significant.

It was during this same decade, 1910 to 1920, that Dr Cabot pioneered in still another medical field and thereby aroused the ire of many physicians and medical societies. In his militant bluntness and precipitate desire to correct the errors of the practice of medicine he wrote to the laity on the subject of *Better Doctoring for Less Money*, many years before it became fashionable to belabor the family doctor or specialist. Many persons with less of the zeal of the impetuous reformer believe that there are gentler and perhaps wiser ways to correct the errors of today than by substituting the errors of tomorrow, but undoubtedly these stormy methods have a certain value in hastening the return to a sensible equilibrium after all the shouting and the tumult have subsided.

Another extracurricular activity of Dr Cabot's took place for a few months prior to the entrance of the United States into the World War. Believing strongly in the need of our taking the side of England and France on the battlefield itself, he and his wife went West on a vigorous speaking tour to rouse the country and did not stop until war was declared. He could not sit still when something in which he had his heart needed to be done.

In completing this brief glimpse of Dr Cabot's rich life, let us view the post-war years, the last two decades. After the stirring days of the quarter century following the beginning of his professional career this latter period became relatively peaceful, actually richer and riper. To some who did not sense this change it seemed almost as if he had retired. On the other hand he went on to higher levels, leaving to us others the study and the care of the body. With the years he came to realize with increasing force the need of the study and the care of the spiritual side of man, his character and personality, truly, his soul.

and spent the next half year traveling and studying in Europe before settling down to practice and to begin his teaching and researches at 190 Marlborough Street in Boston. His married life was an extraordinarily happy one and continued fortunately for forty years. The devotion of Dr Cabot and his wife to each other was a constant joy to their friends and a source of inspiration for much of his philosophical writing.

It is not possible to divide Dr Cabot's life into clear-cut periods of activity, for one interest merged into another gradually and naturally. In fact what some consider a late interest, namely philosophy, came early in life as shown by the facts that he was a lecturer in that subject at Josiah Royce's Harvard Seminary course in logic in 1903-1904 when but thirty-five years old and that in 1905 at thirty-seven he inaugurated social service at the Massachusetts General Hospital. It is true, however, that the earlier half of his professional life was preponderantly concerned with medicine and the later half with social ethics.

Twenty-five years ago when I presented a letter of introduction from him to a medical leader abroad he expressed surprise that Dr Cabot could still be alive after such a record as he had already made. And yet he was then only forty-five years old.

The reason for Dr Cabot's early fame in medicine was his great ability and industry in pioneer work. He was indefatigable to the end of his days and always a pioneer. At the age of twenty-eight, in 1896, he published his first book *Clinical Examination of the Blood*, which went into five editions in eight years. In 1899, at thirty-one, he published *Serum Diagnosis of Disease*. His service in the Spanish-American War on the hospital ship *Bay State* as lieutenant in the Medical Corps was a great stimulant to his increasing interest in the blood and in infectious diseases. But soon he left these fields, although he could easily have continued in them as a leading authority had he so chosen. He feared a narrowing of his viewpoint. In the ten years from 1901 to 1911 he wrote three medical books of wide interest, the first of which, *Physical Diagnosis*, has been used the world over as a textbook and has appeared in twelve editions from 1901 to 1938 (the last edition with Dr F. Dennette Adams). The other two medical books published in that decade were *Case Histories in Medicine* (1906) and the first volume of *Differential Diagnosis* (1911), the latter went into four editions from 1911 to 1919 and was followed by the second volume, of which there were three editions from 1915 to 1924.

More important, however, than any of his books in that decade was his introduction of autopsy

teaching in 1910, the first of the long and continuous series of his famous *Clinicopathological Conferences* that are still carried on actively at the Massachusetts General Hospital in a modified way. Dr Cabot was an incomparable teacher, a master at this kind of exercise, always willing to commit himself to stimulate his students and his colleagues to learn through their errors as he did through his own.

During this period of intensive medical work 1901 to 1911, Dr Cabot also carried on a practice and served at the Harvard Medical School (appointed instructor in medicine in 1903 and assistant professor in 1908) as well as at the Massachusetts General Hospital (physician to the Out Patient Department in 1898 and assistant in medicine in 1899). From 1902 to 1929 he conducted very popular summer courses in internal medicine at the hospital. These were attended by physicians from all parts of the country and constituted pioneering work in the important but neglected field of postgraduate medical education in the United States.

It was still in that decade of his greatest medical activity that Dr Cabot made his second vital contribution, in another though related field. In 1905 he started medical social service at the Massachusetts General Hospital and in 1909 wrote a book *Social Service and the Art of Healing* of which there was a second edition in 1928.

In 1930, when a special Social Service Fund was raised for educational purposes in commemoration of the twenty-fifth anniversary of the beginning of hospital social service, Dr Mary Lawson wrote

I am so glad that you asked me to give my bit to continue the wonderful work that Dr Cabot started. I remember its beginning very well. I was with him at the time. Did you know that he had something of the kind in mind ever since he was a small boy of ten? I do not believe there is anyone more thoroughly acquainted than I am with the wonderful unselfishness of Dr Cabot's character. He is always doing something for others. When he started the work he had to meet so much unbelief in its usefulness, but he has that wonderful gift of seeing beyond and he knew what its future would be. It started in a little corner of a corridor in the Out Patient Department surrounded by screens, with one paid worker and volunteers. Dr Cabot consulted with and advised the helpers daily, being himself responsible for all financial aid beyond what little might be given by subscription. The work was Dr Cabot in those days.

This tradition of service Dr Cabot maintained to the end of his years, passing on in the course of time most of the responsibilities and a host of important developments in this social service field to the able leader who has taken his place, with her own mantle as well as his, Ida M. Cannon. Miss Cannon has surrounded herself with other

the uterus passes through the cervix and may even appear outside the vulva. The condition occurs chiefly in the presence of atony. First there is a dimpling or cupping of the fundus of the uterus, which may be due to the weight of a high implanted placenta, to a forcible attempt to deliver a relaxed uterus or to traction on the cord. The fundus projecting into the uterine cavity acts as a foreign body and stimulates forcible contractions of the rest of the musculature in an attempt to expel it—hence the complete inversion.

Inversion of the uterus is generally accompanied by profound shock and profuse hemorrhage. The diagnosis should be easy. The fundus can no longer be felt above the symphysis. There is a large, rounded, spongy mass protruding from the cervix, associated with profuse bleeding and signs of collapse.

Successful treatment depends primarily on improving the condition of the patient before any measures to replace the uterus are undertaken. The profuse bleeding may generally be controlled temporarily by firm packing of the vagina, intravenous fluids and transfusions should be given. Then, and not until then, it is proper to attempt a gentle manual reposition of the uterus. At times this can be successfully accomplished under ether anesthesia, often, however, it will be found that the cervix has shut down so tightly that it is impossible to push the large boggy fundus through it.

Should this be the case, immediate operation of the type suggested by Huntington\* is the method of choice. The patient is placed in Trendelenburg position, anesthetized and prepared. The abdomen is opened in the lower midline. A funnel-shaped depression at the site of the cervix is then evident from within the pelvis, with the tubes and round ligaments leading into the opening. The operator and his assistant, each armed with Allis forceps, then grasp the invaginated portion of the uterine wall about 2.5 cm below the cervix and draw it gently upward. New bites are taken just below the original ones, and thus the fundus of the uterus is gradually returned to the abdominal cavity, that part which went through the cervix last being the first to be withdrawn.

If the uterus is not replaced, the patient may recover from the shock and hemorrhage and live to face the dangers of sepsis. Rarely there may be a spontaneous return of the uterus to the abdomen, but cases have been reported in which the cervix has shut down so completely that gangrene and sloughing of the fundus have occurred.

When untreated, the condition occasionally

passes on to the chronic stage, with marked involution or atrophy of the fundus. In chronic cases in which the inversion has been present for more than a month it is usually impossible to replace the uterus without splitting the cervix by some form of vaginal operation.

This condition is of interest in Massachusetts because in 1937 there were two deaths from inverted uterus, and in 1938, one. Subsequent case reports in the *Journal* will deal with acute and chronic inversion of the uterus.

## LEGISLATIVE NOTES

The approved enabling act for medical insurance was presented to the Committee on Rules of the Massachusetts Legislature on June 8. No report had been made on it up to June 21. The proposed act reads as follows:

### AN ACT ALLOWING THE INCORPORATION OF NON-PROFIT MEDICAL SERVICE CORPORATIONS.

Be it enacted by the Senate and House of Representatives in General Court assembled, and by the authority of the same, as follows:

**Section 1.** Any corporation organized under the laws of the Commonwealth for the purpose of establishing, maintaining and operating a non-profit medical service plan whereby the cost of certain medical care and service may be paid for in whole or in part by such corporation, to such of the public as become subscribers to said plan under a contract which entitles each subscriber to specified payments for the cost of certain medical care or service, shall be governed by this chapter and shall be exempt from all provisions of the insurance laws of the Commonwealth, except as otherwise provided in this chapter. Wherever the term medical care and service is used in this chapter it shall be deemed to include surgical care and service and the term physician shall also be deemed to include surgeon. The term medical care and service as used in this section shall be construed to be medical care and service as defined by the statutes of Massachusetts and the opinions of the Massachusetts Supreme Court.

**Section 2.** Persons desiring to form such a non-profit medical service corporation shall incorporate as provided in section three of chapter one hundred and eighty. At least a majority of the directors of such corporation shall be at all times persons licensed to practice medicine in the Commonwealth. Every certificate of organization of a corporation subject to this chapter filed under said chapter one hundred and eighty shall have endorsed thereon or attached thereto the consent of the Commissioner of Insurance and of the Commissioner of Public Welfare.

**Section 3.** Any corporation subject to this chapter may enter into contracts with persons, to be known as subscribers, calling for the payment by such corporation, subject to such limitation and at such rates as shall be specified in such contracts, of the cost of medical care furnished to such subscriber, or to his or her dependents or family, by a physician or physicians licensed to practice medicine. All such contracts with subscribers shall be in writing and the terms and provisions thereof shall at all times be subject to the approval of the Commissioner of Insurance. The rates or bases at or upon which physicians are to be compensated for medical care or service rendered to or for the benefit of a subscriber shall

Huntington, J. L. Acute inversion of the uterus. *Boston M. & S. J.* 184, 376-380, 1911.

Through the years by a process of natural evolution he came to be less interested in man's body or even in man's mind than he was in his soul. Even in the hard war years I can recall in many quiet conversations with him how impatient he was with the mere healing of wounds and illnesses, and the education to be found in most schools and universities. Morons can be superbly healthy, criminals can be highly educated. It was the spiritual quality of any individual that attracted his attention, and the possibility of its cultivation that became to him a challenge. Probably to most mortals this realization comes with force enough to demand attention only in advanced age when it is too late to act, but Dr. Cabot was still strong and full of years when he set to work to tackle these problems. This richest part of his life, too recent for us, is least known and appreciated. One of the studies inaugurated during the last few years—the Cambridge-Somerville Youth Study—will take ten more years to run.

Scant witness of Dr. Cabot's growing interest in human society and in man's soul is to be found in a number of books published in the last twenty-five years of his life: *What Men Live By* (1914), *Adventures on the Borderland of Ethics* (1926), *The Goal of Social Work* (1927), *The Meaning of Right and Wrong* (1933, 1936), *The Art of Ministering to the Sick* (with Reverend R. L. Dicks, 1936), *Christianity and Sex* (1937), and *Honesty* (1938). When he died he was at work, with a literary friend, on what he believed to be his most important philosophical treatise, a summing up of values in life.

I cannot forbear mention of Dr. Cabot's final illness, which lasted nearly a year after more than twenty years of bother with both peptic ulcers and angina pectoris (despite which he played tennis until nearly seventy). Uncomplaining and brave, he followed the course of his own heart failure with great interest, challenging our diagnoses if he thought we were off the track and helpfully too, and hastening to concede the value of various medicines as we gave them, completely wiping out any reputation he may have had earlier in life as a therapeutic nihilist. He always demanded to know the truth of what we thought about his condition and did not flinch from pain or from the realization of his grave prognosis. He persuaded us to allow him for his mind's sake to work on his books and to teach, even when he was an invalid. What he did in this way seemed to help him physically also, as he predicted. For months his classes came to his bedroom twice a week and cherished this privilege as they will the memory of it.

His death ends a life of great service to man.

Had he accomplished what he did in any one of his three chosen fields—medicine, social service, ethics—it would have been more than enough.

Through his last will and testament his spirit will continue to be active for many years to come. With rare wisdom he has bequeathed in his wife's name a fund to be used by trustees whom he selected to foster the work of any individuals not otherwise adequately supported who give promise of making important contributions to humanity in any field of activity: art, music, literature, philosophy, theology, education or science. Causes and institutions merely as such he did not wish to help, but as they are related to individuals of promise they may be incidentally benefited.

To others I must leave an account of his interests and talents in music, dramatics, literature and religion—his sense of perfect pitch, his Christmas carol choruses on Beacon Hill, at the Massachusetts General Hospital and in France, his skill with the violin, his readings of poetry and prose to groups of friends, his acting in theatricals, his sermons and his Sunday School lessons. To one person above others, Alice O'Gorman, Dr. Cabot's secretary, I add a special word of tribute, without her constant and skillful aid, her quiet encouragement and her understanding care he could not have accomplished what he did.

To me, as to many others, Richard Cabot was always a stimulating counsellor, vigorous critic and warm-hearted friend. In his example he has left a great heritage.

#### INVERSION OF THE UTERUS

Inversion of the uterus is a rare complication of labor. The incidence varies in accordance with the author from 1 in 20,000 to 1 in 190,000 deliveries. It generally accompanies or follows the birth of the placenta and is more frequent in primiparas. The mortality as quoted in the literature is high, but with immediate recognition and proper treatment it should be low. It may be spontaneous or induced, it may be partial or complete. In the complete cases the fundus of

\*A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

**GIBSON**—**DAVID H GIBSON, M.D.**, of 115 Mt. Auburn Street, Cambridge, died June 8. He was in his fifty fifth year.

After attending Cambridge Latin School he received his degree from Tufts College Medical School in 1921. Dr. Gibson was a member of the Massachusetts Medical Society and the American Medical Association.

His brother survives him.

**REYNOLDS**—**GEORGE P. REYNOLDS, M.D.**, of Brookline, died June 6. He was in his forty second year. He graduated from Milton Academy in 1915 and spent the following year at Phillips Andover Academy. He received his degree from Harvard College in 1920 and from the Harvard Medical School in 1924, and interned at the Massachusetts General Hospital. After serving as assistant medical resident at Johns Hopkins Hospital he became assistant in medicine on the staff of the Massachusetts General Hospital and was appointed junior visiting physician on the staff of the Boston City Hospital in 1928. Dr. Reynolds was assistant in medicine at the Harvard Medical School from 1928 to 1935 when he was appointed instructor in medicine, which position he held at the time of his death. He was particularly interested in medical social service work and in the application of practical psychological principles to the care of patients, and had contributed several articles on both topics.

In September, 1934, he was made physician to Milton Academy. Dr. Reynolds joined the Massachusetts Medical Society in 1927, serving as secretary to the Suffolk District Medical Society from 1933 to 1935. He was a member of the Council of the Massachusetts Medical Society from 1933 to 1937, being on the Committee of Arrangements from 1929 to 1934 and chairman of that committee in 1933. Dr. Reynolds was a fellow of the American Medical Association.

His widow, three daughters, his mother and a brother survive him.

## NEW HAMPSHIRE MEDICAL SOCIETY

**HARRIMAN**—**ALPHA H. HARRIMAN, M.D.**, of Laconia, died on May 30, after a long illness.

He was born in Albany, New Hampshire, on October 14, 1857, the son of Nathaniel and Rhoda A. Harriman. He was graduated from Bowdoin Medical College in 1883 and moved shortly to Sandwich, where he remained for three years before going to Laconia in 1887.

Dr. Harriman held memberships in the New Hampshire and Winnepesaukee medical societies.

Survivors are his widow, Mrs. Alice S. Harriman, a son, N. Joy Harriman, a daughter, Mrs. Murray W. Wright of Nashua, and four grandchildren.

**MACLEAY**—**ALFRED A. MACLEAY, M.D.**, aged sixty nine, died Thursday, June 1, at the Notre Dame Hospital in Manchester after a long illness. Dr. Macleay, a native of Canada, came to Manchester from London, England, in 1899 and practiced as an eye, ear, nose and throat specialist until he retired because of ill health in 1932.

He was born in Castlebar, Quebec, October 8, 1869, the son of Alexander Monroe and Rosanna (Riddle) Macleay. He prepared for college at St. Francis School, Richmond, Quebec, and attended McGill University and Medical School, receiving the degrees of bachelor of arts, doctor of medicine and master of surgery.

Dr. Macleay was a life member of the British Ophthalmic Hospital in London, an honor granted him in recognition of his services there. He also was a member

of the Canadian College of Medicine, the American Medical Association, the American Surgical Association, the New Hampshire Surgeons Club and the state, county and local medical associations.

Besides his widow, the deceased is survived by a daughter, Mrs. Margaret Macleay Leavitt, a brother, Roderick Macleay, of High River, Alberta, and a sister, Mrs. John A. Wadleigh, of Danville, Quebec.

**TIBBETTS**—**GUY D. TIBBETTS, M.D.**, aged fifty-one, died at Antrim, New Hampshire, on June 2.

He was born in Gloucester, Massachusetts, and was graduated from Tufts College Medical School in 1911. Dr. Tibbetts was one of 1000 American doctors loaned the British Government during the World War and for his services was awarded the Distinguished Service Cross.

He was a member of the Reserve Officers Corps, with the title of major, the Honorary Medical Society of Tufts College, the American Medical Association, the Hillsboro County Medical Association and the New Hampshire Medical Society.

## MISCELLANY

### HONORARY DEGREES AT BOSTON UNIVERSITY

Two doctors of medicine whose careers have been remarkable not only for services rendered but in length of time were presented honorary degrees in recognition of their achievements at the Boston University sixty sixth annual commencement exercises held on June 12.

Drs. J. Emmons Briggs, of Boston, and William Otis Faxon, of Stoughton, were awarded the honorary degrees of Doctor of Science. Both are graduates of Boston University School of Medicine, and Dr. Faxon is the oldest living graduate of the medical school in active practice.

Dean Jesse B. Davis, of the School of Education, presented Dr. Briggs for the degree, and the latter was cited by Dr. Daniel L. Marsh as "son of Boston University, whose superb abilities have been consecrated to the assuaging of human suffering and the advancement of medical science. Dr. Marsh's citation for Dr. Faxon, who was presented by Dean Alexander S. Begg, of the School of Medicine, was "oldest living graduate of Boston University School of Medicine in active practice, for sixty three years a glorious illustration of the finest connotation of the doctor in the home."

### PNEUMONIA AND ALLERGY EXHIBITS AT THE NEW YORK WORLD'S FAIR

In the Medicine and Public Health Building, New York World's Fair, Lederle Laboratories are sponsoring the scientific exhibits on pneumonia and on allergy, each exhibit being controlled by a committee of eminent specialists on these diseases.

The pneumonia exhibit, surfaced entirely of white laminated beetle, occupies a booth 20 by 30 feet in a commanding position. It presents, pictorially, the best composite opinion of the medical profession on how a pneumonia case should be treated. The narrative is unfolded by means of a sequence of dioramas, pictures and charts. The story begins with an animation of a man walking in the rain, and takes him through typing and serum therapy and all the various progressive stages of a typical case of pneumonia to a final picture at the serum farm where his little daughter is pictured, saying "Thanks,

whenever the compensation of such physician is to be paid by such corporation, be approved by———

**Section 4** Every such corporation shall annually, on or before the first day of March, file in the office of the Commissioner of Insurance a statement, verified by at least two of the principal officers of said corporation, showing its condition as of the thirty-first day of December next preceding. Said statement shall be in such form and shall contain such other matters as the Commissioner of Insurance shall prescribe. A corporation neglecting to make and file its annual statement in the form and within the time specified shall forfeit one hundred dollars for each day during which such neglect continues, and, upon notice by the commissioner to that effect, its authority to do new business shall cease while such default continues.

**Section 5** The Commissioner of Insurance, any deputy or examiner, or any other person whom said commissioner shall designate, at least once in three years and whenever he deems it to be prudent, shall visit any such corporation and examine into its affairs, shall have free access to all the books, papers and documents of the corporation that relate to its business, and may summon as witnesses and examine under oath its officers, agents or employees, or other persons in relation to its affairs, transactions and condition. The commissioner shall require every such corporation to keep its books, records, accounts and vouchers in such manner that he or his authorized representatives may readily verify its annual statements and ascertain whether the corporation has complied with the law.

**Section 6** All acquisition costs in connection with the solicitation of subscribers to such medical service plans shall at all times be subject to the approval of the Commissioner of Insurance.

**Section 7** The funds of any corporation subject to this chapter shall be invested only in securities permitted by the laws of the Commonwealth for the investment of the capital of life insurance companies. The directors or other officers of such a corporation making or authorizing an investment or loan not included in the securities permitted for investment shall be personally liable to the corporation for any loss caused thereby.

**Section 8** If the Commissioner of Insurance is satisfied that any corporation subject to this chapter has failed to comply with the provisions of its charter, or is being operated for profit, or is fraudulently conducted, or if said commissioner is satisfied that its condition is such as to render its further transaction of business hazardous to the public or to its subscribers, or if, in the opinion of such commissioner, (a) the officers and agents of such corporation have refused to submit to an examination under section five, or (b) such corporation has exceeded its powers or violated any provision of law, or (c) it has attempted to compromise with its creditors (other than physicians) on the ground that it is financially unable to pay its claims in full or is attempting to do so, or (d) it is insolvent, then, in any such case, he may apply to the Supreme Judicial Court for an injunction restraining it from further proceeding with its business in whole or in part. The court may forthwith issue a temporary injunction restraining the corporation from further transacting any business, and it may, after a full hearing, make the injunction permanent, and appoint one or more receivers to take possession of the books, papers, moneys and other assets of the corporation, and settle its affairs, and distribute its funds to those entitled thereto, subject to such rules and orders as the court may prescribe.

**Section 9** Every corporation subject to this chapter is hereby declared to be a charitable and benevolent corporation, and its property shall be exempt from state, county, district and municipal taxes.

**Section 10** No corporation subject to this chapter shall pay any salary, compensation or emolument to any officer, trustee or director thereof, as such, nor shall it pay any salary, compensation or emolument amounting in any year to more than \$5,000 to any person, unless such payment be first authorized by a vote of its board of directors, provided, however, that such limitation shall not be applicable to the compensation paid to a physician for medical care and service rendered to subscribers. No corporation subject to this chapter shall make any agreement with any of its officers, trustees or employees where by it agrees that for any services rendered or to be rendered to the corporation he shall receive any salary, compensation or emolument that will extend beyond a period of three years from the date of such agreement.

CHARLES C LUND, M.D., *Chairman,*  
Committee on State and  
National Legislation.

## DEATHS

**ALLISON**—CARL E ALLISON, M.D., of Wakefield, died June 9. He was in his fifty second year.

Dr Allison received his degree from the Tufts College Medical School in 1914. He was a member of the Massachusetts Medical Society and the American Medical Association, and had practiced for twenty years in Wakefield.

His widow and a son survive him.

**BERG**—TECLA A J BERG, M.D., of 109 Broad Street, Lynn, died June 8. She was in her seventy first year.

Born in Ostersund, Sweden, she came to the United States when she was twenty five years old and received her degree from the Tufts College Medical School in 1898. A member of the Massachusetts Medical Society and the American Medical Association, she was one of Lynn's oldest women physicians, having practiced there for forty-one years.

A brother, Dr Ernest J Berg, professor of electrical engineering at Union College, Schenectady, New York, survives her.

**DONOGHUE**—JOHN J DONOGHUE, M.D., of Worcester, died March 21. He was in his sixty fifth year.

Dr Donoghue received his degree from the University of Michigan Department of Medicine and Surgery, in 1904. He was a former member of the Massachusetts Medical Society.

**GAYLORD**—JAMES F GAYLORD, M.D., of Springfield, died June 8. He was in his fifty first year.

Born in South Hadley, he received his early education there. He attended Dartmouth College and received his degree from the Dartmouth Medical School in 1914. He was a fellow of the Massachusetts Medical Society and the American Medical Association and was also a member of the Springfield Medical Association of which he was a former president, and the Alpha Kappa Kappa Medical Society.

His widow, two sons, a daughter, a brother and three sisters survive him.

associates, circulatory collapse was induced in the volunteer subject by the oral administration of 2 to 3 gr of sodium nitrite. There was no or slight effect on the subject in the horizontal position but if he was suddenly tilted up to an angle of 75 or 90 degrees, syncope was an immediate result. If slowly tilted to 70 degrees, a state was obtained in which the systolic blood pressure stayed roughly at 60 or 70, consciousness was maintained but the mental horizon was definitely narrowed, the heart rate rose, and there was an ashen pallor and beaded perspiration. This state progressed gradually, as the blood pressure dropped, and the picture simulated exactly that commonly seen in certain infectious diseases and described in circulatory collapse. If sufficient time had elapsed, the experimental subject would have gone into a state of shock. Therefore, one may postulate a common etiology for syncope, going on to collapse and then shock.

In all three states there is a disproportion between the circulating blood volume and the total vascular volume, there is a decrease in the return flow of blood to the heart, and also an acute or subacute cerebral anoxia. In ordinary syncope there is a temporary pooling of blood in the peripheral vascular system, in circulatory collapse the return is less rapid than in syncope, in shock, even if the balance is restored by one means or another, the patient will not return to normal for some time, perhaps never, or in other words, some permanent damage has occurred. Shock can be defined as a condition with a tendency to a irreversible process, whereas syncope and collapse are usually reversible.

In the literature, the terms 'collapse and shock' are used interchangeably by many. There have been no very satisfying classifications, and the distinction between medical and surgical shock in particular is unwarranted.

From the point of view of treatment it is important to know whether collapse and shock are due (1) to the loss of some normal body constituent or (2) to the action of some substance produced in the body of some extrinsic agent. Treatment is dramatic, prognosis excellent in the first or the deficiency type, treatment is much more difficult and prognosis much poorer in the second or toxic type.

Dr Weiss recapitulated by showing several charts, the results of his experiments. The decrease in return of blood flow may reach values of 30 to 40 per cent below normal before acute circulatory collapse supervenes, and even more if produced gradually. Vein stretchability is a definite factor in the pooling of peripheral blood. Epinephrine has no effect on collapse induced by nitrite, and pitressin accentuates the collapse.

A few special features of circulatory collapse and shock as regards treatment were presented. Dr Weiss believes that too much emphasis has been placed on watching the course of arterial blood pressure in cases where collapse is a possibility. The arterial pressure is not a measure of blood flow. Thus, due to arteriolar constriction, the blood pressure may be normal but the flow very poor. On the other hand, when there is arteriolar dilatation, the blood pressure drops and the pulse rate falls, and yet no fainting occurs because the blood flow is good. Adrenalin thus may have little effect on blood pressure as compared with its marked action on the rate of blood flow. The clinical picture is one of anxiety, pallor and perspiration, and is typical of circulatory collapse. The diagnosis of collapse is warranted, in spite of the fact that the arterial pressure is normal. Certain persons may maintain a low pulse in the presence of collapse because their controlling vagal mechanism is peculiarly sensitive. Anesthesia collapse is probably due in part to an increased tendency to collapse

depending on the nature of the specific clinical condition, on fear, debility, and so forth. Superimposed on this there is the intrinsic effect of the anesthetic and of the surgical trauma. Cold is a factor in collapse, as in diabetic coma. The suddenness with which collapse comes on is explained on a basis of high activity of the reserve peripheral mechanisms, these reserves maintain normal balance for a definite length of time.

Recent efforts have been directed toward determining the degree of predisposition to collapse and shock in normal persons. One has not been able to foretell such a tendency, since powerful longshoremen fall victims as readily as do asthenic individuals. Certain tests with histamine have been used preoperatively abroad, but their value is still doubtful. There are certain general predisposing factors: (1) the patient's mental state, (2) a low blood sugar, or starvation, (3) fear, which is very significant in explaining certain serum reactions, (4) the heavy-set, plethoric individual, (5) advancing age, (6) sex.

Dr Weiss presented a summary chart of measures for prevention and treatment. Specifically, deficiencies are to be supplied, such as water, salts, blood, oxygen, protein, glucose, 'cortin,' heat, and certain vitamins, such as vitamin B<sub>1</sub> in beri-beri, abnormal factors are to be eliminated or remedied, such as sleeplessness, fear, pain, toxins, and chemical poisons. Symptomatically, the following measures are instituted to improve the circulation in general: shock position, heat or cold, blood transfusion, the administration of glucose, sucrose or gum acacia, sodium bicarbonate for the acidosis which usually develops. The value of drugs, such as strychnine, caffeine, coramine, cardiazol, ephedrine, and amphetamine (Benzedrine), epinephrine, synephrine, paredrinol and pitressin, was discussed.

The discussion of Dr Weiss's paper was opened by Dr Herrman L. Blumgart. The distinction between congestive heart failure and peripheral circulatory collapse is that in the former the veins are engorged, in the latter they are empty. He and Dr Altschule had found that it took more than 20 cc of physiological saline or 5 per cent glucose solution per minute intravenously to increase the work of the heart up to 100 per cent. In treating collapse, then, one should give 40 to 50 cc. of fluid per minute, but with careful attention to the patient's response. They also found that amphetamine raised the blood pressure without increasing cardiac output, as does epinephrine. Recent postmortem research has demonstrated conclusively that collapse causes changes in certain organs as a result of thrombosis of the vessels.

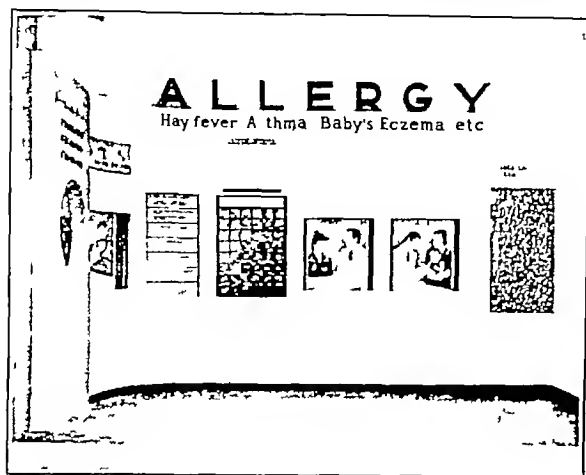

Dr Charles G. Mixer discussed the subject of surgical shock. Primary shock is rare at present, being largely due to industrial or automobile accidents. Secondary shock is relatively common and is distinguished by not coming on until about forty-eight hours after the original injury. Whereas primary shock is best treated by immediate operation, secondary shock does much better after long delay,—of days, if necessary,—during which time the patient is reassured and his physiological balance restored as much as possible. The surgeon then must choose a proper form of anesthesia, induce good sedation, and see to it that the necessary amount of heat is supplied and that the head is kept in a lowered position. The incision should be wide so as to forestall pulling and stretching of structures.

Dr Jacob Fine brought up the question of primary 'peritoneal' shock, and emphasized the importance of psychogenic factors in treatment and prevention.

Dr Weiss answered several questions put to him by physicians in the audience. He had had no experience

old horse, you saved my daddy's life! A postscript" deals with sulfapyridine.

The exhibit on allergy tells, in changing dramatic sequences, three two-minute dramas of allergy: Tommy Todd's Autumn Colds; "Mrs. Tucker's Wheezes" and

'Baby Bing's Eczema.' By means of an animated question box and dioramas showing typical scenes in the doctor's office, a search for the offending allergic excitant in each of the three stories is conducted through information obtained by questions, scratch tests and an examination of the patient's family tree. An interesting part of the allergy exhibit is an illuminated transparency chart showing in full color, forty-eight of the most common allergic excitants. A separate series of little pictures invites the visitor to examine commonplace scenes for causes of allergy and then, by pressing buttons, to illuminate the concealed answers.

Physicians visiting the New York World's Fair are entitled to exclusive privileges to the Professional Club in the same building. Admission is obtained by simple identification as a doctor, without charge.

## CORRESPONDENCE

### ANNUAL DISCOURSE

*To the Editor* Before drawing conclusions from my paper in Worcester regarding medical practice in Massachusetts, it is only fair to all concerned that those who did not hear me speak should read *all* that I said and not depend on abstracts which do not indicate the friendly, co-operative spirit in which the subject was presented. I understand that very shortly you are to print the entire paper, and I trust it will receive as much attention as the few excerpts which appeared in the press.

ELLIOTT P. JOSLIN, M.D.

81 Bay State Road,  
Boston, Massachusetts

## REPORTS OF MEETINGS

### GREATER BOSTON MEDICAL SOCIETY

A meeting of the Greater Boston Medical Society was held in the Beth Israel Hospital Auditorium on Tuesday, February 7. Dr. Louis M. Freedman presided and introduced the speaker of the evening, Dr. Soma Weiss, who spoke on 'Etiological Factors and Therapeutic Measures in Circulatory Collapse and Shock.'

Dr. Weiss stated that in the general field of diseases of the cardiovascular system, the three main disturbances are heart disease and congestive failure, arterial hypertension, and circulatory collapse. Of the three, the last is of the greatest importance and has been studied at the Thorndike Memorial Laboratory during the past eight years.

Circulatory collapse, or acute disintegration of the peripheral circulatory system, is by no means the same thing as congestive heart failure, and is commoner. The distinction between the two is important for therapeutic reasons, for example, in pulmonary edema with cardiac asthma venesection may be a life saving measure, whereas in pulmonary edema with circulatory collapse, venesection may lead to death. However, the distinction must not suggest a too arbitrary segregation of the two conditions, for they may co-exist. Such is sometimes the case in diphtheria, for example, or in beriberi, with an affection of both the heart and the peripheral vascular system. Certain drugs, such as the barbiturates, may also produce this picture. Even congestive heart failure itself may be complicated by peripheral circulatory collapse.

Peripheral circulatory collapse has been variously described as syncope, collapse and shock. The study of shock in animals and man is an old one. Dr. Weiss and his co-workers became interested in the hemodynamics of shock as a result of previous work in carotid sinus syncope.

Dr. Weiss first discussed vasomotor reactions in normal subjects. The peripheral vascular system (of which the arterioles and venules are the most important elements) has as great a significance as the heart. Thus the capacity of an athlete depends not only on his having a good heart, but also on the state of response or "condition" of his peripheral vascular system, and the degree of economy with which it functions. In heart disease, the peripheral vascular system has great compensatory powers. Arteries, arterioles, capillaries, venules and veins all have their capacity for independent action, when tested with epinephrine, choline, histamine, nitrites, and so forth, and there is a wide variation in the response to these in each individual. This has an important bearing on the tendency to collapse or shock. Slides were shown, describing graphically the results of experiments, such as the effect of a loud noise or a deep breath. Epinephrine causes a rise in systolic pressure, a drop in diastolic pressure, and a rise in pulse rate, the plethysmograph recorded a rise in blood flow through the forearm but a drop in that of the hand and foot. This latter is explained on the basis that the forearm consists mostly of muscle and has relatively little skin.

Dr. Weiss next considered the disturbances of the vasomotor system. A healthy, normal individual watching a parade on a warm day might suddenly become weak and turn pale, with an ashen color and beads of perspiration, and finally, in from 10 to 20 seconds, might collapse and become unconscious. His arterial pulse will be weak or absent, the heart rate first rapid and then slow, the blood pressure low or indeterminate. This is 'vaso-vagal syncope,' a benign condition but nevertheless alarming.

In another case, a patient with severe, acute pancreatitis also might suddenly turn pale and ashen gray, with beads of perspiration on his forehead, a rise in heart rate, a drop in blood pressure, and a drop in pulse rate. This, lasting for 5 to 20 minutes is circulatory collapse—a serious syndrome. If this state lasts for several hours or even days, it is called 'shock.' Obviously there must be something in common between these three conditions.

In a particular study carried out by Dr. Weiss and his

## BOOK REVIEWS

*Human Gastric Secretion* Bengt Ihre. Acta Medica Scandinavica Supplement 95 226 pp Stockholm, 1938

Ihre has made careful quantitative studies of the enzymes, acidity and total chloride in the gastric juice of 24 normal and 70 pathologic cases. For this study he emphasized the importance of a choice of method in obtaining specimens which would prevent the loss of juice through the pylorus, the admixture of duodenal juice due to regurgitation in the stomach and the admixture of saliva. He used, therefore, two Rehfuß tubes combined in the double tube of Lagerlöf and Agren. With this tube in place he could obtain gastric and duodenal juices quantitatively and separately. The saliva was avoided by continuous suction from the mouth. The juices were collected by continuous suction and routinely fractionated in twenty minute periods. In order to get gastric juice after both humoral and neural stimulation, both histamine and insulin were used separately in every case. Insulin hypoglycemia was shown to be an excellent vagal stimulant. The determinations of acidity and total chloride were done electrometrically, and determination of pepsin according to the method of Willstätter and Waldschmidt Leitz.

Studying the primary acidity and the regulation of acidity in special experiments he obtained support for the theory of Pavlov of a high and constant primary acidity. He concludes that the regulation of acidity mainly takes place through back diffusion of hydrogen ions through the gastric wall in accordance with the theory of Teorell and through the secretion of mucus which acts as a diluter and to a slight degree as an acid-binder.

The normal material consists of healthy individuals showing the least possible effect of the acidity reducing factors. It was found that this was the case in individuals in the twenties, while with increasing age the acidity reducing factors become more and more effective and a strictly physiologic secretion gets more uncommon. The highest acidity and total-chloride values were found in the normal series, and here the rates of secretion showed comparatively greater variations than did the values for the acidity and the chlorides. The same acidity values were encountered in men and in women, but in women there was a tendency toward a lower rate of secretion and they showed hypersecretion less often than did men.

The study of the pathologic cases was limited to gastric and duodenal ulcers, chronic gastritis and finally pernicious anemia. All cases were studied from the clinical point of view and were subjected to gastroscopy. On the whole, individuals with gastric ulcers showed a normal rate of secretion, while in most of those with duodenal ulcers there was more or less marked hypersecretion. In chronic gastritis without ulcer the tendency was clearly toward hyposecretion. Higher degrees of acidity than normal were not observed, and he concludes that the concept of hyperacidity lacks actual foundation. The majority of the pathologic cases showed lowered acidity. This is due

to the greater effect of the acid-reducing factors in the pathologically altered stomach, that is, increased back diffusion of acid due to alteration of the mucous membranes. A correlation between total chlorides and acidity was noted when the acidity declined or disappeared the chlorides did not fall below 120 milliequivalents per liter. Lower values are unquestionably due to admixtures of saliva.

Pepsin secretion is greatly accelerated by the vagal stimulation occurring in insulin hypoglycemia. Usually the pepsin elimination then reaches values two to three times greater than those before the stimulation. He established upper and lower limits for normal pepsin secretion and the existence of hyperpepsinia and hypopepsinia. When the vagal tonus is altered, variations in pepsin elimination depend on the rate of flow of gastric juice. Histamine and caffeine, which stimulate the secretion of gastric juice but do not produce any change in vagal tonus, have no effect on pepsin production.

When studying the secretion of pepsin it is necessary to know the amount secreted during a certain period, for the mere concentration in a sample collected over a short period is of little value. In this respect pepsin differs from acidity, which is high when the flow of gastric juice is high while the pepsin concentration tends to drop under the same conditions. The behavior of pepsin resembles that of the enzymes in the pancreatic juice, while the gastric acidity acts like the bicarbonate in the pancreatic juice. In this study sixty minute collections were used to evaluate pepsin secretion.

Since histamine has no effect on pepsin production, it was only from vagal stimulation that the pathologic deviations in pepsin secretion became fully apparent. A great number of patients with gastric and duodenal ulcers and gastritis without ulcer showed pepsin secretion within normal limits. Different degrees of hypopepsinia were common features in gastritis, particularly in women it was much less common in ulcers. Hyperpepsinia and hypersecretion may occur independently of each other, they are, however, usually correlated although not in the sense of cause and effect. They were present simultaneously in chronic ulcers of the stomach and duodenum, particularly in the latter. Hyperpepsinia, like hypersecretion, was less common in women than in men.

*Trauma and Internal Disease A basis for medical and legal evaluation of the etiology—pathology—clinical processes—following injury* Frank W Spicer 593 pp Philadelphia, London and Montreal J B Lippincott Co, 1939 \$7.00

Dr Spicer states in his preface that this study was prompted by the many problems which arise daily in the various courts of law relative to the causation or aggravation of disease by injury. He disclaims any intention of writing a book on traumatic surgery, but observes that the more that is known of the pathological processes following injury the more intelligent will be the adjustment of claims. His primary object, then, is to aid those concerned with such adjustment by supplying an authoritative book of reference, and this has been accomplished by a compilation of cases and of the opinions of authorities from the literature, chiefly English and American. The twenty five chapters deal with injuries classified according to the physiological system and the anatomical region involved, with the addition of special sections dealing with the relation of trauma to particular diseases, notably tuberculosis, peptic ulcer, appendicitis, diabetes, exophthalmic goiter, leukemia, arthritis, syphilis, tumors and electrical

with the application of tourniquets to the limbs in collapse but advised strongly against it. He said it is, of course, of benefit in cardiac asthma. As for alcohol in treatment, Dr Weiss believes it should be more generally used since it is a good ready fuel and is also an analgesic. Hemoconcentration is of no value as an indicator of circulatory collapse, since there is no change except in the late stages. Likewise there are no changes in the chemical constituents of the blood except in late stages.

### WILLIAM HARVEY SOCIETY

At a regular monthly meeting of the William Harvey Society of Tufts College Medical School on Friday, April 14, in the Beth Israel Hospital auditorium, the speaker was Dr Philemon E Truesdale, of Fall River. Dr Truesdale chose as his subject Diaphragmatic Hernia.

The first part of the evening, Dr Truesdale read a summarizing review of the symptomatology of diaphragmatic hernia. There is interference with three of the most important body functions: circulation, respiration and digestion. Symptoms are characterized by their diversity and number. So far as the circulation is concerned, there is interference with the venous return to the heart, and the heart is moderately or markedly displaced, with torsion of the great vessels. Sometimes these conditions give no symptoms, but at other times there may be all the symptoms of cardiac disease. As the lungs are encroached on, hoarseness, a dry cough, air hunger, cyanosis and collapse may develop, besides other manifestations of pulmonary disease. The disturbance of the gastrointestinal tract leads to even more and various symptoms. Such symptoms are usually provoked by food immediately after ingestion, as are the circulatory and respiratory manifestations. The picture of intestinal obstruction may develop as a result of constriction of the colon at the diaphragmatic stoma.

Dr Truesdale made a distinction between eventration and hernia of the diaphragm. The former may be either congenital or acquired as the result of injury to or paralysis of the phrenic nerve. Both forms may co-exist.

Since the symptomatology is so complex, a differential diagnosis is often difficult until the barium or bismuth meal demonstrates the lesion by x-ray. A few cases were first diagnosed as tuberculosis of the lung. In acute pancreatitis the left diaphragm may be high, but the blood diastase is elevated, as it is not in eventration of the diaphragm. The symptoms may suggest heart disease quite strongly, or may lead to a diagnosis of enlargement of the thymus. In the very young, the cough may be mistaken for that of pertussis, or the gastrointestinal symptoms of obstruction may lead to a diagnosis of congenital atresia of the bowel. Gall bladder disease in general gives pain at midnight or later and is usually associated with certain diets, whereas diaphragmatic hernia usually gives rise to pain in the daytime and after any sort of meal. The pain is also more constant than it is in peptic ulcer.

Dr Truesdale continued to instruct and entertain for the remainder of the evening by going through his extensive series of cases of diaphragmatic hernia and by illustrating with lantern slides.

### NOTICES

#### SOUTH END MEDICAL CLUB

The next meeting of the South End Medical Club will be held at the headquarters of the Boston Tuberculosis

Association, 554 Columbus Avenue, Boston, on Tuesday, June 27, at 12 o'clock noon. Dr Oscar Auerbach, pathologist, Sea View Hospital, New York City, will speak on "Pathogenesis of Empyema in Chronic Pulmonary Tuberculosis" and will show lantern slides.

Physicians are cordially invited to attend.

JOHN B. HALL, M.D., Secretary

## ASCORBIC ACID REQUIREMENTS IN PATIENTS WITH PEPTIC ULCER\*

HARRY A. WARREN, M.D.,<sup>†</sup> MICHEL PIJOAN, M.D.,<sup>‡</sup> AND  
EDWARD S. EMERY, JR., M.D.<sup>§</sup>

BOSTON

THERE are several reasons for investigating the vitamin C nutrition of patients with peptic ulcer. It has been recognized for many years that the usual diets prescribed for patients with an ulcer may be deficient in ascorbic acid. Cases have been reported of the development of scurvy in patients who had followed such diets for a long time.<sup>1</sup> Furthermore, it has been reported that guinea pigs have developed gastrointestinal ulcerations on diets low in or devoid of vitamin C.<sup>2</sup> In a preliminary study,<sup>4</sup> one of us (H. A. W.) found that the blood plasma in 90 per cent of patients undergoing treatment for peptic ulcer gave a low value for this vitamin. Archer and Graham<sup>3</sup> have reported similar findings.

In a discussion of the cause for these low values, Ingalls and Warren<sup>4</sup> suggested three possibilities: namely an inadequate intake of vitamin C, the destruction of the vitamin in the gastrointestinal tract before absorption could take place, and an increased utilization of the substance by the tissues.

The present report deals with the daily requirement for ascorbic acid of patients with an active duodenal ulcer. Van Eekelen,<sup>6</sup> Heinemann<sup>7</sup> and Van Wersch<sup>8</sup> have found that normal persons when saturated with vitamin C utilize from 0.70 to 0.84 mg. of the vitamin per kilogram of body weight per day. These figures represent the optimal requirements and are considerably greater than is necessary to protect against scurvy. Göthlin, Frisell and Rundqvist<sup>9</sup> have shown that 0.4 mg. per kilogram of body weight per day is sufficient to prevent abnormal capillary permeability. Furthermore, Van Eekelen reports that smaller amounts of vitamin C are utilized by the body when the level of tissue saturation decreases. Beyond the point of saturation, any excess of the vitamin is rapidly excreted in the urine.

It has already been shown that in the presence of disease the body may utilize increased amounts of ascorbic acid. Heinemann,<sup>10</sup> as well as Heise and Martin,<sup>11</sup> has demonstrated that patients with tuberculosis utilize as much as two or three times the normal amount, hence it seemed desirable to determine the amount of vitamin C utilized by patients with active duodenal ulcer.

### METHOD

Previous work suggests that the amount of ascorbic acid in the plasma may not give a good index of the degree of tissue saturation and is of little value in showing how much ascorbic acid is used by an individual. The saturation test devised by Van Eekelen<sup>6</sup> and by Heinemann<sup>7</sup> appears to yield an accurate index of the tissue saturation and enables one to determine how much of the vitamin is actually utilized by the tissues. Therefore this method has been used in carrying out the present study.

The test consists of saturating the body with vitamin C, allowing some days to elapse, during which time the patient receives only minimal amounts of ascorbic acid, and determining the amount necessary to resaturate the body. It is considered that a state of saturation exists when a moderate dose of ascorbic acid produces a very definite excretion into the urine.

During the period of the test ascorbic acid may be lost in either of two ways: through utilization by the tissues or by excretion in the urine. The amount that is utilized by the body can be readily estimated by determining the amount excreted in the urine and subtracting this from the total amount to bring the tissues to the second saturation. The amount of ascorbic acid which the body requires per day is obtained by dividing the amount of the vitamin which has been utilized by the number of days through which the test was run. The final result is ex-

injuries Penetrating wounds and fractures, being manifest in their effects, are spoken of but briefly for the sake of thoroughness. Each chapter is thoroughly documented by references, and an adequate author and subject index is supplied

Any observer of the contemporary scene will agree that the prevailing viewpoint is that any illness, accident, misery or unhappiness is the fault of society and should receive material compensation—from financial heart-balm for unrequited affections, through physical trauma, to allegedly libelous injuries to reputations. In the field of trauma, it would appear that Dr Spicer has collected evidence to show that it may be responsible for practically every ill that flesh is heir to. He defines trauma as 'a single or repeated mechanical injury resulting in contusion, crushing or laceration of the tissues' (Ewing), but apparently accepts psychic trauma, as for instance in exophthalmic goiter. With our present knowledge, imperfect though it is, of the profound influence of the endocrine glands, of the hormones and of the sympathetic nervous system on the circulation and on cellular metabolism, it would be unwise to deny the possible effect on disease of trauma acting through these agencies, but some of the author's examples of the responsibility of trauma seem far-fetched. A few examples may be pertinent. A man falls 5 feet and lands on his sacrum, has brief unconsciousness, complains of pain in the neck and at autopsy, twenty two days later, there is demonstrated acute epidemic encephalitis, the injury is adjudged to be the cause (p 52). Is it not more likely that the intracerebral lesions of the incipient disease caused the fall? Narcolepsy may be the result of an injury antecedent by 'several years' (p 82). Torsion and gangrene of the omentum may be due to the exertion of putting up storm windows (p 290). Peptic ulcer may be caused by a contusion 'occasionally the violence involves a portion of the body distant from the abdomen, the indirect forces acting along the principles of contrecoup' (p 306). Quoting Osler and Kelly, 'Trauma plays a definite role in acute appendicitis, the length of time elapsing between the injury and the first symptoms being from none to two years' (p 366). 'Trauma may injure the graafian follicle or corpus luteum, without gross injury to the pelvic organs, sufficiently to cause many menstrual disorders' (p 430). 'Falls upon the feet may cause diabetes' (p 442).

This reviewer does not mean to suggest by these examples that the book is not written with sincerity, but it seems fair to say that Dr Spicer is presenting in the affirmative the case for the responsibility of trauma in causing internal disease. There are very few, if any, citations of authorities for the negative perhaps such are not to be found in the literature! Dr Spicer rarely presents his own opinion except as it may be inferred from his summaries of quoted authorities. This book should be an invaluable source book for physicians, patients, attorneys, clients, courts, industrial commissions and insurance companies. To the ten million persons who are said to suffer accidents in the United States every year, it will offer encouragement and aid in obtaining pecuniary relief in carrying the burden of illness. If conscientiously employed it will doubtless be a factor in promoting the just obligations of society to its members

*Industrial Surgery Principles, problems and practice*  
Willis W Lasher 452 pp New York Paul B Hoeber, Inc., 1938 \$6.00

Prof Lasher brings together in the earlier chapters the ideal setup for the handling of industrial cases requiring surgical treatment. He advocates a unit equipped accord-

ing to the size of the industrial plant and the nature of the injuries to which the employees are most liable, and a personnel adequate to give the service necessary. Typical forms on which careful records are to be kept are illustrated.

After consideration of general surgical conditions, the regional method is followed, beginning with finger and hand injuries and continuing with the other parts of the body, including a consideration of peripheral nerve injuries, bursas, fracture-dislocations, and so forth. The New York Labor Board's method of assessing losses as a basis for compensation for the various injuries is outlined. A number of admirable suggestions are made to aid in distinguishing between the three types of malingers which the author recognizes. Illustrative cases are cited to emphasize points he wishes to bring out.

Though necessarily brief, the recommendations for treatment are clearly given and are based on the experience the author has had over a number of years as the director of the Employers' Liability Assurance Corporation, of New York. As befits an official in that position he probably would be classed as an ultraconservative. In certain subjects, like that of hallux valgus, for example, his opportunity to follow the surgical treatment of that deformity in industrial cases has not perhaps been extensive, accounting for his advocacy of surgical measures, in cases deemed suitable for operative treatment, that are not generally employed and for a reason not commonly advanced. In discussing the diagnosis of knee joint lesions he records his experience with a method of examination which is all too little employed in this country, namely inflation of the joint with air to aid in bringing into high relief structures not otherwise clearly seen in an x ray film. The same method is followed in joints of the lower extremity, the spine and the pelvic girdle. The last few chapters he devotes to such matters as hernias, cranial and facial injuries, those of the abdominal and thoracic viscera, the jaw and the neck and a miscellaneous group. In an appendix, a well illustrated section is devoted to describing splints and certain tools commonly used in handling industrial accident work.

The book will be found very helpful to anyone engaged in this type of surgery and indeed it is worth having on the shelves of any practitioner's library

*Pediatric Symptomatology and Differential Diagnosis*  
Sanford Blum 500 pp Philadelphia F. A. Davis Co., 1938 \$5.00

A reviewer—unless he be an utter misanthrope—is always pained to find a book of which he can say not one kind thing, but he is so circumstanced here. A treatise of this sort, to be worth its salt, ought to be both up to date and thoroughly comprehensive in scope, and this is neither. One might almost suspect, indeed, that it had been held in manuscript since about 1913, so far do its matters and, conspicuously, its point of view lag behind the times. As a test for its degree of obsolescence, let anyone turn, for example, to the sections on pneumonia and tuberculosis. For the rest, there are many subjects omitted altogether, such as renal rickets, oxycephaly, osteopetrosis, Schüller-Christian's disease, acrodynia, erythroblastic anemia, undulant fever, nephrosis and trichinosis. Granted that these are all uncommon conditions, it is precisely the uncommon that is most likely to send a man to a specialized volume on diagnosis.

There are many books, of course, which would be the better for some revision, but this is so faulty in all respects as to convince one that no amount of revision could ever make it useful.

unable to absorb the drug when given by mouth. It was also found that these patients had been taking diets deficient in vitamin C. It is pointed out that the usual Sippy diet contains much less than the normal requirement of vitamin C. If it is desired to meet this deficiency it is easy to make up the vitamin C requirements by including in the daily diet the juice of one or two good-sized fresh oranges.

## FRACTURE OF THE FIRST RIB DUE TO MUSCLE PULL

## Report of a Case

ALEXANDER P AITKEN, M.D.\* AND ROBERT E LINCOLN, M.D.†

BOSTON

**F**RACTURES of the first rib unassociated with other fractures are very rare. Breslin<sup>1</sup> has recently reviewed the literature and found 27 cases, to which he added 5 of his own. Lane<sup>2</sup> states that fracture of the first rib can take place in only one of three ways, by indirect violence, the force being transmitted through the clavicle, directly by means of force applied from behind, or indirectly, by force being transmitted through the manubrium.

Although most of the reported cases have been due to one of these mechanisms, there are 2 cases in the literature in which the fractures were said to be due to muscle pull.<sup>3,4</sup> That fracture of the first rib can be due to muscle pull, particularly that of the scalenus anticus, is shown by the following case.

## CASE REPORT

The patient was a well-developed and well-nourished white man 29 years of age. He had placed on his head a load of cardboard weighing approximately 50 pounds. Steadying the load with his right hand, he had climbed three steps of a stepladder when it suddenly tipped to the left. Endeavoring to maintain his balance, he jerked his head forcibly to the right, and as he did so felt a snap in the left side of the neck, followed by severe pain, localized partly in the neck but chiefly over the posterior aspect of the left shoulder. He also experienced sharp pain radiating down the upper arm and the inner side of the forearm. With the onset of pain there developed immediate rigidity of the neck. Within 48 hours the acute pain subsided and the patient returned to work. The pain in the neck and shoulder and the stiffness persisted for the 1st week and then subsided. At the end of

the 3rd week he was symptom free. Twenty-six days following this injury the patient was in the act of pulling back a bedspread with his right hand when he again felt

FIGURE 1 Arrow points to fracture

a violent snap in the left supraclavicular fossa followed by extreme pain felt chiefly over the posterior aspect of the left scapula. Any motion of the body, especially respiration, made the pain excruciating and caused it to radiate

pressed in terms of the number of milligrams of ascorbic acid per kilogram of body weight per day

### RESULTS

Saturation studies were carried out on 5 patients with active duodenal ulcers. They had been on diets presumably low in vitamin C for periods ranging from one week to seven years preceding their admission to the hospital. During the period of study all received either the first- or fourth-week Sippy diet, together with alkaline powders or colloidal aluminum hydroxide. The following daily requirements were found to be necessary to maintain saturation in the five patients: 1.20, 0.91, 1.10, 1.02 and 1.05 mg of ascorbic acid per kilogram of body weight per day (Table 1).

TABLE 1 *Daily Requirements of Ascorbic Acid*

SUBJECT	AGE yr	SEX	WEIGHT kg	ASCORBIC ACID REQUIREMENTS	
				mg per day	mg per kg per day
B. L.	40	M	71.7	86.2	1.20
K. E.	50	M	54.7	57.6	1.05
R. E.	53	M	51.6	57.3	1.10
S. H.	43	M	59.2	60.9	1.02
M. A.	35	F	62.7	57.1	0.91

The average for this series was 1.02 mg. This is 20 per cent greater than Van Eekelen<sup>6</sup> and Heinemann<sup>7</sup> found for normal subjects. Since this investigation was started Heinemann<sup>12</sup> has reported similar studies of 4 patients with peptic ulcer. He also found a slightly higher requirement. The average of his 4 cases was 1.25 mg.

### DISCUSSION

The findings in this study, together with those of Heinemann, show that patients with peptic ulcer utilize somewhat more ascorbic acid than do normal individuals. However, this increased amount is so small that it can be supplied by the juice of one or two good-sized oranges.

The fact that these patients utilize a somewhat greater amount of ascorbic acid makes it all the more necessary that their diet shall contain an adequate amount of this substance. It is also true that many of the diets which are used in the treatment of peptic ulcer are low in this vitamin. We have assayed the amount of ascorbic acid in the first-week Sippy diet and found that it contained approximately 5 mg of ascorbic acid per day. The fourth-week Sippy diet contained approximately 15 mg. These amounts vary considerably depending on the amount and the freshness of the fruits and vegetables taken, however, they compare favorably with the estimated amount in such a dietary as calculated from published re-

ports on the amount of ascorbic acid contained in foods. According to the figures obtained by us, a person with a duodenal ulcer, weighing 150 pounds, utilizes about 70 mg of vitamin C a day. It seems evident that the low plasma values reported by others in cases of peptic ulcer may have been the result of a low intake. We have no reason to suspect that there was an abnormal destruction of the vitamin in the gastrointestinal tract, or any failure of absorption. Moreover, Heinemann administered the ascorbic acid by subcutaneous injection in 2 patients and found no difference in his results from the 2 other patients who received the vitamin by mouth. The inadequacy of the Sippy diet in maintaining saturation is also emphasized by the relatively large amounts of ascorbic acid needed to produce a second saturation in our patients. As much as 1800 mg of ascorbic acid was required to resaturate a patient after receiving a Sippy diet for three weeks.

The question now arises as to how much ascorbic acid should be given to a patient with peptic ulcer. It is fair to say that there is no evidence in the clinical picture of peptic ulcer, and more particularly in the rapidity of healing of these ulcers under the Sippy regime of dieting and neutralization of gastric acidity by alkalies, to suggest ill effects from this deficiency in ascorbic acid. In our opinion there is no reason for complicating the dietary problem of the ulcer patient by the addition of foods rich in ascorbic acid or of ascorbic acid itself, until it is demonstrated that ulcers will heal faster and recur less under higher ascorbic acid intake. However, if the physician desires to increase the vitamin C intake this can easily be done by recommending doses in excess of that utilized by the body for several days and then prescribing amounts which the individual will utilize throughout the period of active treatment. One can give 200 mg a day for a period of one or two weeks, depending on the previous intake of vitamin-C-containing foods, then 75 mg a day for two or three weeks longer. At the end of this time a patient should be able to obtain an adequate amount of vitamin from his diet. If for any reason those foods which contain a large amount of vitamin C, such as orange juice and tomato juice, are contraindicated, the deficiency can be made up by prescribing crystalline ascorbic acid.

### CONCLUSIONS

Studies have been made on the requirement of ascorbic acid by patients with peptic ulcer. It was found that 5 patients with duodenal ulcer utilized 20 per cent more ascorbic acid than do normal individuals. There was no evidence that they were

unable to absorb the drug when given by mouth. It was also found that these patients had been taking diets deficient in vitamin C. It is pointed out that the usual Sippy diet contains much less than the normal requirement of vitamin C. If it is desired to meet this deficiency it is easy to make up the vitamin C requirements by including in the daily diet the juice of one or two good-sized fresh oranges.

## FRACTURE OF THE FIRST RIB DUE TO MUSCLE PULL

## Report of a Case

ALEXANDER P. AITKEN, M.D. \* AND ROBERT E. LINCOLN, M.D.†

BOSTON

**F**RACTURES of the first rib unassociated with other fractures are very rare. Breslin<sup>1</sup> has recently reviewed the literature and found 27 cases, to which he added 5 of his own. Lane<sup>2</sup> states that fracture of the first rib can take place in only one of three ways, by indirect violence, the force being transmitted through the clavicle, directly by means of force applied from behind, or indirectly, by force being transmitted through the manubrium.

Although most of the reported cases have been due to one of these mechanisms, there are 2 cases in the literature in which the fractures were said to be due to muscle pull.<sup>3, 4</sup> That fracture of the first rib can be due to muscle pull, particularly that of the scalenus anticus, is shown by the following case.

## CASE REPORT

The patient was a well-developed and well-nourished white man 29 years of age. He had placed on his head a load of cardboard weighing approximately 50 pounds. Steadying the load with his right hand, he had climbed three steps of a stepladder when it suddenly tipped to the left. Endeavoring to maintain his balance, he jerked his head forcibly to the right, and as he did so felt a snap in the left side of the neck followed by severe pain, localized partly in the neck but chiefly over the posterior aspect of the left shoulder. He also experienced sharp pain radiating down the upper arm and the inner side of the forearm. With the onset of pain there developed immediate rigidity of the neck. Within 48 hours the acute pain subsided and the patient returned to work. The pain in the neck and shoulder and the stiffness persisted for the 1st week and then subsided. At the end of

the 3rd week he was symptom free. Twenty-six days following this injury the patient was in the act of pulling back a bedspread with his right hand when he again felt

FIGURE 1 Arrow points to fracture

a violent snap in the left supraclavicular fossa followed by extreme pain felt chiefly over the posterior aspect of the left scapula. Any motion of the body, especially respiration, made the pain excruciating and caused it to radiate

\*Instructor in orthopedic surgery Tufts College Medical School assistant to visiting surgeons Boston City Hospital

†Physician to Winchester Hospital Winchester Massachusetts

down the arm and the ulnar side of the forearm. The patient became faint and lay down. As he did so he felt a second snap in his neck. Immediately the acute pain in the shoulder subsided. However, rigidity recurred and motion of the head or arm caused pain in the supraclavicular fossa and over the posterior aspect of the shoulder, with some radiating pain down the ulnar side of the left arm and forearm. When the patient lay quietly, however, he had no pain but had some tingling in the fourth and fifth fingers of the left hand. X-ray photographs taken the day after the second attack of pain revealed a fracture of the first rib on the left side, at the point of insertion of the scalenus anticus muscle (Fig 1).

With immobilization of the head and neck all the acute pain disappeared in a few days. Flexion and extension of the head became normal and painless. Lateral flexion to the left caused pain only when the normal limits of motion were reached. Lateral flexion to the right, however, was completely limited for several days, and any attempt to elicit this motion caused sharp pain over the posterior aspect of the shoulder joint which radiated down the inner side of the arm. At the end of 4 weeks all symptoms had subsided and pain was produced only when the full limits of right lateral flexion were reached. In 7 weeks the patient returned to work and has been symptom free since then.

Because of the history of pain radiating down the left arm following sudden forced flexion of the neck to the right, it was at first thought that the patient was suffering from a scalenus anticus syndrome. The original x-ray photographs did not reveal the fracture of the first rib because of the overlying clavicle. However, films taken after the second onset of pain showed a distinct fracture.

Fractures of the first rib are unquestionably rare, and it is for this reason that this case is presented. Such fractures are not routinely looked for and are difficult to see because of the overlying clavicle. If an examination is made in cases where the patient complains of pain in the posterior aspect of the shoulder following direct or indirect trauma, it may be found that this lesion is not so uncommon as we now believe.

## TWENTY-FIVE NON-READERS\*

MILTON E. KIRKPATRICK, M.D.†

NEW YORK CITY

WE ARE slowly outgrowing the concept that the child who is slow in learning to read is either dull or mentally lazy. The psychologist has given us valuable assistance regarding reading disability, but there is still a greater contribution to make in remedial training. The visiting teacher and psychiatric social worker have indicated home situations which influenced school progress, and educators are now aware of the relation which exists between failure in learning to read and personality deviations which may develop later. Ideally, each child who experiences difficulty in learning to read should be subjected to an exhaustive analysis with the hope of finding the cause of the trouble. From a practical standpoint this is rarely done. To be sure, many schools give routine intelligence tests of one kind or another, but these are chiefly for the purpose of designating the group whose failure is due to intellectual limitations. The child of normal intelligence who is failing, particularly in reading, presents quite another problem. One authority<sup>1</sup>

states, "In Grade 1, 99 per cent of the pupils failing promotion were marked as failures in reading, in Grade 2 the percentage was 90, in Grade 3 the percentage was 68." The importance of reading in its relation to school failure cannot be questioned.

The present study is not presented as a thorough analysis of a group of non-readers, but is intended rather to call attention to the multiplicity of factors which enter into the problem. Without doubt, learning to read is the most important single accomplishment in the early formal education of the child. Its importance can scarcely be overstressed in its relation either to other subjects in the curriculum or to the broader aspects of living. There is some danger that we may become a nation largely influenced by things we see and hear, and that the vast realm of knowledge which reading makes available will be of decreasing importance as a cultural factor in our daily lives.

The 25 children (19 boys and 6 girls) selected for this study include practically the entire group of non-readers in the first, second and third grades in the school under consideration, excluding those of less than average intelligence. It was our

\*Part of a child guidance project conducted in the public schools of Webster, Massachusetts, by the staff of the Worcester Child Guidance Clinic.

†Formerly director of Child Guidance Clinic, Worcester State Hospital, Worcester, Massachusetts.

opinion that those children who had not learned to read because they were not yet intellectually ready constituted a special group about which we had some definite knowledge. Any child with an IQ under normal limits was therefore excluded. All children had had eye examinations by the school physician and visual defects, when present, had been corrected.

The co-operation of the teachers was assured from the beginning, as they found these non readers a source of considerable concern. In another study we had tried the questionnaire method of getting information, and this was abandoned because of the tendency on the part of the teacher to answer leading questions briefly and to avoid further elaboration. We therefore asked the teachers to write a report on each child, answering the following questions: Does the child like school? How does he get along with his classmates? Is he attentive in the classroom? Does he seem interested in classroom activities? What is his attitude toward failure? Do you consider him a leader or a follower? We established no criteria for the evaluation of these factors, and the objection may be raised that possibly more than the usual amount of subjectivity is involved.

The social workers interviewed the parents of the children, and without exception there was complete co-operation, not only in getting data for this study but in discussing findings and recommendations at its completion. The psychologist gave each child individual reading tests as well as hand-and-eye dominance tests. Each child was interviewed at least once by the psychiatrist after data obtained by others had been collected.

The following material is presented in order that a fair picture may be obtained of the family backgrounds of the children. Eleven fathers and eight mothers were foreign-born. This was in keeping with the population of the town concerned. A foreign language was spoken in ten of the twenty-four homes (2 children studied were from the same family). In three homes practically no English was spoken. One child never learned to speak English until he started school. Only three fathers and four mothers had an education above grammar school. Two parents were college graduates and two were illiterate. In eight families the parents had given some thought to the child's failure to learn to read and had decided that the school was to blame. Such an attitude is in no way conducive to learning on the part of the child. I suspect it occurs more often than we are aware.

It is often stated that reading, like speech, is born of necessity. We know that children will learn to talk when it becomes necessary for them to make their wants known. I have frequently

questioned the advisability of parents' reading to children, thereby relieving them of the necessity of reading for themselves. Nineteen of the children in this study were read to by some member of the family, 14 of these 19 were classed by their teachers as "followers." It would seem that this is an indication of a higher percentage of dependency than we should ordinarily expect. Our findings are not conclusive, but they indicate the general trend.

It was not always possible to obtain detailed information on early development because of the intellectual limitations of the parents. Retardation in teething, walking and talking was noted in 6 children. Ten children were very difficult to train in toilet habits, 1 was untrained until he was three and 1 until after four. The latter phenomenon indicates inadequate methods used by the mothers, but there are other implications as well, it suggests an early personality deviation. The relation between toilet training and disobedience and negativism is well known. These children had had experience in developing a negativist attitude toward the things which adults expected of them. This negativism is of potential importance in failure to learn to read.

Timidity was an outstanding characteristic in 13 children. Lack of interest in school was noted in 10. The indications are that the pattern of dependence, timidity and lack of interest has its genesis in the home, and that these children are lacking in the curiosity and emotional drive so essential to reading.

The psychologist submitted the following report as to grades. Four children were in Grade 1, 13 in Grade 2, 7 in Grade 3, and 1 in Grade 4. The average age of the entire group was eight years, corresponding to the third grade, but instead the average was about Grade 2, so that the children were practically one year retarded with respect to chronological age. Furthermore, the group had an average reading grade of only 1.46. In other words, the children did no better in reading than average six-and-a-half-year-old children. Apparently they had stopped learning to read, yet it is certain that lack of intelligence was not the cause. All the children were tested in order to determine hand and eye dominance. The results, as compared with those ascertained in similar and normal groups of children, showed a preponderance of mixed dextrality, that is right-handedness and left-eyedness. In this study we believe that mixed dextrality was not a significant factor. Readers are referred elsewhere<sup>2</sup> for a complete discussion of the relation between handedness and reading.

The averages for the types of error that these children made in reading are shown in Figure 1.

down the arm and the ulnar side of the forearm. The patient became faint and lay down. As he did so he felt a second snap in his neck. Immediately the acute pain in the shoulder subsided. However, rigidity and motion of the head or arm caused pain in the supraclavicular fossa and over the posterior aspect of the shoulder, with some radiating pain down the ulnar side of the left arm and forearm. When the patient lay quietly, however, he had no pain but had some tingling in the fourth and fifth fingers of the left hand. X-ray photographs taken the day after the second attack of pain revealed a fracture of the first rib on the left side, at the point of insertion of the scalenus anticus muscle (Fig 1).

With immobilization of the head and neck all the acute pain disappeared in a few days. Flexion and extension of the head became normal and painless. Lateral flexion to the left caused pain only when the normal limits of motion were reached. Lateral flexion to the right, however, was completely limited for several days, and any attempt to elicit this motion caused sharp pain over the posterior aspect of the shoulder joint which radiated down the inner side of the arm. At the end of 4 weeks all symptoms had subsided and pain was produced only when the full limits of right lateral flexion were reached. In 7 weeks the patient returned to work and has been symptom free since then.

Because of the history of pain radiating down the left arm following sudden forced flexion of the neck to the right, it was at first thought that the patient was suffering from a scalenus anticus syndrome. The original x-ray photographs did not reveal the fracture of the first rib because of the overlying clavicle. However, films taken after the second onset of pain showed a distinct fracture.

Fractures of the first rib are unquestionably rare, and it is for this reason that this case is presented. Such fractures are not routinely looked for and are difficult to see because of the overlying clavicle. If an examination is made in cases where the patient complains of pain in the posterior aspect of the shoulder following direct or indirect trauma, it may be found that this lesion is not so uncommon as we now believe.

## TWENTY-FIVE NON-READERS\*

MILTON E. KIRKPATRICK, M.D.†

NEW YORK CITY

WE ARE slowly outgrowing the concept that the child who is slow in learning to read is either dull or mentally lazy. The psychologist has given us valuable assistance regarding reading disability, but there is still a greater contribution to make in remedial training. The visiting teacher and psychiatric social worker have indicated home situations which influenced school progress, and educators are now aware of the relation which exists between failure in learning to read and personality deviations which may develop later. Ideally, each child who experiences difficulty in learning to read should be subjected to an exhaustive analysis with the hope of finding the cause of the trouble. From a practical standpoint this is rarely done. To be sure, many schools give routine intelligence tests of one kind or another, but these are chiefly for the purpose of designating the group whose failure is due to intellectual limitations. The child of normal intelligence who is failing, particularly in reading, presents quite another problem. One authority<sup>1</sup>

states, "In Grade 1, 99 per cent of the pupils failing promotion were marked as failures in reading, in Grade 2 the percentage was 90, in Grade 3 the percentage was 68." The importance of reading in its relation to school failure cannot be questioned.

The present study is not presented as a thorough analysis of a group of non-readers, but is intended rather to call attention to the multiplicity of factors which enter into the problem. Without doubt, learning to read is the most important single accomplishment in the early formal education of the child. Its importance can scarcely be overstressed in its relation either to other subjects in the curriculum or to the broader aspects of living. There is some danger that we may become a nation largely influenced by things we see and hear, and that the vast realm of knowledge which reading makes available will be of decreasing importance as a cultural factor in our daily lives.

The 25 children (19 boys and 6 girls) selected for this study include practically the entire group of non-readers in the first, second and third grades in the school under consideration, excluding those of less than average intelligence. It was our

\*Part of a child guidance project conducted in the public schools of Webster, Massachusetts by the staff of the Worcester Child Guidance Clinic.

†Formerly director of Child Guidance Clinic, Worcester State Hospital, Worcester, Massachusetts.

Helen's mother is a cripple, barely able to walk. The child's father, in his sixties, is not well and keeps house. The older children at home baby Helen and read to her, and she likes this very much. The home is not giving her adequate physical care or training, and we believe that it is not surprising that the carelessness apparent in the child's physical appearance should also be evident in her reading habits. It is interesting that the father blames the school for all Helen's difficulties.

**Recommendations** Drill calculated to correct the carelessness which we think is the most significant thing about her reading errors. Anything the school or the teacher can offer this child in the way of training in the amenities and in habits of order, neatness and good workmanship should be of value to her. While it is realized that what the school can do is necessarily limited, it is believed that in this case the school, because of the home situation, is a more important factor than it is in the case of the average child.

**Recommendations for the School Nurse** Helen is badly in need of dental care and has tonsils which are enlarged and should be removed. We think that the Health Department should give serious consideration to having his home supervised, perhaps by a state worker.

These reports were taken to the individual teachers and discussed with them. At the same time the teachers reported on the adjustment and progress of the children. Possibly one of the most valuable by-products of the study is the absolving of the teacher of blame for all the children's failures, with the result that she can attack the problem with added energy. Certainly the improvement that some of these children have

made can be directly attributed to the teacher's changed perspective and fresh efforts.

In conclusion, failure of this group of children to keep pace in reading appears to be a personality problem centering around emotional conflict and lack of maturity. They are the younger children in the family, have been read to by parents and older siblings and have developed dependent and submissive traits. Lack of interest in school indicates a willingness to continue in the dependent role. This may be influenced to some extent by the presence of negativism, which is a carry-over from the child's early training. We are giving an increasing amount of attention to the significance of conflict as an important factor in personality development. If conflict generates a sufficient amount of unhappiness and feeling of difference, it will influence the learning process as well as other aspects of the child's personality development. The reactions of this group are in keeping with our observations on the importance of conflict in similar age groups. Proof is lacking that the failures in learning to read are assignable to any specific cause. On the contrary, we must consider the multiplicity of factors which influence the personality in its attempts at adjustment, whether it be learning to read or some other adjustive processes vital to the individual.

## REPORT ON MEDICAL PROGRESS

### PHYSIOLOGY\*

HEBBEL E. HOFF, M.D.†

NEW HAVEN, CONNECTICUT

THE past year has been distinguished not only by advances in research and in the application of physiological principles to clinical problems, but also by the appearance of several publications of more than passing interest. The first of these is the new *Annual Review of Physiology*,<sup>1</sup> a worthy companion to the *Annual Review of Biochemistry*. Presenting as it does a broad view of the year's advances in physiology, it is a valuable complement to *Physiological Reviews* which undertakes to give an exhaustive survey of particular fields. The editors have wisely attempted to secure critical appraisal of the assigned topics, rather than a simple catalogue of work done, and

in a large measure they have been successful. The reviews by Bozler on muscle, Davis on electrical phenomena of the brain and cord, Eccles on the spinal cord and reflex action, and Bronk and Brink on bioelectrical studies of the excitation and response of nerve are particularly admirable in this respect, and are especially valuable for the light they throw, from the special viewpoint of their authors, on the common problems of excitation and transmission.

Even more recently has appeared the second edition of the classic *Sex and Internal Secretions*,<sup>2</sup> again under the editorship of Dr. Edgar Allen. Each of the three sections, dealing with the biological basis of sex, the physiology of the sex glands, germ cells and accessory organs and the biochem-

\*Laboratory of Physiology, Yale University School of Medicine.

†Associate professor of physiology, Yale University School of Medicine.

Ten types of errors were classified pronunciation of vowels (V), pronunciation of consonants (C), reversals (R), addition of sounds (As), omission of sounds (Os), substitutions (S), repetitions (Rp), addition of words (Aw), omission of words (Ow) and words whose pronunciation required aid from the teacher (WA). The children taken as a whole showed marked difficulty in four directions the pronunciation of vowels and of consonants, the insertion of extra sounds, and the pronunciation of many of the commoner words for which they demanded excessive help, the last-named obstacle was the most outstanding one. Objectively one might conclude that the last group was predominantly a help-seeking one, inclined to rely on others to conquer difficult situations.

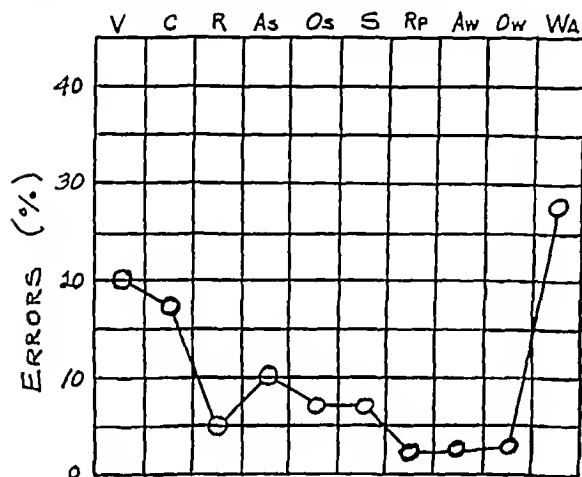

FIGURE 1 Profile of Errors for the Group

All these children were interviewed at least once by the psychiatrist, and 17 were classified as immature. For example, one child would not talk, another put his fingers in his mouth and left them there throughout the interview, answering questions by affirmative and negative movements of the head. Several of the children cried, and others were almost in tears, one stated that he liked to be the baby of the family and did not wish to grow up. Some mental conflict was elicited in 15 children. Three families showed no affection for their children, who felt rejected and unloved. One child was given to relatives. Two children had mothers in mental hospitals, and were not only teased about this by their classmates but believed that they would never see their mothers again. Two children had seen their fathers strike their mothers in a drunken rage. One child was not allowed to play with other children on the street and had no friends. Again it is difficult to say more than that from a psychiatric standpoint these children were essentially unhappy, their minds being preoccupied with conflicts which they could not understand, and

which interfered with their interest in learning. Spending only a few hours each day in the classroom, they were continually subjected to the molding influences of the home, whatever they might be.

The parents were interviewed at the school clinic by social workers, primarily to secure information about background, development, home conditions and attitudes, and with no thought of attempting treatment. Usually the mother was seen, but in several families where the father spoke better English he represented the parents, and in one case both father and mother came to the clinic. When the purpose of the study was explained to the parents, some became interested and asked for suggestions, some were apprehensive, in spite of assurances that no fault on their part or the children's was implied. With other parents, the social worker found herself interpreting some of the child's behavior, or suggesting that fewer comparisons be drawn between him and a precocious younger sibling. It was our opinion that later interviews with the parents might allay any anxiety which might have been aroused, help the relation between parents and school and in some cases modify parental attitudes that might be adversely affecting the child's schoolwork. The parents were promised that in return for their help we would later give them specific suggestions regarding their children.

The parents of all but 3 of the children came for the second interview. Some of them were no clearer about the purpose of the study than they had been in the beginning, and some were fixed in their belief that anything that was wrong was the fault of the school, or because the child had been sickly in infancy. A few had stopped reading so much to their children, or had given them more responsibility, and were pleased with the results, some were planning definitely for a change in their treatment.

After the director had made his general report to all the teachers in the school system, the teachers of the 25 non-readers requested individual reports and recommendations. The clinic staff went over its material, taking from the findings of the psychiatrist, the psychologist and the social worker what might be of practical help to the teacher. An example of such a report is as follows:

HELEN R		
ERRORS IN READING	%	DOMINANCE
Substitutions	25	Right-eyed
Addition of sounds	15	Right handed
Addition of words	14	
Consonants	11	
Vowels	9	
Reversals	9	

been found to be accompanied by changes in the T wave of the electrocardiogram similar to those evoked by increasing the serum potassium in experimental animals by intravenous injection of isotonic potassium chloride solution<sup>36-37</sup> The electrocardiograms of dogs with high serum potassium after adrenalectomy show similar changes<sup>38</sup> The observation that ischemic hearts lose potassium lends some support to the view that the alterations of the electrocardiogram in acute coronary thrombosis may be due in part to alterations in the serum or heart-muscle potassium<sup>39</sup> A high concentration of potassium in solutions perfusing coronary arteries is reported<sup>40</sup> to produce constriction amounting almost to occlusion The suggestion has also been made that changes in nerves and muscles induced by asphyxia may also be due to altered ionic concentrations<sup>41-42</sup>

An important new method for the study of the distribution of ions in the tissue is the use of radioactive isotopes by means of which the course of administered ions may be followed Hamilton<sup>43</sup> has already studied the absorption of radioactive sodium, potassium, chlorine, bromine and iodine in man and Brooks<sup>44</sup> has followed the accumulation of potassium in Valonia by this method It has also been found<sup>45-46</sup> that the radioactive salts behave in the body like the non-active material, thus disproving the old hypothesis of Zwaardemaak that the physiologic properties of potassium are due to its natural radioactivity

#### THE CIRCULATION

The fundamental observations of Goldblatt have established firmly the fact that permanent hypertension may be provoked by limitation of the renal circulation to a degree insufficient to produce local necrosis Sympathectomy does not relieve the excessive blood pressure<sup>47</sup> The evidence seems conclusive that a humoral mechanism is responsible for the elevated blood pressure,<sup>48-50</sup> and investigators have found pressor substances in normal kidneys, and in greater amounts in ischemic kidneys<sup>51-56</sup> The failure of permanent hypertension to develop when one kidney only is rendered ischemic and the onset of permanent hypertension when the normal kidney is later removed suggest strongly that a normal kidney can remove or inactivate the material responsible for the hypertension<sup>57</sup> Increasing the blood supply to the ischemic kidney by establishment of collateral circulation with the omentum has been reported to cure experimental hypertension<sup>58</sup> Reviews by Goldblatt<sup>59</sup> and Graybiel and White<sup>60</sup> are particularly valuable

Recent studies suggest that it is unlikely that the adrenal cortex is involved specifically in the

etiology of experimental hypertension, other than in the sense that the cortex is important in the maintenance of blood pressure in normal as well as in hypertensive states<sup>61-62</sup>

Viewed in the light of the enormous importance of adequate renal circulation, great interest attaches to the recent studies of the renal excretion in man of foreign substances such as inulin and Diodrast Smith and his co-workers<sup>63-64</sup> have shown that in the normal human being these substances are excreted by the kidneys in amounts to require a blood flow through the kidney of nearly 1500 cc of blood per minute (1050 to 1680 cc per minute in thirty-four observations on 15 subjects) Additional evidence indicates that this does not represent a maximum, but that vasodilating procedures may increase and vasoconstricting procedures may decrease these normal figures<sup>63-64</sup> Stated in terms of the figures usually given for cardiac output at rest, it means that from a third to a fourth of the blood ejected by the heart passes through the kidneys

There are various other experimental procedures which may evoke hypertension in animals Many of these are reviewed in the Dunham Lectures by Heymans<sup>65-67</sup> An important contribution to an allied subject, the hypotension of wound shock, is that of Freeman and his associates,<sup>70</sup> calling attention to the role of the sympathetic nervous system in precipitating the shock syndrome

Early observations by Bayliss<sup>71-73</sup> showed that stimulation of the dorsal roots produced a vasodilatation in the skin area supplied by the root stimulated He explained the phenomenon on the basis of a dichotomy of the afferent fibers in the skin, one branch going to a sense organ and the other to a blood vessel Normally this provided the anatomical basis for an "axon reflex" The sense organ being stimulated, impulses are sent along the fiber toward the spinal cord, when they reach the point where the axon collateral occurs they also travel down it to the blood vessel, which they cause to dilate This mechanism was later identified in the "triple response" by Sir Thomas Lewis, who found that the "flare" was mediated by such axon reflexes

Bayliss interpreted his own observations by suggesting that when he stimulated the dorsal roots, impulses traveled down the afferent fibers of the dorsal roots in the opposite direction to their normal course, that is antidromically Impulses thus eventually reached the axon collateral and produced dilatation Since that time a great number of investigators have been dissatisfied with this explanation, and have sought to detect in the dorsal roots true efferent fibers with cell stations

istry and assay of gonadal hormones, is worthy of a separate volume, and if the importance of each subject increases in the future as it has in the past, the sections will no doubt demand separate publication in future editions. As in the *Annual Review of Physiology*, the usefulness of the book depends on the evaluation of work rather than on the mere compilation of titles, and there is more than a suggestion that in both volumes, with certain notable exceptions, the value of individual chapters is inversely proportional to the length of the bibliography.

Among the more specialized monographs, Stevens and Davis's<sup>3</sup> *Hearing Its psychology and physiology* and Fulton's<sup>4</sup> *Physiology of the Nervous System* deserve mention. The first is the result of a fruitful collaboration between a psychologist and a physiologist, and effectively bridges the gap which often separates these fields. The book is remarkable for its emancipation from classical theorizations and for the ability of the authors to synthesize the material gained from study of small units and isolated phenomena into a unified account. The second is a welcome addition to the series "Outlines of Physiology," published by the Oxford University Press. This book presents a reasoned account of the functions of the cord and brain stem, it is historically well oriented, gives a judicious evaluation of the huge mass of modern work and is based primarily on the author's own investigations and collaborations in a wide variety of problems presented by the central nervous system.

#### THE ROLE OF IONS IN PHYSIOLOGIC PROCESSES

The past few years have seen an intensification of interest in the function of ions in a variety of physiologic processes, this is particularly true of the potassium ion. The studies of Ringer<sup>5-6</sup> long ago emphasized the importance of this ion in maintaining normal cardiac contractility and automaticity, and the influence of preponderance or deficiency of other ions. Howell<sup>7</sup> called attention to changes in potassium during vagal inhibition of the heart, determined the influence of low and high potassium on the action of the vagus on the heart and concluded that the vagus may inhibit that organ by changing the concentration of potassium. As long ago as 1900, Macdonald<sup>8</sup> suggested that the action current in nerves was caused by a difference in the concentration of potassium ions inside and outside the nerve membrane, and the recent work of Osterhout and his collaborators<sup>9</sup> and of Cowan<sup>10</sup> has supported this view. An influence of calcium and potassium on the recovery process in nerve, as shown by its effect on the afterpotentials, has also been demonstrated.<sup>11-12</sup> Potassium is also clearly implicated in neuromuscular trans-

mission and in muscular contraction. Its antitoxic action has been noted by several investigators,<sup>13-14</sup> and Brown and von Euler<sup>15</sup> have suggested that liberation of potassium ions is responsible for the phenomenon of post-tetanic potentiation, which is characterized in part by the facilitation of neuromuscular conduction by a tetanus. Bronk and others<sup>16-19</sup> have demonstrated that potassium has a similar facilitating influence on ganglionic transmission. Largely through the work of Fenn,<sup>20</sup> it is now well known that muscle loses potassium during contraction and regains it during rest. Wilson and Wright<sup>21</sup> have shown that intra-arterial injection of potassium salts increases the vigor of contraction in normal and denervated muscles, and Brown<sup>22</sup> has shown that in sufficient concentration they evoke tetanic discharge in the muscle. Wilder and his colleagues<sup>23</sup> have called attention to the importance of potassium in adrenal insufficiency, and have shown that an increased intake of potassium precipitates attacks. Serum potassium may or may not be elevated in Addison's disease, but is markedly elevated in experimental insufficiency. In such conditions of adrenal insufficiency the concentration of intramuscular potassium is found to increase markedly, while liver potassium fails to show any increase. Harrison and Darrow<sup>24-25</sup> have shown that the cure of adrenal insufficiency by the injection of the adrenocortical hormone or by administration of sodium chloride and sodium bicarbonate in hypertonic solutions is followed by return to normal of the intramuscular potassium. This action may be related to a direct effect of the hormone on the potassium metabolism within the muscle, or to alterations in the renal excretion of potassium during adrenocortical insufficiency. It is now well established that familial periodic paralysis is associated with low serum potassium during attacks. Ingestion of potassium, according to Aitken and others,<sup>26-29</sup> relieves and prevents attacks, while measures which lower serum potassium, such as the administration of insulin and glucose, produce attacks of paralysis. The function of potassium in the muscle may also be associated with carbohydrate metabolism. Injection of potassium has been found by Silvette, Britton and Kline<sup>30-31</sup> to produce a marked rise in blood sugar at the expense of liver and muscle glycogen. Kendall<sup>32</sup> reports that when cortical extract is given to a rat with high blood sugar resulting from partial pancreatectomy, a marked excretion of potassium takes place, while the administration of potassium greatly increases the glycosuria. The drop in serum potassium following insulin injections in man and animals has been recognized for some time.<sup>33-35</sup>

Only recently the increased level of serum potassium in Addison's disease and in nephritis has

the Harvard physiologists of the term "adrenine" in favor of "adrenaline." The very sound reasons for using "adrenine" and the great authority of the Harvard school were never able to dislodge "adrenaline" from public favor, nor has the campaign in favor of "epinephrine" been any more successful. In taking this step Dr Cannon has done much to encourage simplification of physiological nomenclature.

within the spinal cord which might mediate reflex vasodilatation. A great mass of material, reviewed some time ago by Sheehan,<sup>74</sup> yielded entirely in conclusive evidence. This year, however, Toenies,<sup>75</sup> working in Gasser's laboratory, obtained evidence of what seemed to be true reflex discharge emerging from the spinal cord via the dorsal roots. A stimulus being delivered to a group of afferent fibers discharges appeared in the dorsal roots after a period of latency comparable with that of other spinal reflexes. The classical characteristics of reflex discharge could be demonstrated: central latency, facilitation, after-discharge, and so forth. Most conclusive was the demonstration that impulses could be recorded in fibers other than those in which the afferent impulses traveled to the cord, on the same or opposite sides of it.

These remarkable experiments, which seemingly overthrow the classic doctrine of Bell and Magendie, which postulates that efferent or motor discharge occurs only via ventral root fibers, while afferent impulses enter only along dorsal root fibers, are too recent to have been thoroughly discussed by other workers. Preliminary accounts have only recently appeared describing certain differences in modifying conditions.<sup>76-77</sup> It appears that a subnormal temperature is required to obtain these reflexes, and that at body temperature they may not be found. The suggestion has been made that they are largely artefacts, in the sense that they represent the stimulation of the dorsal-root nerve endings rendered abnormally sensitive by cold, through the negative cord potentials known to exist following afferent stimulation and apparently responsible for the normal reflex activity following such stimulation. It seems to be a matter of some doubt, therefore, whether these reflexes can represent the functioning of the postulated "dorsal root efferents" in vasodilator reflexes, on the other hand, it is equally probable that study of these effects will shed a great deal of light on the normal physiology of reflex activity in the cord.

Some other evidence also suggests that the dorsal roots are not involved in reflex vasodilatation,<sup>78</sup> but the axon reflex has been further implicated in local vasodilating mechanisms. It is probably responsible for the reactive hyperemia in response to cold. Wybauw<sup>79</sup> has presented evidence of its activity not only in skin but also in muscle, where it may play a part in the spread of vasodilatation in the actively contracting muscle.

#### HORMONES

Much evidence has accumulated on the subject of the role of the autonomic nervous system in the genesis of ulceration in the gastrointestinal

tract. Many authors have claimed that lesions of the hypothalamus may produce ulcers, while others have been unable to confirm this. It is certainly true that not every hypothalamic lesion is followed by an ulcer, but on the whole the incidence of ulceration following such lesions is higher than in non-operated animals, or in those in which lesions of other regions of the brain have been produced. Since such hypothalamic lesions, at least theoretically, produce changes in the local secretion of sympathin or acetylcholine, attempts have been made to induce ulcers by the administration of these substances. Necheles<sup>80-81</sup> has now reported success using acetylcholine. Hemorrhagic ulcers were produced in all parts of the gastrointestinal tract in dogs by injections of this drug. Further implication of acetylcholine in the production of pathologic changes is claimed by Hall,<sup>8</sup> who has induced arteriosclerotic-like changes in the coronary arteries of dogs by repeated injections of this hormone.

What value these observations may have in regard to the genesis of ulcers and coronary disease in man is of course problematical. They serve, however, to bring again to the attention of physicians the importance of persistent imbalance of autonomic activity from reflex or psychic causes. It has been known for three quarters of a century that pronounced vagal reflexes affecting especially the heart may be obtained by irritation of the nasopharynx by vapors of ether, chloroform, ammonia, and so forth.<sup>82</sup> It is possible that irritation from tobacco smoke may also evoke these reflexes in susceptible subjects, and thus lead to excessive liberation of acetylcholine in the heart and gastrointestinal tract, where it may in time produce pathologic changes.<sup>84</sup>

Fisher, Ingram and Ranson<sup>83</sup> have recently summarized their studies of the nervous control of the secretion of the antidiuretic hormone. The hypophyseal hormone responsible for the prevention of diabetes insipidus is secreted by the pars nervosa, the median eminence and the infundibular stem. The secreting cells are themselves subject to nervous control from the supraoptic nuclei via the supraoptic hypophyseal tract, and an intact nervous mechanism is necessary for normal water metabolism. The presence of an intact anterior pituitary is necessary for the establishment of diabetes insipidus, or at least greatly facilitates its appearance, especially in the dog and cat. In the rat, presence of the anterior pituitary does not appear to be essential.

A definite spirit of progress is exhibited in a short explanatory note in a paper by Cannon and Lisak<sup>86</sup> entitled "Evidence for Adrenaline in Adrenergic Neurons." It marked the abandonment by

### *Medical Education and Medical Diplomas*

Dr Reginald Fitz, Suffolk, presented the report (Appendix No 6), which was accepted by vote of the Council

### *State and National Legislation*

An informal report was presented by Dr Charles C Lund, Suffolk. He pointed out the need for constant vigilance in legislative matters and suggested the necessity of presenting a positive program. Certain nuisance bills can simply be opposed and defeated but, in the case of certain definite trends of public feeling, it is necessary for organized medicine to propose definite constructive legislation. If unfavorable bills along similar lines are to be successfully opposed, in his opinion the responsibility for the protection of the public in medical matters rests with the medical profession. He called attention to the legislative bulletin, copies of which had been distributed at the meeting.

He pointed out that the committee had been successful in defeating all the bills which it had opposed, with the exception of three which have not yet been disposed of. The same success was not obtained with the bills which the committee favored. Three relatively minor measures were passed and the bills signed by the Governor. One of these, proposed by Dr Edward A Knowlton, Hampden, has removed the restriction previously imposed relative to membership in this society by appointees to the Board of Registration in Medicine.

The bills for annual registration of physicians and the licensing of hospitals were defeated. The bill to make changes in the Nurses' Registration Act has not been acted on, and the outcome is by no means certain since serious objections have been raised to many of its provisions.

It was reported that the Committee on State and National Legislation, in co-operation with the Committee on Public Relations, acting under the instructions of the Council passed at the meeting of April 26, has submitted a bill to authorize the formation of a non-profit corporation to insure payments of physicians' bills. The proposed bill must first be passed by the rules committees of the Legislature and, if allowed by these committees, it will be scheduled for regular hearings and action in the usual way.

Dr Lund then proceeded to discuss the action taken by the committee with reference to the Wagner Bill now before Congress. The chairman had been in communication with Senators Lodge and Walsh and was informed that the congressional

subcommittees would hold hearings on certain dates in May. Senator Lodge advised that a representative of the Society should be present. Dr Woodward, of the American Medical Association, gave similar advice. The chairman appeared before the subcommittee on May 26, 1939, after a series of conferences with representatives of the American Medical Association and with Senators Lodge and Walsh. His presentation to the committee differed somewhat from the arguments of the American Medical Association and at the end of the hearing the committee asked the Massachusetts Medical Society to assist in writing the proper kind of bill. The committee made a similar request to the American Medical Association.

He then proceeded to read a series of resolutions and referred to a statement by him which appeared in the *New England Journal of Medicine* for June 1, 1939, under "Legislative Notes."

The Council voted to accept the report as presented by the chairman. It then voted to approve the following resolutions:

RESOLVED, That the President nominate and the Council of the Massachusetts Medical Society elect a special committee to study and to have corrected, so far as possible, the practice of medicine by unregistered persons.

RESOLVED, That the Council of the Massachusetts Medical Society endorse the statement made by Dr Charles C Lund before the subcommittee of the United States Senate that is studying the Wagner Bill.

There was considerable discussion before the passage of the second resolution, part of which sought to delay action by the Council at this time and part of which was an explanation of the changes made in Dr Lund's presentation between the time it was read to the Committee on State and National Legislation and the Committee on Public Relations in joint session and the final form in which it was read to the senatorial committee.

The Council then considered a third resolution submitted by Dr Lund, which was as follows:

RESOLVED, That the Council of the Massachusetts Medical Society urge the Trustees and the House of Delegates of the American Medical Association to prepare a bill or bills and have them introduced into Congress for the following purpose: to correct so far as medically and socially sound and possible of legislative correction the evils that the American Medical Association admits exist and which the proponents of the Wagner Bill have hoped to correct by their bill.

There appeared to be a feeling on the part of some councilors that action on this resolution should be postponed until a subsequent meeting of the Council so as to permit further discussion and

## MASSACHUSETTS MEDICAL SOCIETY

### PROCEEDINGS OF THE COUNCIL

Annual Meeting, June 7, 1939

THE annual meeting of the Council of the Massachusetts Medical Society was held in the Municipal Memorial Auditorium, Worcester, on Wednesday, June 7. The President, Dr Channing Frothingham, Suffolk, called the meeting to order at 10 30 o'clock. There were 219 councilors in attendance (Appendix No 1).

The Secretary presented the record of the special meeting of the Council which was held in John Ware Hall, 8 Fenway, Boston, on Wednesday, April 26, 1939, as published in the *New England Journal of Medicine* for May 25, 1939. The record was declared approved.

One councilor having died since the last meeting, the President read the following obituary:

ALBERT F. LOWELL, M.D., of Gardner, died May 14, 1939, in his sixty-fifth year.

Born in Burlington, Vermont, Dr Lowell received his degree from the University of Vermont College of Medicine in 1900 and had practiced in Gardner since 1901.

Dr Lowell had been senior surgeon of the Henry Heywood Memorial Hospital and consulting surgeon at the State Hospital for the Insane at East Gardner, the Templeton Branch of the Walter E. Fernald School and the Peterboro (New Hampshire) Hospital.

His fellowships included the American Medical Association and the American College of Surgeons. He was a member of the Council of the Massachusetts Medical Society from June, 1923, until his death.

He is survived by his widow and one daughter.

The Council stood for a period of silence in respect to the memory of Dr Lowell.

A roll call showed the following nominating councilors to be present: W. D. Kinney, Barnstable; W. H. Allen, Bristol North; E. F. Cody, Bristol South; F. W. Snow, Essex North; J. F. Jordan (alternate), Essex South; G. L. Schadt, Hampden; L. N. Durgin, Hampshire; R. R. Stratton, Middlesex East; C. M. Roughan, Middlesex North; A. W. Dudley, Middlesex South; W. A. Griffin, Norfolk;

C. A. Sullivan, Norfolk South; W. H. Pulsifer, Plymouth; W. B. Breed, Suffolk; R. P. Watkins, Worcester; and C. B. Gay, Worcester North. (There were no representatives from the Berkshire and Franklin districts.) The nominating councilors retired to the Green Room for deliberation.

#### REPORTS OF STANDING COMMITTEES

##### Membership

The report (Appendix No 2), which was presented by the chairman, Dr H. Quimby Gallupe, Middlesex South, recommended that eleven fellows be allowed to retire, five allowed to have their dues remitted, four allowed to resign, three be deprived of the privileges of fellowship, four be restored to the privileges of fellowship, and four be allowed to change their districts without change of legal residence. The report was accepted by vote of the Council.

##### Financial Planning and Budget

The report (Appendix No 3) was presented by the chairman, Dr John Homans, Suffolk, and was duly accepted. The Council voted to approve the committee's recommendation that the annual salary of Mr Robert St. B. Boyd be placed at \$2500 per year.

##### Arrangements

Dr Richard P. Stetson, Norfolk, chairman, presented the report (Appendix No 4) of the committee, which was duly accepted by the Council.

##### Ethics and Discipline

The report (Appendix No 5) was presented by the chairman, Dr Robert L. DeNormandie, Suffolk, and was accepted by vote of the Council.

National Legislation, the President nominated Drs Charles C Lund, Earle M Chapman, Charles A Robinson, William A R Chapin and John A McLean. Dr Roger I Lee, Suffolk, moved the nomination of Drs Brainard F Conley and David L Lionberger. There being seven nominations, ballots were issued, and the President appointed Drs Lee, Homans, Shattuck and Blaisdell as tellers. The names of the nominees were written on the blackboard for consideration by the Council. After some discussion as to procedure, it was finally voted that the five men receiving the highest vote would be considered elected. It was voted that nominations cease, and the Council proceeded to ballot. The tellers retired to count the vote.

In connection with the retirement of Dr Franklin G Balch, Norfolk, as chairman of the Committee on Medical Defense and of Dr Robert B Osgood, Suffolk, as chairman of the Committee on Public Health, the Council voted to extend its thanks and appreciation to these gentlemen for their faithful services.

It was voted that the incoming president should nominate a fifth member of the Committee on Financial Planning and Budget since he is now a member of that committee and his election as president makes him a member *ex-officio*, thus creating a vacancy.

#### PROPOSED CHANGES IN THE BY-LAWS

The Council voted to approve certain amendments to the by-laws and to recommend their adoption by the Society at its annual meeting on June 8. (The complete text of these amendments will appear with the proceedings of the Society in the July 6 issue of the *Journal*.)

In the discussion of the individual amendments, the Council voted to transpose one sentence in Amendment No. 3 so as to avoid ambiguity. The Council voted not to approve of the proposed amendments which would change the time of appointment of the standing committees from June to October. There was some discussion about the length of time which fellows serve on committees. It was pointed out that the Committee of Arrangements has one new member appointed each year and the senior member retires. Dr Fitz stated that the Committee on Medical Education and Medical Diplomas is of the opinion that rotation is desirable.

#### INCIDENTAL BUSINESS

The appointment of twenty-five fellows to serve as voting members in the Associated Hospital Service Corporation of Massachusetts was confirmed by the Council. (The complete list will

appear as a part of the proceedings of the Society in the issue of July 6.)

The Council voted to confirm the appointments of three delegates and one alternate to the Convention for the Revision of the *Pharmacopoeia of the United States*, which will meet in Washington, District of Columbia, on May 14, 1940, as follows:

#### DELEGATES

Soma Weiss, Boston  
James H. Means, Boston  
Harold J. Jeghers, Brighton

#### ALTERNATE

William B. Castle, Boston

The President presented a letter from the Bureau of Legal Medicine and Legislation of the American Medical Association asking the Massachusetts Medical Society, at its annual session in Worcester, to voice a strong demand for an appropriation for the construction of a new building for the Army Medical Library and Museum in Washington, District of Columbia, and to appoint a committee to follow this matter through until an appropriation has been made.

Dr Shields Warren, Suffolk, discussed the importance of the suggestion made and emphasized the need of new quarters for the Army Medical Museum and Library since the collections contained therein are of such value to all types of medical research. He moved that the Council take the action requested. The motion was duly passed.

Dr Robert L. DeNormandie, Suffolk, presented a communication (Appendix No. 12) from the Advisory Committee of the Section of Obstetrics and Gynecology. On motion of Dr. DeNormandie, it was voted that the President appoint a committee of five to study the question of expert testimony in court cases and that it be empowered to confer with the Massachusetts Bar Association with the hope that rules and regulations may be drawn up in order to improve the situation.

Dr John M. Fallon, Worcester, read a statement (Appendix No. 13) concerning the progress which is being made in the negotiations between hospital authorities and certain groups of specialists in the medical profession.

Dr Henry M. Landesman, Norfolk, presented a communication to the Secretary enclosing a proposal for the organization of an insurance plan. The chair announced that this would be referred to the Committee on Public Relations for study.

The Council recessed for the Coting Luncheon from 1.20 to 2.30 p.m. On resuming the session the President announced that the only remaining item of business was to receive the report of the tellers appointed to count the ballots for the nomination of members to the Committee on State and National Legislation.

consultation with the American Medical Association

An amendment was proposed by Dr Michael A Tighe, Middlesex North, which would refer the whole matter of the Wagner Bill to a special committee which would report at the February meeting of the Council and that subsequently the findings would be referred to the House of Delegates of the American Medical Association Dr Lund pointed out the danger of delay and quoted from a telegram received by him from Senator Lodge Dr Tighe's amendment was put to vote and was lost

Dr Lund's original resolution was then presented and was approved by the Council

### *Public Health*

The report (Appendix No 7) of the committee, prepared by the chairman, Dr Robert B Osgood, Suffolk, was presented by Dr Francis P Denny, Norfolk The report was accepted After some discussion of a proposal that the Massachusetts Medical Society assist in conducting medical examinations of young people under the National Youth Administration, the Council voted to decline the invitation

### *Others*

There were no reports from the Committee on Publications, the Committee on Medical Defense and the Committee on Permanent Home

### REPORTS OF SPECIAL COMMITTEES

#### *Cancer*

There was no report from this committee

#### *Postgraduate Instruction*

The report (Appendix No 8) was presented by Dr Reginald Fitz, Suffolk It was accepted, and the Council voted to approve the recommendation that the Committee on Postgraduate Instruction be continued

#### *Physical Therapy*

Dr Franklin P Lowry, Middlesex South, presented the report (Appendix No 9) of this committee, which was accepted by vote of the Council

#### *Public Relations*

Dr Elmer S Bagnall, Essex North, stated that the report made by Dr Lund concerning the proposed legislation to insure payment of physicians' bills and his report on the Wagner Bill covered the activities of the Committee on Public Relations since its previous report

### *Industrial Health*

The President stated that this was a new committee appointed at the request of the American Medical Association No report was presented

### *Relations Between Physicians, Hospitals and Insurance Companies*

In the absence of the chairman, Dr William G Curtis, Norfolk South, Dr Henry M Landesman, Norfolk, the secretary, informally reported that four cases had been adjusted for physicians during the past year and that two others are in process Apparently all parties concerned are satisfied with the workings of the agreement He stated that the insurance companies are of the opinion that many physicians have not yet taken advantage of the authorization forms and consequently fail to obtain protection of their accounts in accident work The report was accepted

### *Restoration to Fellowship*

The Council voted to approve of the reports of committees recommending restoration to the privileges of fellowship of seven applicants and to accept the report of a committee which did not recommend restoration of one (Appendix No 10)

The Council voted to appoint committees to consider petitions for restoration to fellowship received from six individuals (Appendix No 11)

### REPORT OF NOMINATING COMMITTEE

Dr Edmond F Cody, Bristol South, presented the report of the Nominating Committee which recommended election to office for the ensuing year of the following

For president Walter G Phippen, Salem  
For vice president A Warren Stearns, Billerica  
For secretary Alexander S Begg, West Roxbury  
For treasurer Charles S Butler, Boston  
For orator W Jason Mixer, Boston

There being no nominations from the floor, it was voted that the nominations cease and that the Secretary be instructed to cast one ballot for the individuals named by the Nominating Committee. The Secretary reported that the ballot had been cast and the President declared the gentlemen named to be duly elected

### APPOINTMENTS OF COMMITTEES

The President proceeded to nominate and the Council to elect the members of the standing and special committees (The list will be published with the proceedings of the Society in the July 6 issue of the *Journal*)

As members of the Committee on State and

## APPENDIX NO 2

## REPORT OF THE COMMITTEE ON MEMBERSHIP

This committee recommends

1 That the following named eleven fellows be allowed to retire under the provisions of Chapter I, Section 5, of the by laws

Ahearn, Cornelius A, Jr, Salem, with remission of dues for 1939  
 Brunelle, Pierre, Lowell  
 Cragin, George A, Boston  
 Cusick, Thomas F, Taunton, with remission of dues for 1936, 1937, 1938 and 1939  
 Davis, Minot F, Boston, with remission of dues for 1936, 1937, 1938 and 1939  
 Galvin, William, North Adams, with remission of dues for 1939  
 Howard, Charles T, Boston, with remission of dues for 1936, 1937, 1938 and 1939  
 Milliken, Charles W, Fairhaven, with remission of dues for 1939  
 Sullivan, John T, Dorchester, with remission of dues for 1939  
 Wilcox, DeWitt G, Newton Centre  
 Young, Roy D, Arlington, with remission of dues for 1936, 1937, 1938 and 1939

2 That the dues of the following named five fellows be remitted under the provisions of Chapter I, Section 6, of the by laws

Borden, Charles R. C, Brookline, 1939  
 Dunscombe, William C, Porto Rico, 1939  
 Hamilton, Robert D, Newburyport, 1939  
 Plouffe, Bernard L, Webster, 1938 and 1939  
 Wilder, Edward W, South India, 1939

3 That the following named three fellows be allowed to resign under the provisions of Chapter I, Section 7, of the by laws

MacMillan, Andrew Louis, Jr, Concord, New Hampshire, with remission of dues for 1939  
 McLean, Emory A., Portland, Maine, with remission of dues for 1939  
 Pagliuca, Frank A., Boston, with remission of dues for 1937, 1938 and 1939

4 That the following named fellow be allowed to resign under the provisions of Chapter VII, Section 4, of the by laws

Pearlstein, Max, Braintree

5 That the following named three fellows be deprived of the privileges of fellowship under the provisions of Chapter I, Section 8, Clause a of the by-laws

Annis, Sumner B, Maynard  
 Karlsberg, Irving J, Hudson  
 Lyle, Eveline B, Brookline

6 That the following named four fellows be restored to the privileges of fellowship

Costa, Domizio A, Revere  
 Mahony, Francis R., Lowell  
 McCarthy, Humphrey L, Boston  
 Rushmore, Stephen, Newton Centre

7 That the following named four fellows be allowed to change their membership from one district society to another without change of legal residence, under the provisions of Chapter III, Section 3, of the by-laws

From Middlesex South to Suffolk

Burrage, Walter S, Newton

From Norfolk to Suffolk

Beaman, George B, Jr, Wellesley Hills  
 Hoyt, Lyman H, Brookline  
 Woodall, J Martin, Jamaica Plain

## APPENDIX NO 3

## REPORT OF THE COMMITTEE ON FINANCIAL PLANNING AND BUDGET

The Committee on Financial Planning and Budget makes the following recommendations to the Council

1 In the matter of an honorarium for the orator of the Society at the annual meeting, referred to the Committee on Financial Planning and Budget by the Council the committee recommends that it is not advisable to offer the orator of the Society an honorarium on account of his oration at the annual meeting

2. The committee recommends to the Council that the annual salary of Mr Robert St. B Boyd, originally \$2000 be raised during the present year to \$2500, that is, to \$500 more than was appropriated at the February meeting of the Council

JOHN HOMANS, *Chairman*

## APPENDIX NO 4

## REPORT OF THE COMMITTEE OF ARRANGEMENTS

The Committee of Arrangements takes this opportunity to present before the Council the tremendous importance of the work of Mr Robert Boyd in the planning and execution of the activities associated with the annual meeting. His energy, meticulous attention to detail and cheerful and diplomatic dealings with the many individuals and groups concerned with the annual meeting make his services to the Society of inestimable value.

It is of material interest to report that the revenue from commercial exhibits at the Worcester meeting in 1934 was approximately two thousand dollars, whereas it will probably be more than forty-eight hundred dollars this year.

The Committee of Arrangements takes pleasure in expressing to Dr Charles A. Sparrow and to his associates on the Worcester Committee for the Annual Meeting its

Dr Homans announced that the following fellows had been chosen

Charles C Lund  
Earle M Chapman  
David L Lionberger  
Charles A Robinson  
Brainard F Conley

The President then announced that he nominated Dr Charles C Lund as chairman of the committee. There being no other nominations, the Council voted to approve of Dr Lund's appointment as chairman.

The meeting adjourned at 2 35 p m

ALEXANDER S BEGG, *Secretary*

During the past year the committee has watched with interest the progress of the Society's efforts at postgraduate education. The program has created favorable discussion in other parts of the country and, on the whole, has proved successful. This year the Suffolk District Medical Society tried a new experiment. Each doctor licensed to practice and having an office in Suffolk County was invited to attend the course of lectures and those who expressed the desire were sent each week a postcard stating the subject of the week's lecture, the lecturer, and the time and place at which the lecture would be given. In this manner many doctors not hitherto approached by the Society were given opportunity and stimulus to receive systematic postgraduate instruction. Nearly two hundred attended the more popular sessions.

Another new effort in education sponsored by the Society in the past year was the Postgraduate Assembly. This proved unexpectedly popular and no doubt will be come increasingly so as time goes on. The Society is to be congratulated on having initiated so useful an undertaking.

EDWARD S. CALDERWOOD  
ARCHIBALD R. GARDNER  
GEORGE D. HENDERSON  
A. WARREN STEARNS,  
REGINALD FITZ, *Chairman*

## APPENDIX NO. 7

### REPORT OF THE COMMITTEE ON PUBLIC HEALTH AND THE SUBCOMMITTEE ON PUBLIC EDUCATION

The Committee on Public Health and the Subcommittee on Public Education beg leave to submit the following report.

The radio broadcasts under the auspices of the Massachusetts Department of Public Health and the Massachusetts Medical Society will continue each week into July. It is unfortunate that, owing chiefly to the popularity of the great American game of baseball, Station WAAB has twice felt it necessary to change the time of their delivery. Fan mail in satisfactory amount continues to be received.

The committee has been asked by the Public Health Committee of the Massachusetts Federation of Women's Clubs to provide speakers for several local group meetings of the Federation and to prepare several short articles for publication in its magazine on various medical topics suggested by the Federation. Thanks to the *pro bono* attitude of the members of the Massachusetts Medical Society, these requests have been satisfactorily met.

The committee has also arranged at the request of the Federation, speakers for three broadcasts sponsored by it and dealing with the present medical situation. The first of these was on the subject of "The Value of Organized Medicine to the People of the Commonwealth" by Dr. Dwight L. Siscoe, the second on "The Dangers of Socialized Medicine" by Dr. Elmer S. Bagnall, and the third on "Adequate Medical Care for the Indigent and Medically Needy" by Dr. Allan M. Butler. The Committee on Public Health believes that the friendly co-operation with this large well-organized group of women is desirable and advantageous to both the Federation and the Massachusetts Medical Society.

The Committee on Public Health held a meeting on April 25. At the meeting the thoughtful and laboriously prepared report of the Committee on Public Relations was considered. It was the unanimous opinion of the members of the Committee on Public Health that the

Massachusetts Medical Society should go on record as favoring the attempt to make available to the indigent and low income groups some form of voluntary non-profit insurance for the payment of medical services of physicians. It was also the unanimous opinion of the committee that the first step should be to secure the passage at the present session of the Legislature of an enabling act to make possible the submission of some plan approved by the Massachusetts Medical Society for such insurance. The committee believes that it is of extreme importance that the Massachusetts Medical Society should have a strong if not the controlling voice in working out any plans for voluntary non-profit insurance of this nature.

The Committee on Public Health at its last meeting held on May 29 voted to recommend the sponsoring of broadcasts during the coming year, under the heading of "Green Lights to Health," if possible with the co-operation of the Massachusetts Department of Public Health. It seems to the committee that larger audiences are obtained under this system than by any other method at present available.

Dr. Jakmauh, the health commissioner, has requested the Massachusetts Medical Society to arrange if possible for the examination of the young men and women in the Massachusetts branches of the National Youth Administration. The committee has had some communication with the commissioner's office, and I shall read a letter which has just come from Dr. Alton S. Pope, deputy commissioner of public health, written at the request of Dr. Jakmauh. (Dr. Denny read the letter.) You will see that this requires the careful medical examination of some 3000 young men and women ranging in age from eighteen to twenty-five. There would probably be various areas which would serve as headquarters—perhaps Boston, Worcester, Springfield and Pittsfield. They have asked the Massachusetts Medical Society to advise as to the type of examination and to estimate the cost of such care. The Committee on Public Health would like the opinion of the Council as to whether it is in sympathy with providing such services for the National Youth Administration under the auspices of the Massachusetts Medical Society, and if so, would it be willing to grant the committee authority to arrange for such examinations, in co-operation with the Department of Public Health, in the different areas by members of the Society living in the neighborhood, provided the remuneration for such examinations would be reasonably satisfactory. No figures as to remuneration have been given, although at the administration centers throughout the country a physician is employed on a part time basis and receives reasonable compensation for this service according to the amount of work performed in the way of medical care. We are asked only to provide for medical examinations, I gather, on the same sliding scale according to the extent and number of the examinations. The committee believes it is extremely important that such examinations should not be made unless facilities can be arranged for careful examinations.

ROBERT B. OSGOOD, *Chairman*  
GERALD N. HOEFFEL, *Secretary*

## APPENDIX NO. 8

### REPORT OF THE COMMITTEE ON POSTGRADUATE INSTRUCTION

The postgraduate extension courses for the academic year 1938-1939 ended on May 4; this completes the second year of co-operation with the Massachusetts Department

appreciation for the careful planning and enthusiastic work carried on by this group. To the initiative and co-operation of the Worcester committee is due the success of this meeting, and to them the Society owes its gratitude.

RICHARD P. STETSON, *Chairman*

## APPENDIX NO 5

### REPORT OF THE COMMITTEE ON ETHICS AND DISCIPLINE

Since our report to you at the February meeting of the Council, we have held two prolonged meetings.

We have given hearings to two fellows. The first was to a fellow who admitted paying the sum of \$200 to a selectman of a town in order to become the town physician. After hearing his story of the transaction, we asked him for his resignation from the Society, and he at once sent it in to the Secretary.

The second hearing was on charges of unprofessional conduct brought by a layman against a fellow. The layman consulted the fellow with the primary object of the termination of his wife's pregnancy because of her disturbed nervous and mental condition. The fellow sent the patient into a hospital, opened the abdomen, tied off the tubes and removed the appendix when she was between three and four months pregnant. He did not explain to the husband or wife that he had failed to terminate the pregnancy until after the patient suspected that she was still pregnant and the husband called up the fellow and asked him. The committee unanimously (the President of the Society sitting with us) agreed that the fellow's conduct was not ethical, and voted that the President send to him a letter of severe admonition. This has been done.

We have also considered twelve requests for information or complaints of unprofessional conduct of fellows. These have all been carefully considered at the meetings. The requests for information have been answered and the complaints against fellows have been adjusted.

ROBERT L. DENORMANDIE, *Chairman*

## APPENDIX NO 6

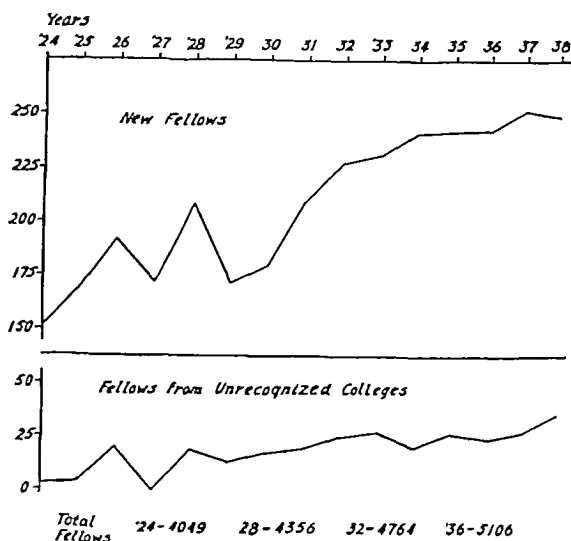

### REPORT OF THE COMMITTEE ON MEDICAL EDUCATION AND MEDICAL DIPLOMAS

During the past year this committee has held three meetings, has personally interviewed 80 applicants from schools unrecognized by the Council, and of these has acknowledged the diplomas of 50.

How to evaluate such diplomas continues to be the committee's most difficult task. Each applicant who presents his credentials almost invariably is able to produce several laudatory recommendations from a number of fellows. Many such letters are obviously solicited, are by no means confidential, and are not written according to the spirit of our by-laws.

By asking for information regarding the abilities and reputation of each candidate from his district secretary just before the meeting of the censors and after the list of names of new applicants has been published in the *Journal* we are able to obtain a few strictly confidential letters concerning applicants, and these are likely to prove informative. At best, however, the manner in which new fellows who are graduated from foreign or unrecognized American schools are elected to the Society is unsatisfactory.

During the past fifteen years there has been a distinct change in character of our fellowship. This is well illustrated by the accompanying graph. The Society grows

steadily in size and importance. It is evident that an increasing number of fellows who are graduates from foreign or domestic schools that we do not recognize are entering the Society each year. Two divergent views on this matter are held by the fellows of the Society in different parts of the State. There are certain fellows who believe that membership in the Society should be open to almost all physicians who are licensed to practice medicine according to the laws of the Commonwealth, and that no strong barriers should be built up to exclude any doctor with sufficient knowledge to pass our state-board examinations. At the other extreme are those who believe that membership in the Society should be strictly limited, and who criticize the work of our committee, saying that already we recognize too many diplomas each year and that we should be more critical.

To the committee the solution of the problem appears to lie entirely in the hands of the district societies. Unless fellows will give the committee confidential information proving the unfitness of any given candidate, we are compelled to accept as honest documents such letters of commendation as are sent in, and if, as of late has happened regularly, the latter far outnumber the former, we are led to assume that the majority of fellows are indifferent or actually favor an enlarged membership made up of an increasing proportion of men of uncertain educational background.

Another problem has recently arisen. This concerns the manner in which physicians who are graduates of foreign schools should be treated by the Society. Lately there have emigrated to Massachusetts from abroad, a number of mature, admirably trained, foreign doctors. They are entirely different from those younger men, unable to get into a reputable domestic school, who have gone abroad and have returned home again with a medical diploma of uncertain usefulness. How should these distinguished older men be treated? Should they at once be welcomed by the Society and admitted to its membership with all privileges or is it better judgment to accept them slowly? The committee has adopted the latter policy and for so doing has received harsh criticism from various quarters. We should welcome discussion on this point so that we may know how the Society as a whole feels about it.

Lewis Siegel, Somerville (Committee John A McLean, Edmund H. Robbins and Edward J Dailey)

Arthur J Taveira, New Bedford (Committee Thomas B Horan, Carl C Persons and Wilfred J Rousseau)

Restoration to fellowship was not recommended for the following former member

Horace G MacKerrow, Worcester (Committee Allen G Rice, Arthur W Marsh, Edwin R. Leib and Roy J Ward)

##### COMMITTEES APPOINTED TO CONSIDER PETITIONS FOR RESTORATION TO FELLOWSHIP

The following committees were appointed to consider the petitions for restoration to fellowship of the following six former members

For David Barron, Brockton

Alfred L Duncombe, Harrison A Chase and Frederick F Weiner

For Gerard Cote, Salem

Charles L Curtiss, Horace Poirier and John G Adams

For Irving L. Kushner, Somerville

Edmund H Robbins, Charles H Dalton and Louis J Grandison

For John F O'Brien, Fall River

Edward L Merritt, George C King and Emory C Kellogg

For Hyman S Queen, Brookline

Frank S Cruickshank, Charles J Kickham and Frederick Reis

For Harold S Tait, Palmer

Morgan B Hodskins, Sidney R. Carsley and Lucy G Forrer

##### RESOLUTION FROM THE ADVISORY COMMITTEE OF THE SECTION OF OBSTETRICS AND GYNECOLOGY

The Advisory Committee of the Section of Obstetrics and Gynecology of the Massachusetts Medical Society has at various times talked over the question of expert witnesses in court cases. It is realized that at times the testimony given has been at variance with the best medical knowledge. It suggests that a committee of five be ap-

pointed by the President to study this whole problem. It further suggests that this committee appoint a group sufficiently large to cover all the specialties, from which expert witnesses may be chosen to give testimony. It is suggested that these experts serve without remuneration, or if remuneration is received that it revert to the Society. It therefore wishes to present to the Council the following resolution

BE IT RESOLVED THAT, The President appoint a committee of five to study the question of expert testimony in court cases and to confer with the Massachusetts Bar Association with the hope that rules and regulations may be drawn up in order to improve the situation.

ROY J HEFFERNAN, *Chairman*,  
RAYMOND S TITUS, *Secretary*

#### APPENDIX NO 13

##### STATEMENT FROM DR. JOHN M. FALLON

As the Council knows, there has been debate for three years about the status of the anesthetists in hospital prepayment plans. The situation has been talked over several times in the Council, and the Committee on Public Relations was asked to investigate. This committee appointed a subcommittee consisting of Drs Dunbar, Blaisdell and Tighe. The subcommittee arranged a conference between representatives of the hospital administrators and the anesthetists to meet and settle on a mutually agreeable formula. This formula was finally arrived at last night by representatives of the New England Society of Anesthesiology and Dr Eugene Walker, of the Springfield Hospital, and Mr Frank Wing, of the Boston Dispensary, representing the Massachusetts Hospital Association and the Boston Hospital Council respectively.

These representatives, after discussion and rejection of a plan to pay the hospitals \$5.00 for each anesthesia given by a hospital employee, came to unanimous agreement on the following formula offered by the New England Society of Anesthesiology

We are opposed to the inclusion of anesthetists services under the benefits to be derived under hospital prepayment contracts, and further, opposed to the inclusion of the word anesthesia in the contract, inasmuch as anesthesia is a medical service. We recommend that hospitals which furnish anesthesia bill patients separately for anesthesia as for other extras.

These representatives of the hospital and anesthetists groups will report to their respective organizations, and intend to present a plan for definite action at the next Council meeting.

of Public Health, the United States Public Health Service and the Federal Children's Bureau in giving such courses. The total enrollment for the past year was 795. Details of attendance are shown in the attached table of statistics.

Clinical teaching in syphilis and gonorrhea has been established, under joint auspices of the Society and the government agencies, at the Massachusetts General Hospital and the Boston Dispensary. These clinics have been successful, it is planned to continue this teaching next year. A statistical report of these clinics is attached.

In accordance with the vote of the Council, at its meeting on February 1, 1939, the committee will prepare an outline of courses, in co-operation with the government agencies, and report concerning financial arrangements at the next Council meeting.

The committee wishes to report splendid co-operation from the members of the faculty who have carried on their teaching duties at a high level of efficiency. The committee wishes to express the thanks of the Society to them for their very splendid assistance.

The second annual New England Postgraduate Assembly will be presented on October 31 and November 1, 1939. So far, all the New England state medical societies, except that of Connecticut, have joined with our society in sponsoring this assembly. The program is almost completed, a list of prominent speakers from various parts of this country and abroad have been invited as guest speakers. Sir Thomas Lewis, of England, has already accepted our invitation to appear on the program. Programs will be mailed to all physicians in New England in the autumn.

It is recommended that the Committee on Postgraduate Instruction be continued.

FRANK R. OBER, *Chairman*,  
LEROY E. PARKINS, *Secretary*

#### APPENDIX NO 9

##### REPORT OF THE COMMITTEE ON PHYSICAL THERAPY

Until the last few years, there has been very little well directed education in physical therapy. For that reason, the great majority of physicians now in active practice have had little opportunity to appreciate the value of this branch of medicine. Early instruction in physical therapy was provided almost entirely by the manufacturers of apparatus for use in this field. Little criticism, however, can be accorded their work, undesirable as much of it was, for not until comparatively recently have any of our medical schools provided instruction in physical therapy—and some have not yet done so. Appropriate educational procedures can give the prospective physician at least an opportunity to realize something of the possibilities and limitations of physical therapy.

Many physicians seldom use the simpler forms of physical therapy which can be of definite value to patients, and very few have sufficient knowledge to use, wisely, complicated apparatus for this purpose.

To cope with these conditions, the American Medical Association and this society have attempted to provide assistance. During the past year, this committee has supplied speakers for medical meetings and has prepared and published with your approval a pamphlet to help acquaint physicians and medical students with this subject. A cinema has just been completed depicting the actual use of various types of simple and more complex forms of treatment in this field. Application for the showing of this cinema may be made to the chairman of this committee.

The committee earnestly requests members of the Massachusetts Medical Society to acquaint themselves with at least the simpler aspects of physical therapy and to disseminate information concerning this much neglected branch of medicine.

FRANKLIN P. LOWRY, *Chairman*,

##### REPORT OF COMMITTEE APPOINTED TO CONSIDER RESTORATION TO FELLOWSHIP

Restoration to fellowship was recommended for the following seven former members:

E. Olin Angell, Millbury (Committee Charles N. Church, William B. Clapp and Arthur A. Brown)

Parker M. Cort, Springfield (Committee Allen G. Rice, John M. Birme and George L. Steele)

Israel Kaplan, Salem (Committee J. Frank Donaldson, Leonard F. Box and Arthur W. O'Neil)

Edward Lopatin, Worcester (Committee Charles A. Sparrow, George C. Tully and Erwin C. Miller)

John T. H. Powers, Greenfield (Committee Lawrence R. Dame, Howard M. Kemp and Harry N. Howe)

cysts in the acromial end of the left clavicle. There was a small cystic area in the right maxilla.

On the fifth hospital day an operation was performed.

### DIFFERENTIAL DIAGNOSIS

DR. ALFRED O. LUDWIG: May we see the x-ray films?

DR. GEORGE W. HOLMES: These films are quite characteristic of what I would expect you to call it.

DR. LUDWIG: I expect them to be characteristic of hyperparathyroidism.

DR. HOLMES: This is a picture of the skull. The parts which are affected show decalcified bone. This shadow in the kidney is characteristic of the type of calcium deposit we see in these cases. The bones in the pelvis also show decalcification with multiple cysts and fractures. The findings are certainly characteristic of hyperparathyroidism. In these cases which have had an unsuccessful neck exploration the problem is to find the parathyroid tumor. Sometimes the roentgenologist can help. I have seen the tumor in one case, but I cannot see it here. The treatment was not given in this hospital. Dr. Hampton, will you point out the tumor?

DR. AUBREY O. HAMPTON: I think you can see it in this film taken before treatment, the original film taken in 1936.

DR. HOLMES: There is no doubt that there is a mass present, but I wonder how you could be sure it was not an enlarged thymus, for instance.

DR. HAMPTON: I would not know that it was parathyroid. It is a mass.

DR. LUDWIG: As Dr. Holmes said, the x-rays are characteristic of hyperparathyroidism. The data are quite consistent with that diagnosis. Here is a girl who has fractures and cysts in various bones, hypercalcemia, hypophosphatemia, and a tremendous increase of phosphatase, which ought to be between 4 and 6 Bodansky units and here runs up to 73 units. After she came into this hospital, calcium was looked for in the urine and there seemed to be an increased excretion. No mention is made whether there was increased excretion of phosphorus, although it is usually present in hyperparathyroidism. The story of several neck explorations is not an unusual one. Certainly quite a number of cases studied in this hospital had multiple operations done elsewhere without the tumor's having been found. It is interesting that a note is made in the second paragraph that one of the parathyroids showed adenomatous hyperplasia. There is a type of hyperparathyroidism which is caused by hyperplasia of all the parathyroids.

DR. TRACY B. MALLORY: We never saw a section from that gland, did we, Dr. Albright?

DR. FULLER ALBRIGHT: No.

DR. LUDWIG: There was an adenomatous tumor of one, but it seems that the main difficulty was that in the original operation the large mediastinal tumor was not removed. It presumably was an adenomatous parathyroid and was responsible for the trouble. It is evident that the cyst removed could not have been the cause of the difficulty because the blood chemical findings did not change essentially after the operation was performed.

This girl also had a slight amount of anemia, consistent with the disease, and some evidence of impaired renal function. A Mosenthal test showed a concentration of 1014. We should expect her to concentrate to about 1025 at her age without any difficulty. We know she had kidney stones and from the description, perhaps some intrarenal calcification as well. One might suspect secondary renal impairment which again is not unusual in long-standing cases of this disease. The large bone cysts are not uncommon in this disease. The phosphatase is proportional to the amount of bone involvement and when there is a great deal, as in this case, the phosphatase is correspondingly high. With very little bone disease the phosphatase may be normal. The only question is, Should anything else be considered in differential diagnosis other than a disturbance of the parathyroids, hyperplasia of a number of the glands, or tumor of one of them? I can see very little else that we should consider here. In older people senile osteoporosis may confuse one clinically but in this condition the calcium and phosphorus levels are usually normal. Paget's disease in older people may sometimes be confused with this picture. There is nothing in the x-ray to suggest that, and again the calcium and phosphorus levels help to differentiate as they are usually normal or slightly elevated in Paget's disease, while the phosphatase is elevated, and may be very high. Then, too, in Paget's disease the uninvolved bones are normal, whereas in hyperparathyroidism all the bones usually show some decalcification. Osteomalacia I do not believe need be considered. That is a condition in which decalcification of the bone is due either to a failure of absorption or to a decreased intake of calcium, and in that condition the phosphatase is increased, the calcium is low or normal, the phosphorus is low, and there is usually no increase in excretion of calcium in the urine. One does sometimes see multiple solitary cysts of bone, but they usually can be differentiated aside from the x-ray findings by calcium and phosphorus studies. Occasionally cases of pituitary basophilism or adrenocortical tumors, where there is osteoporosis,

## CASE 25261

### PRESENTATION OF CASE

A twenty-two-year-old single woman was admitted for study.

At the age of fourteen years the patient gradually developed pain in the left mid-thigh. Two months later she began to limp. A year later she entered an outside hospital where a diagnosis of cyst of the neck of the left femur was made. At this time she weighed 71 pounds and was 53 inches tall. A tumor-like mass was also noted in the left maxilla just above the second bicuspid and first molar teeth. The cyst of the femur was curetted. During the next three years she used crutches. She became quite thin. During the fifth year before admission she was operated on twice, once for the removal of a cyst of the jaw and five teeth, and another time for a cyst in the lower third of the right femur. Blood studies at that time showed the calcium to be 14.3 mg per 100 cc, the phosphorus 2.6 mg, and the serum protein 6.3 gm.

X-ray films showed cyst formation and decalcification of nearly all the bones in the body. No renal calculi were seen. A neck exploration was then done. This showed no lesion on the right side, but a nodule was found on the left which microscopically was said to exhibit "adenomatous hyperplasia" of a parathyroid. Two weeks post-operatively the serum calcium was 16.8 mg and the phosphorus 2.4 mg per 100 cc. X-ray therapy was then begun over the right and left cervical regions, including the upper two thirds of the chest. A total of 8712 r was given over a period of many months. Blood serum studies at monthly intervals showed that the calcium varied between 10.8 and 14.3 mg per 100 cc, the phosphorus between 1.1 and 1.7 mg, the protein between 6.0 and 7.4 gm, and the phosphatase between 24.5 and 33.9 Bodansky units. X-ray therapy was discontinued the next year. Following this the serum calcium ranged from 11.6 to 14.2 mg per 100 cc, the phosphorus from 1.6 to 4.3 mg, the protein from 6.8 to 7.8 gm, and the phosphatase from 18.4 to 73.6 units. Three years before admission a second neck exploration was done. At this time the pretracheal muscles were sectioned

and the thyroid was completely exposed on both sides. A large area extending from above the thyroid cartilage down into the substernal space was explored and both sides examined thoroughly by direct vision and palpation. No evidence of gland enlargement or suspicious tissue could be found. During the next two years she suffered from no significant symptoms. Her serum calcium and phosphorus levels remained essentially unchanged. Eight months before entry a cyst developed in the right maxilla and gradually increased in size. Six months later x-ray films showed a tumor in the region of the right antrum but no bone destruction. The basal metabolic rate was +10 per cent. The serum calcium was 15.2 mg per 100 cc, the phosphorus 2.5 mg, the protein 6.4 gm, and the phosphatase 26.3 units. A Mosenthal test showed the urinary specific gravity to vary from 1.009 to 1.014. She entered this hospital for further study.

Physical examination showed a puerile but well-proportioned girl weighing 85 pounds, and measuring 59 inches in height. There was a large cyst in the right maxilla which appeared to extend into the right antrum. The thyroid gland was not palpable and there were no nodules in the neck. There were a few light-brown pigmented areas over the chest and abdomen measuring up to 3.5 cm in diameter. The breasts were small. Examination of the chest was negative. The blood pressure was 118 systolic, 78 diastolic. The genitalia were normal. The extremities showed bowing of both tibias. The left leg was slightly shorter than the right.

The temperature was 98.6°F, the pulse 120, and respirations 25.

The urine showed a specific gravity of 1.020, 20 to 30 white cells per high-power field, 3 to 5 red cells, and no casts. There was a large amount of calcium by rough tests. The blood showed a red-cell count of 3,900,000 with 70 per cent hemoglobin. The nonprotein nitrogen of the serum was 20 mg per 100 cc, the calcium 14.5 mg, the phosphorus 2.0 mg, the protein 6.8 gm, and the phosphatase 23 units. A phenolsulfonephthalein kidney function test was normal.

X-ray films showed generalized decalcification of the bones and scattered cystic areas. There was an old probable pathologic fracture of the neck of the left femur with coxa vara deformity. There was a large stone in the left kidney pelvis with several small stones in the calices and one small stone in the lower pole of the right kidney. Chest films showed a mass 5 by 2.5 cm in the right upper mediastinum displacing the trachea and esophagus slightly to the left. There were small

## ANATOMICAL DIAGNOSES

Hyperparathyroidism

Adenoma of the parathyroid gland

## PATHOLOGICAL DISCUSSION

DR. MALLORY The ultimate prognosis on this case depends on two factors first, the slight possibility that she will develop another parathyroid adenoma, or a large recurrence of this one, and, second, the degree to which her kidneys have been permanently damaged. It is too early to assess this last factor accurately in her case.

## CASE 25262

## PRESENTATION OF CASE

A forty-three-year-old married woman was admitted complaining of difficulty in swallowing.

Nine years prior to admission she first experienced a sharp stabbing pain between the shoulder blades on swallowing large mouthfuls of food. During the next four years she had about four similar attacks. Five years before entry the pain on swallowing occurred more frequently. She visited an outside hospital where x-ray films were reported negative. Subsequently she was essentially free from pain until about one year before admission when the pain gradually became quite constant with the swallowing of solid food. Two months later she noted stabbing pains between the shoulder blades, along the sternum, and in her esophagus each time she swallowed. These pains came on soon after going to bed and lasted throughout the night. The following day she visited her physician who advised that the basal metabolic rate be determined. This was low and thyroid treatment was started. Four months later she began to notice a dry feeling in her throat and esophagus when she attempted to swallow. She was found to be anemic and iron therapy was begun. Three months later she complained of difficulty in swallowing air, belching, and difficulty in breathing. X-ray films now showed a constricting lesion in the esophagus. Esophagoscopy done six weeks before admission showed a firm, red, slightly nodular mass at a point 30 cm from the incisors which completely obstructed further passage of the esophagoscope and appeared to encircle the esophagus almost completely. Several biopsies taken from this area were negative. Two weeks before entry another esophagoscopy was done and a number of more satisfactory biopsies taken. The pathological report on these was leukoplakia. Following these procedures the patient was nauseated and vomited. She regurgitated everything eaten. Physical examination showed a well-developed,

fairly well-nourished woman in no acute distress. Examination of the neck was negative. The heart was slightly enlarged to the left. The blood pressure was 112 systolic, 68 diastolic. The abdomen was slightly tender in the right lower quadrant. Pelvic examination was negative except for a reddened cervix and thick yellow discharge. Rectal examination was negative.

The temperature was 98°F, the pulse 70, and the respirations 18.

Examination of the urine was negative. The blood showed a red-cell count of 4,180,000 with 80 per cent hemoglobin and a white-cell count of 5800 with 62 per cent polymorphonuclears. The non-protein nitrogen of the blood serum was 17 mg per 100 cc., chlorides 98.5 milliequivalents, protein 7.2 gm per 100 cc. A blood Hinton test was negative.

An x-ray film of the chest was negative. A barium examination of the esophagus showed obstruction which started opposite the seventh dorsal vertebra and extended downward a little more than 4 cm. Within the area of obstruction there was an irregular but constant pattern suggesting ulceration. The obstructing lesion reached far upward posteriorly. It was annular for a distance of 3 cm. The lower edge of the lesion was very clear cut. No soft-tissue mass was visible within the area of abnormality. The esophagus below the lesion appeared perfectly normal. Above the lesion it was dilated.

On the third hospital day another esophagoscopy was done.

## DIFFERENTIAL DIAGNOSIS

DR. MILTON H. CLIFFORD In summary, this is a woman who apparently has had a lesion in the esophagus, or extrinsic to it, for nine years but showed nothing by x-ray some five years ago and whose symptoms have progressed rapidly only within the last year. At the present time the patient has an annular lesion with posterior extension in the esophagus. There is no reason to suppose that the lesion is primarily extrinsic to the esophagus—no soft-tissue masses being visible. Any lesion must be one that has been present over a long period of time.

I should like to see the x-ray films.

DR. RICHARD SCHATZKI There are no signs of tuberculosis or pressure on the vertebrae. This is the small area at the junction of the middle and lower thirds with complete destruction of the mucosal relief. There is shelf formation at the upper end of the lesion with slight dilatation of the esophagus above the lesion and normal esophagus below.

DR. CLIFFORD What are the possibilities of a

decalcification, and a disturbance of the calcium and phosphorus metabolism, may be confused with hyperparathyroidism, but there are many other features characteristic of these conditions that are not present here, such as obesity, hypertension, hirsutism and red, striated skin. I do not see how one can reach any other conclusion but that this is a case of hyperparathyroidism. I believe that in this case there was a tumor in an abnormally situated parathyroid gland in the mediastinum, where a number have been found in the past.

DR. HOLMES: I have now found out the secret to this case and I think it might be worthwhile to point out some additional factors. This is the film that was taken before the patient came to this hospital. We realize that it was taken with the patient lying on her back and at a fairly close target distance. This shadow which I was afraid might be artefact evidently represents the tumor. It is very much magnified. Following this the patient had a series of x-ray treatments. We have no proof that they reduced the tumor—they may or may not have. The tumor is present in this second film and appears very much smaller, but the way the film was taken and the target distance might account for the apparent diminution in size.

DR. ALBRIGHT: This of course is a perfectly classical case of hyperparathyroidism and I think the forty-first in our series. It is interesting that each case teaches something new. We learned one thing from this case. If you look at the stone by x-ray, it has the appearance of a snowflake with radiation from a central point. We did not know what type of stone this signified. We thought, having seen a stone with this same appearance in another case of hyperparathyroidism, that such a structure might be seen only in that condition. We are in the habit of considering all hyperparathyroid stones as composed of calcium phosphate. We therefore jumped at the conclusion that it was calcium phosphate and thought it might be dissolved by citrate solutions introduced from below. After three days of attempted dissolving, there was no change. In the meantime we took out a stone of the same type from another patient and it proved to be pure calcium oxalate. We found after an operation in the present case that the stone we were trying to dissolve was also calcium oxalate. That explained our lack of success. We now know that all star-shaped stones are made up of calcium oxalate. This is very important since the treatment of a stone depends on its chemical composition.

The operation was done by Dr. Oliver Cope.

He entered the upper mediastinum, found the tumor easily and removed it. He left a small piece. When one has a hyperparathyroid tumor with marked bone involvement one does not take out the whole tumor at one time. She had moderate postoperative tetany.

DR. MALLORY: Would it be a fair assumption, with the marked change in the calcium and the phosphorus, to say that the tumor must be a large one?

DR. ALBRIGHT: We never have seen a very small tumor causing as marked disease as this.

DR. MALLORY: So that if it had not been found in the course of two neck explorations it must have been in the mediastinum, assuming that the operator was competent?

DR. ALBRIGHT: Perhaps, but they do get behind the esophagus. A parathyroid can be fairly large and still be missed. They mold themselves in the neck behind and around the other structures and do not cause them to bulge.

A PHYSICIAN: Do you think material removed at the first operation was hyperplastic parathyroid?

DR. ALBRIGHT: No, I think it was normal.

A PHYSICIAN: They said it was embedded in fat.

DR. ALBRIGHT: It certainly was not hyperplastic, if there was any fat.

DR. HOLMES: This is the second case in which repeated explorations have failed and yet the tumor was visible all the time in the x-ray films.

DR. ALBRIGHT: In the best plates, those with barium in the esophagus, you can see the outline of the tumor very easily.

A PHYSICIAN: Do you think the calcium oxalate stone has anything to do with hyperparathyroidism?

DR. ALBRIGHT: Yes. There is no reason why a calcium oxalate stone should not form in this condition. We have one other case.

DR. MOSES S. STROCK: May I say a word, Dr. Mallory? This case, it seems to me, presents a typical history of well-advanced hyperparathyroidism so far as the teeth are concerned. Several years ago she had her teeth removed. If her dental films could be shown they would present all the signs previously described here as being associated with hyperparathyroidism. I think any member of the x-ray department could make a diagnosis from the dental films alone.

## FAMILY TRADITIONS IN MEDICINE

An article in the *Boston Herald* last month, concerning the medical tradition in the Kittredge family, of North Andover, brings immediately to mind other medical families of note. Nine successive generations in the Kittredge family, however, beginning in 1660 when Captain John Kittredge, an irregular but apparently able practitioner, fled from England to this country, and coming to date with Dr. Joseph Kittredge who celebrated his eighty-first birthday on May 21, seem to constitute an all-time record.

We are mindful of a number of medical families that have won our respect and admiration, although, indeed, the same might be said of the other professions and the trades and businesses as well. Various cities have had their own honored medical names where the tradition of service has

gone into three, four and even five generations, we point with pride to our Warrens, our Jacksons and our Shattucks, to our Cabots and our Minots and others—solid rocks on which the foundations of medical progress in our community were largely laid.

In some instances a number of individuals of varying ability but of unquestioned integrity have served to carry on the family tradition, in other cases a father and a son have each been of such prominence that a sort of medical halo has seemed to place itself on the family name in their behalf.

There is a nobility about this pursuit of a family tradition, whether it be in medicine, in the law or in trade, that seems to result from the unswerving loyalty of each successive member to that tradition, and the desire of each to acquit himself well in the eyes of his predecessors and of his world. In the accomplishment of this object, ability in general must have been inherited, as well as ambition of the truest and consequently of the most modest type, the most important incentive, however, must have been the constant association with a respected mode of life.

It is the modern exemplification of the old guild system. In this way the art of making the world's most marvelous imitations of flowers has been developed and carried on until a successor was lacking, the spirit of integrity and honor associated with a family name has been made part of the tradition of every business from banking to marketing, generations have lived and died in the honorable pursuit of the law and in the ministry of the church.

The family calling can be a splendid tradition, but it can be so only as the result of freedom of choice. Give a son every opportunity to see the noble side of a profession, and give him an opportunity to see it nobly followed. Let him know also the disagreeable side—the fatigue and the discouragement and the disappointments. Then let him make his choice, and support him in his decision.

A considerable degree of idealism, as well as a good deal of glamour, attaches itself to this following in the family footsteps, but it cannot be forced

benign lesion in the wall of the esophagus? You would say the mucosal pattern is destroyed?

DR SCHATZKI It is completely gone

DR CLIFFORD The possibility of a benign lesion's having been present for a good many years with the recent development of a superimposed carcinomatous process must be considered. There is no evidence to make us think of a neurofibroma. Lymphoma is possible, but there are no other signs such as enlarged lymph nodes, liver or spleen and it is rather a long time for lymphoma to be localized in one spot. Syphilis is a dim possibility, but again it is a long time. Whether the signs of chronic endocervicitis mean gonococcal infection or not, I do not believe is important except that its presence might further suggest syphilis. The Hinton test, however, was negative. A myoma would be a very unlikely possibility. There has been no sign of bleeding at any time. A sarcoma I should consider to be more likely intrinsic, and also to have shown more definite signs of obstruction earlier in the nine years. My final guess would be a carcinoma possibly developing on top of a benign lesion. As a second guess I would mention a leiomyoma.

DR EDWARD B. BENEDICT We thought from the beginning in this case that we were dealing with carcinoma of the esophagus, but we had a great deal of difficulty in proving it because the lesion was rather small and showed only slight nodular formation. On the third attempt we did get a positive biopsy of carcinoma. I should like to point out that, in women, carcinoma of the esophagus is apt to run a long course and occur at an early age with prolonged so-called pre-cancerous symptoms. This patient had no metastatic disease, so far as could be determined was a good operative risk and an esophagectomy was performed by Dr. Edward D. Churchill.

DR TRACY B. MALLORY A segment of the esophagus was completely removed in this patient, she has safely recovered from that operation and is on the ward waiting for reconstruction of a new esophagus.

DR. EDWIN HAMLIN The operation was planned with great care by Dr. Churchill and was suc-

cessful. He first performed a jejunostomy for feeding, then an esophagostomy, to draw the upper end out through the neck, and at the third stage he removed the section of esophagus with the growth and freed up the distal portion of the esophagus down to the diaphragm. At the fourth stage he removed the distal esophagus from the thoracic cavity and brought it out through the abdominal wall.

#### CLINICAL DIAGNOSIS

Carcinoma of esophagus

#### DR CLIFFORD'S DIAGNOSIS

Carcinoma of esophagus, ? developing on a benign lesion

#### ANATOMICAL DIAGNOSIS

Epidermoid carcinoma of esophagus, Grade II

#### PATHOLOGICAL DISCUSSION

DR MALLORY The tumor was about 5 cm in length and had not yet quite completely encircled the esophageal wall, it went about three fourths of the way around. There was a relatively small area of ulceration. There was a good margin of normal esophagus at either end of the resected segment. On the other hand the tumor had invaded through the muscular layer and we found tumor in the perineural spaces and lymphatics, so that it is distinctly doubtful if it has been entirely removed.

A PHYSICIAN Has anyone looked up the literature on surgical treatment of cancer of the esophagus? How many successful cases have been reported?

DR BENEDICT About thirty have been successfully removed and several patients have survived for one or two years. Torek's first case in 1913 lived for thirteen years. She was a woman of sixty-seven at the time of the operation, and died of pneumonia at the age of eighty.

DR SCHATZKI Was the tumor in the lower end of the esophagus?

DR BENEDICT No, mid-thoracic

hours. The breech came down and was easily extracted under light ether anesthesia. There were no external tears, and very little bleeding. The patient was given 3 minims of posterior pituitary extract. Immediately following this medication, the patient strained violently, the fundus, inside out and with the placenta firmly attached, appeared at the vulva. Ether was resumed, and the placenta carefully peeled off. During this performance, there was surprisingly little bleeding. The fundus was grasped with one hand, squeezed carefully and with no difficulty replaced in the abdominal cavity. The cervix which had contracted about the inverted uterus was very easily dilated. The patient was given 5 minims of posterior pituitary extract, and the operator's hand was held in the uterine cavity until there was definite evidence of contraction. The cervix was then grasped with sponge forceps and brought down to the introitus for inspection. There was very little bleeding. The cervix was intact. The vagina was firmly packed and the fundus palpated. It was symmetrical and in normal position. During the manipulation the patient's pulse rose to 140 but remained of good quality. Her color was good and there was no sweating. She came out of the ether rapidly. She was watched carefully for one hour, during this time the fundus remained firm, there was very little bleeding and her pulse rate gradually dropped. The vaginal packing was removed twenty-four hours later.

Her convalescence was afebrile. The uterus involuted normally and the lochia was not foul at any time. The cervix was examined on the tenth postpartum day and appeared normal and well contracted.

*Comment.* This case of spontaneous inversion of the uterus may have resulted from the 3-minim dose of posterior pituitary extract. There was very little bleeding because the placenta had not separated at all when the inversion occurred. Furthermore, the fundus was replaced so quickly and so easily after the placenta had been removed and it remained so well contracted that the sinuses had no opportunity to remain open. The use of the vaginal pack after the uterus had been replaced was probably valueless. This condition, potentially so serious, was treated so quickly and so expertly that it is an example of how acute inversions should be handled. Practically all acute inversions, if treated immediately, can be replaced in this manner. It was extremely fortunate that so small an amount of blood was lost in this case, the hemorrhage is tremendous in most cases. Transfusion often plays a very important role in treatment.

## RHEUMATIC FEVER\*

Rheumatic fever is a common disease in Massachusetts. It is often called inflammatory rheumatism. It usually begins between the ages of five and fifteen years, although it may start in adult life. In some way, sore throats and colds are very closely connected with the beginning of rheumatic fever. This close association has been known for many years, but we do not yet know the exact cause of the disease. Chorea, commonly called St. Vitus's dance, occurs very frequently during rheumatic fever or in patients who have had rheumatic fever in the past.

At the beginning of the disease, the child or young adult often complains of a sore throat and is sick for two or three days, usually with slight fever. Recovery seems complete. Within a few days, or sometimes not for two or three weeks, there is the rather sudden onset of illness with high fever, a rapid pulse and sweating. Often pain occurs in the patient's joints—most frequently in the ankles, knees, hips, wrists, elbows and shoulders. The pain may be severe or slight, and at times the joints may be swollen and very tender. It is common for the pain to jump from one joint to another. There may be other symptoms such as nosebleeds, pain in the chest or stomach, vomiting and often rapid breathing. The diagnosis should be made only by a doctor.

Although the joints may be very painful at the beginning of the illness, this is not always so, and pain may be mild or absent. Rheumatic fever does not result in any permanent joint trouble. It is the heart disease caused by rheumatic fever which is the most serious part of the disease. In most cases, heart disease begins soon after the patient becomes sick. We now know that the heart disease is not a complication, but is usual in severe cases. All three layers of the heart are damaged. First, the lining, causing trouble with the proper working of the valves—often called leakage of the valves; second, the heart muscle, causing enlargement of the heart and, often, heart failure; third, the outside covering of the heart.

Once rheumatic fever has begun it usually lasts for weeks, more often months, and sometimes several years. It usually persists a shorter time in adults than it does in children. Adults also seem less likely to develop heart disease than are children. One of the worst features of rheumatic fever is that the patient is apt to have repeated attacks. These new attacks, or recurrences, are especially likely to take place during the first five or six years after the disease begins. For this reason, it is important for the patient to see his doctor often for some years after the initial attack. These repeated attacks of rheumatic fever usually follow sore throats and colds, but they may follow accidents, operations or various other diseases or they may happen without any known cause.

The symptoms during chronic rheumatic fever may be very mild, but are still important. I have told you what some of them are. Others are loss of weight, a non-itching rash, which does not last long, on the body, arms or legs, small, painless lumps or nodules over the joints, and jerky movements of the muscles indicating St. Vitus's dance. After these symptoms go away, laboratory tests may show that the disease is still going on. It is important to keep the patient quiet so long as there are symptoms or laboratory tests which show that the disease is still active.

A patient with rheumatic fever should be under the care of a doctor. When very sick, the patient needs the best medical care and good nursing. These patients are

\* Green Lights to Health broadcast given by Dr. T. Duckett Jones on Wednesday, April 26 and sponsored by the Public Education Committee of the Massachusetts Medical Society and the Massachusetts Department of Public Health.

If the family tradition is due to die out with the boy that wants to be an artist instead of a doctor, then let him take his paints and his palette and hie him to the Latin quarter, there to work out his own destiny

## CONTROL OF CANCER

THE tremendous complexity of the problems of cancer control and of research into the nature of cancer is such as to render any clear and comprehensive statement of our present knowledge extraordinarily difficult

Recognizing the value of stock-taking, even though somewhat superficial, a committee appointed by the Surgeon-General of the United States Public Health Service has prepared a report\* of the knowledge acquired in the last thirty years through experimental research, released by Dr Voegtlin, chief of the National Cancer Institute. The committee preparing this report consisted of Drs James P Murphy, John Northrop, Stanhope Bayne-Jones, Ross Harrison and Clarence C Little

The report brings out that a large number of diverse ways are known by which cancer may be produced. However, the exact mechanism by which these different substances actually alter cellular activity to cause cancer has not as yet been elucidated. This line of research, intimately concerned with cellular physiology, is being actively pursued in a number of different laboratories, but little information has been obtained as to why the cancer cell has unlimited and uncontrolled powers of growth within the body. Obviously, the complexity of this problem is such that a great deal of fundamental work will have to be done before any appreciable progress can be made.

The relation of heredity to cancer has been considerably clarified in the past, but still more work needs to be done, particularly in view of some of the recent experiments that emphasize the importance of certain extrachromosomal aspects of the hereditary transmission of relative resistance or susceptibility to the development of cancer

Of course, active search for new methods of treatment is an essential of any research program. Although we recognize that through education, leading to detection and treatment of early cases, we could achieve far better results with our present methods than are now being obtained, nonetheless it must be realized that even the best of our present methods leaves much to be desired. Much damage to normal tissues is still inevitable in eradication of the cancerous growth. How far one may go in finding a truly selective agent for the destruction of cancer cells is perhaps too nebulous for speculation, but nonetheless intriguing and important

### ACUTE INVERSION OF THE UTERUS

Mrs C K., a thirty-year-old primipara, entered the hospital February 19, 1939, at term and in labor.

The patient's family history was negative except that her maternal grandmother died of carcinoma of the breast.

The patient had had measles, mumps and scarlet fever as a child. She also gave a history of some kidney or bladder trouble. She had never had an operation. Catamenia began at the age of twelve, were regular with a twenty-eight-day cycle and lasted three to four days, without pain. Her last period was May 12, 1938, making her expected date of confinement February 19.

Physical examination at the beginning of her pregnancy revealed a well-developed and nourished woman. The heart was not enlarged, there were no murmurs. The lungs were clear and resonant. The blood pressure was 110 systolic, 80 diastolic. Pelvic measurements were normal. The abdomen was extremely firm on palpation. The course of her pregnancy was entirely uneventful. Routine examination at her last office visit revealed a breech presentation.

Labor was of short duration, lasting about five

A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

many patients with rheumatic fever. It seems to do no good, and at times may be harmful. I should advise against its use.

Q Is exposure to the sun of benefit to these patients?

A. If a patient is not very ill, exposure to the sun in small amounts is probably helpful. Heavy tanning is unnecessary. Actual sunburn should not be allowed. We have seen fresh attacks of rheumatic fever associated with severe sunburn.

Q In your discussion you mentioned loss of weight in connection with active rheumatic fever. Just what has weight to do with the disease?

A. Loss of weight and failure to gain weight are often found when the patient has active rheumatic fever, even mildly. As patients with rheumatic fever improve, they almost always gain weight. Weight is hence a rough guide to the patient's condition and should be watched.

Q What is meant by a person who says that he has "rheumatism"?

A. Rheumatism comes from the Greek word meaning "to flow." It has hence been used for all types of diseases in which pain occurs in different joints or even muscles. More recently, rheumatism has been used by doctors in those diseases in which the patient has real—often permanent—changes in the joints. This is more properly called arthritis, of which there are several types. Joint pain may occur in rheumatic fever, but may be mild or absent,—never permanent,—and heart disease is the important part of the condition. Hence, rheumatic fever should not be called rheumatism.

Q Colds and sore throats seem to be important in rheumatic fever. Have you any suggestion as to how these may be prevented?

A. There is no sure way of preventing colds and sore throats. Vaccines are not thought to be very helpful. The best way to prevent these infections is to stay away from people having them, as they are highly contagious. This, of course, is difficult. The rheumatic fever patient can help protect himself by staying away from crowds when colds are common, and even by keeping out of the way of brothers and sisters when they are sick. A common source of colds is the school. Intelligent teachers can help prevent their spread. It is wise for the rheumatic fever patient to have a room alone, or at least to sleep alone. He should avoid exposure, drafts, and so forth.

Q What is the present need in Massachusetts for the care of rheumatic fever patients?

A. The greatest need is for places where patients can receive long bed care during the stage of active rheumatic fever. Especially is this care needed for boys over twelve years of age and for young men. Very few beds exist for these groups. This is a crying need, and every effort should be made to meet it.

## DEATH

CROCKER—BENTON P. CROCKER, M.D., of Foxboro, died May 26. He was in his seventy-third year.

Born in Hyannis, he attended Amherst College and the University of Vermont Medical School and received his degree from the Bellevue Hospital Medical College in 1891. He became resident physician at the Winchendon Sanitarium and later was resident physician at the New York Lying-In Hospital. He went to Foxboro in 1894, where he had practiced since. He was town doctor for several years.

Dr. Crocker was a member of the Massachusetts Medical Society and the American Medical Association.

His widow, two daughters, two sons, a grandson and two sisters survive him.

## REPORTS OF MEETINGS

### HARVARD MEDICAL SOCIETY

At a regular meeting of the Harvard Medical Society held at the Peter Bent Brigham Hospital on Tuesday, March 14, Dr. Joseph Aub acted as chairman.

The first case, from the medical wards, was presented by Dr. A. C. England, Jr. A fifteen-year-old boy came in with a chief complaint of intense pain in the lumbar region of three weeks' duration. He had a past history of four attacks of chorea between the ages of eight and ten, each lasting one month. Two years previously he had developed osteomyelitis of the left hand, the fourth finger had to be amputated. Three weeks before entry he was injured while playing basketball and two days later developed intense pain in the left flank and then in the right flank. He was in bed at home two weeks, and as fever developed, he was brought into the hospital. On physical examination, one observed a feverish boy with a positive Kernig, stiff neck, costovertebral angle pain and tenderness, spasm of muscles, and a slight scoliosis at the tenth and eleventh thoracic vertebrae, concave to the left. His temperature was 102°F, the white blood-cell count was 13,000 with 80 per cent polymorphonuclears, lumbar puncture done twice showed clear fluid with no cells and a negative gold sol curve and Wassermann test, the blood Wassermann test was also negative. He was given bed rest and did well, with no discomfort and with lessening of the pain and stiffness of the neck. The scoliosis increased a bit but then made no further progress. By x-ray, a process in the base of the left lung cleared in five days. The spine plates were negative, but there was a shadow behind the heart which was associated with the scoliosis, with some erosion of the tenth and a narrowing of the joint space between the tenth and eleventh thoracic vertebrae. The patient was placed in a posterior shell and at present is afebrile.

Dr. Marshall Fulton in discussing the case brought up the possibility of the x-ray shadows being due to pus from the vertebra. Dr. Merrill C. Sosman re-read the x-ray films as showing a posterior gutter empyema. The first film showed a bronchopneumonic process, which probably went on to pleurisy and then empyema, with associated narrowing of the intervertebral space. However, this sequence might well have been in reverse order. Dr. Sosman thought the process was too acute to have been due to an acid-fast infection in the disk.

The second case was presented by Dr. C. F. Goeringer, and was from the surgical wards. The patient, a sixty-eight-year-old woman, was admitted March 5 for treatment of a three and a half months' progressive enlargement of a mass in the neck. She had had no thyrotoxic symptoms and had not lost any weight. Two and a half weeks before entry she began to have dyspnea and then orthopnea five days before entry her respirations became wheezing in character, and two days before became quite

best treated in hospitals. Hospital care becomes even more important if the patient has heart failure. As the patient improves, plans must be made for good bed care for a period of months. It is unfortunate that rheumatic fever occurs most commonly in families where the income is small and the home is crowded. Under such conditions it is hard to give the patient proper bed care for long periods of time. There exist a few hospitals and foster homes where this long time bed care may be given, but there are not enough beds at present to care for the large number of rheumatic fever patients. It is important during these long rest periods to allow the patient to learn something about the disease he has, to keep his mind occupied in instructive work or play, and to have his schooling continue. Massachusetts should be proud of an educational system which provides visiting teachers for these patients in their homes. All institutions giving long time care also provide schoolteachers.

There is much good advice which the doctor can give the patient or the family when the rheumatic fever is no longer active. Home conditions should be bettered, good nourishing food provided, rest periods suggested, and physical activity directed. The patient must be warned to avoid exposure to bad weather and to persons with colds and sore throats.

Rheumatic fever is important to us all. It causes 99 per cent of all heart disease in childhood and early adult life. For this reason, rheumatic fever is one of the important medical problems of the day. While rheumatic fever is a serious disease, by no means all patients with rheumatic fever develop severe heart disease or even have their future lives changed because of the disease. Many patients who have been closely watched over a period of years have little or no heart disease and are able to lead normal lives. In some cases, evidence of heart disease may disappear entirely, if the patient remains free of these later attacks of rheumatic fever. The severity of the attacks of rheumatic fever is the important point with regard to its effects. Some are so mild as to be discovered only by the physician. This is a further reason for frequent visits to the doctor.

In summary, the problem becomes one of proper care over a period of years. When very ill, the patient needs to be in a good hospital. Except in rare cases, long bed care must be given as the patient improves. With care to avoid sore throats and colds, further attacks may be prevented. The doctor should be seen often to determine whether or not the patient has active rheumatic fever, and to give helpful advice. If this can be done, in a majority of the cases the patient will be able to be physically active as he grows older.

\* \* \*

Q Is rheumatic fever inherited?

A Much study is at present being given to this question. We know that rheumatic fever often occurs in more than one member of a family, in fact, at least as often as does tuberculosis. Certain physicians believe that the disease tends to run in families. As yet, we cannot state for sure that it may not be mildly contagious. This may be more important than heredity.

Q Do you believe then that it is contagious?

A It has been well shown that rheumatic fever spreads through families as the result of sore throats and colds. Exactly how these infections play a part in rheumatic fever is unknown, but it is possible that during colds and sore throats the agent causing rheumatic fever may be spread from one person to another. However, this remains to be proved.

Q Do you think the cause of rheumatic fever will ever be found?

A Yes, but it may take many years. Several groups of research workers are carefully studying the disease. It is a very difficult problem, but one that physicians should be able to solve in time.

Q If a patient has had rheumatic fever with but little or no heart disease, what are the chances of his remaining well?

A The chances are excellent. The first two or three attacks of rheumatic fever usually cause the greatest amount of heart disease. If the patient has but little heart disease six or eight years after the first attack, the chances are greatly in favor of his remaining well.

Q Is diet a very important part in the treatment or prevention of rheumatic fever?

A In a general way, yes. There is no single food which is all important. It is wise to have an abundance of fresh vegetables, milk and fruit juices. Fruit juices supply vitamin C, which all patients with chronic infection need in large amounts. It is also wise to give the patient vitamin D during the winter months. This can be done with the use of cod liver oil or other preparations advised by the doctor.

Q You mentioned nosebleeds. Do they mean that a person has rheumatic fever?

A Most nosebleeds in children are caused by injury, such as blows or picking the nose. Nosebleeds occur frequently without injury during rheumatic fever, but the patient usually has other symptoms, and only a doctor should decide that they mean active rheumatic fever.

Q Why do you suppose rheumatic fever is commoner in families with small incomes?

A That is not answerable at present. It is probable that with poor living conditions and overcrowding, the patient comes in touch with more infectious agents and larger doses of them. In addition, poorer food may help lower the resistance of the patient.

Q You have not mentioned the tonsils. I was always told they could cause rheumatism, and I wonder if this is true.

A Formerly many doctors believed this to be true. Many patients, however, get rheumatic fever long after their tonsils have been removed. Also, we have noticed that taking out the tonsils seems to have little effect on the course of rheumatic fever. We still believe the tonsils should be removed if the patient has very many sore throats, or tonsillitis. Such an operation, however, will not cure the disease.

Q If a person in early adult life has rheumatic heart disease, what advice should be given him about exercise?

A If the heart disease is slight, and he has not had rheumatic fever for some time, the doctor will probably allow moderate exercise. If rheumatic fever is present, even mildly, he needs bed care. If rheumatic fever has been recent, an inactive life will be advised. If the rheumatic heart disease is moderate to severe, the doctor will advise moderation in exercise. In some patients it is necessary to avoid sudden strains, such as occur in violent games. In others, the patient must be taught to lead a quiet life and even trained to do some kind of work which can be performed without effort.

Q I wonder if the new drug, Prontylin, is helpful in rheumatic fever.

A No. Once a rheumatic patient has a sore throat it will not prevent a fresh attack of rheumatic fever. This drug is also known as sulfanilamide. It has been given to

many patients with rheumatic fever. It seems to do no good, and at times may be harmful. I should advise against its use.

Q Is exposure to the sun of benefit to these patients?

A. If a patient is not very ill, exposure to the sun in small amounts is probably helpful. Heavy tanning is unnecessary. Actual sunburn should not be allowed. We have seen fresh attacks of rheumatic fever associated with severe sunburn.

Q In your discussion you mentioned loss of weight in connection with active rheumatic fever. Just what has weight to do with the disease?

A. Loss of weight and failure to gain weight are often found when the patient has active rheumatic fever, even mildly. As patients with rheumatic fever improve, they almost always gain weight. Weight is hence a rough guide to the patient's condition and should be watched.

Q What is meant by a person who says that he has "rheumatism"?

A. Rheumatism comes from the Greek word meaning to flow. It has hence been used for all types of diseases in which pain occurs in different joints or even muscles. More recently, rheumatism has been used by doctors in those diseases in which the patient has real—often permanent—changes in the joints. This is more properly called arthritis, of which there are several types. Joint pain may occur in rheumatic fever, but may be mild or absent,—never permanent,—and heart disease is the important part of the condition. Hence, rheumatic fever should not be called rheumatism.

Q Colds and sore throats seem to be important in rheumatic fever. Have you any suggestion as to how these may be prevented?

A. There is no sure way of preventing colds and sore throats. Vaccines are not thought to be very helpful. The best way to prevent these infections is to stay away from people having them, as they are highly contagious. This, of course, is difficult. The rheumatic fever patient can help protect himself by staying away from crowds when colds are common, and even by keeping out of the way of brothers and sisters when they are sick. A common source of colds is the school. Intelligent teachers can help prevent their spread. It is wise for the rheumatic fever patient to have a room alone, or at least to sleep alone. He should avoid exposure, drafts, and so forth.

## REPORTS OF MEETINGS

### HARVARD MEDICAL SOCIETY

At a regular meeting of the Harvard Medical Society held at the Peter Bent Brigham Hospital on Tuesday, March 14, Dr. Joseph Aub acted as chairman.

The first case, from the medical wards, was presented by Dr. A. C. England, Jr. A fifteen-year-old boy came in with a chief complaint of intense pain in the lumbar region of three weeks duration. He had a past history of four attacks of chorea between the ages of eight and ten, each lasting one month. Two years previously he had developed osteomyelitis of the left hand, the fourth finger had to be amputated. Three weeks before entry he was injured while playing basketball and two days later developed intense pain in the left flank and then in the right flank. He was in bed at home two weeks, and as fever developed, he was brought into the hospital. On physical examination, one observed a feverish boy with a positive Kernig, stiff neck, costovertebral angle pain and tenderness, spasm of muscles, and a slight scoliosis at the tenth and eleventh thoracic vertebrae, concave to the left. His temperature was 102°F, the white blood-cell count was 13,000 with 80 per cent polymorphonuclears, lumbar puncture done twice showed clear fluid with no cells and a negative gold sol curve and Wassermann test, the blood Wassermann test was also negative. He was given bed rest and did well, with no discomfort and with lessening of the pain and stiffness of the neck. The scoliosis increased a bit but then made no further progress. By x-ray, a process in the base of the left lung cleared in five days. The spine plates were negative, but there was a shadow behind the heart which was associated with the scoliosis, with some erosion of the tenth and a narrowing of the joint space between the tenth and eleventh thoracic vertebrae. The patient was placed in a posterior shell and at present is afebrile.

Dr. Marshall Fulton in discussing the case brought up the possibility of the x-ray shadow's being due to pus from the vertebra. Dr. Merrill C. Sosman re-read the x-ray films as showing a posterior gutter empyema. The first film showed a bronchopneumonic process, which probably went on to pleurisy and then empyema, with associated narrowing of the intervertebral space. However, this sequence might well have been in reverse order. Dr. Sosman thought the process was too acute to have been due to an acid fast infection in the disk.

The second case was presented by Dr. C. F. Goeringer, and was from the surgical wards. The patient, a sixty-eight-year-old woman, was admitted March 5 for treatment of a three and a half months progressive enlargement of a mass in the neck. She had had no thyrotoxic symptoms and had not lost any weight. Two and a half weeks before entry she began to have dyspnea and then orthopnea five days before entry her respirations became wheezing in character, and two days before became quite

labored. Physical examination revealed an orthopneic wheezing woman with a temperature of 102°F and equal blood pressures in both arms. In the right side of the neck was a baseball sized mass, firm, non fluctuating, non-tender and slightly movable. X-ray films demonstrated the trachea deviated to the left. She was transferred to the surgical service, and two days later a decompression operation was performed. Biopsy suggested a tumor compatible with a lymphoblastoma. The patient's course improved following two x-ray treatments. At present she can lie flat in bed without distress. She is to have further x-ray therapy.

Dr Joseph C. Aub remarked that neoplasm of the thyroid gland was almost never hyperactive in function. Dr Elliott C. Cutler stated that the patient had had serious obstructive signs and that immediate x-ray therapy would have surely caused edema and death. For that reason a large specimen was taken at biopsy. Dr Cutler said that at the time of operation he did not believe it was a lymphoblastoma, but also that it was not typical of an epithelial tumor of the thyroid. Dr Guy D. Ayer reported that preliminary pathological study indicated an undifferentiated small-cell malignant tumor, the cells being related to blood vessels and occasionally containing vacuoles. Therefore, he predicted a thyroid tumor of rare type.

The main program of the evening was a symposium on "How Does One Study Cancer?" presented by six of the investigators from the Collis P. Huntington Memorial Hospital.

Dr Aub introduced the topic by briefly reviewing the history of cancer research. He said that, in general, cancer is still an unknown entity. Neither is it known what change in the cells predisposes to cancer, nor is therapy as yet satisfactory. Since the turn of the century, however, a great deal of information has been gathered, as a result of the discovery of x-rays in 1895 and of radium in 1898. The Huntington Hospital was founded in 1899. In 1903 the first successful transplantation of a tumor from animal to animal was achieved. In 1907, Dr Tyzzer established the fact of inheritance of tumors, a most fundamental discovery. In 1911 two Japanese investigators first produced tumors in animals by rubbing tar into the skin. Previous to that it had long been known that chimney sweeps often developed cancer. In 1910 Carrel grew tumors in vitro. Rous and Murphy produced filterable virus tumors in chickens. In 1923 Warburg made his great discoveries, and in 1931 tumors were produced by a crystalline substance derived from tar. This all means that within the last forty years all the techniques or tools necessary for producing and studying tumors have been made available to investigators.

The first paper was presented by Dr I. T. Nathanson on "The Effect of Testosterone on Development and Growth of Spontaneous Mammary Cancer in Female Mice." Spontaneous mammary cancer in female mice has been developed and its incidence standardized by inbreeding of pure strains. Loeb, of St. Louis, castrated such female mice before puberty and thus reduced this incidence. If spayed after puberty the incidence was also decreased, but was not so marked. Lacassagne injected the female sex hormone into mice of both sexes and increased the incidence of mammary cancer. Others have confirmed and extended this work. Recently, Lacassagne injected testosterone into high-cancer female mice, in small doses, and obtained no effect. The author, using larger doses, undertook the same problem. Some 40 mice of approximately the same age and of the same descent were divided into two groups of 20 each. These mice ordinarily develop tumors in six to eleven months after

birth if mated once. One group was given testosterone propionate in 0.5 mg. doses in 0.05 cc. of sesame oil three times a week just after the age of four months and after parturition. At the eighth month of age, 6 of the treated mice had developed mammary cancer whereas 11 of the controls had cancer. After the eighth month no more of the testosterone treated mice developed tumors, whereas 100 per cent of the control mice had developed tumors by the twelfth month. At this time mortality due to the testosterone injections per se came into consideration. Ten animals of the treated group were still living, without tumor, at eighteen months of age. All control animals died with tumor by the fourteenth month. Of the treated mice none had more than one tumor, whereas in the control group 12 developed two or more tumors.

An experiment to study the effect of testosterone on the growth of existing tumors was carried out on 48 animals, half of which were used as controls. The mean diameter based on measurements of the tumors in three planes was used for comparison. Doses up to 5 mg. per day had no effect on the rate of growth of the tumors.

Histological studies on the experimental material revealed that the effect of testosterone is on the glandular acini and ducts producing a change toward the male type of mammary gland, both in virgin and in pregnant mice. Dr Nathanson concluded by stating that the experimental evidence presented indicated that estrogens are not carcinogenic per se as regards mammary cancer in mice.

The second paper on Tissue Inhibitors was given by Dr A. M. Brues. Individuals on becoming adults have their growth completely inhibited except in emergencies such as the repair of wounds. Cancer does not seem to be controlled in this way. Tissue cultures when liberated from the body grow freely, but the more adult the tissue the longer it takes to shake off the shackles of inhibition. Since the tissues become free of the inhibitory factors, they make good subjects on which to test the inhibiting powers of various substances. Thus, simple saline liver extract is a good tissue growth inhibitor. Dr Subbarow has been able to isolate a substance which is non-toxic but a good inhibitor. This compound is ethanolamine. It has been shown that the extracts do not interfere with tissue metabolism, and embryonic hearts keep on beating in their presence. Dr Brues found that inhibition of growth by amines was much more effective at pH 8 than at pH 7, and that malignant growths flourished in a zone far out on the alkaline side and in high concentrations of the inhibitor, where normal tissue would not survive. Is this because the interior of a tumor cell is more acid than normal? This is likely, but difficult to prove. Various other inhibitors were studied, but the amines described were the only substances capable of so differentiating normal and malignant cells.

Dr William T. Salter presented the third paper on Comparison of Benign and Malignant Tumors. Implanted tumors in animals are now surprisingly uniform and reliable in their transmission. There is also a standard method of producing malignant disease experimentally by this means, and the histological character of tumors so produced is well known. With this for ground work, Dr Salter experimented on tumor immunity. A tumor of well known character and properties was implanted on the tail of a pedigreed mouse from a highly inbred strain. After a time the tail was amputated, and a second implantation of the same stock sarcoma was tried on the mouse's body. Whereas in control animals takes occurred in practically 100 per cent of cases, in

the "immunized" mice the incidence of body-takes was materially reduced. Besides, in some such mice the implanted malignant tumors became slow growing and less malignant, and in others the growth was benign. The percentage of mitotic figures after administering colchicine was used as a check on the mitotic activity. Theelin, administered subcutaneously, was found to increase this "tumor immunity." Dr. Salter and his collaborators studied the resultant benign and malignant tumors by comparing their respective metabolisms of oxygen, carbohydrate and nitrogen, and could determine no characteristic difference between the artificially "benign" and the malignant sarcomas. Therefore, he concluded that benignancy is a property of the host as well as of the tumor itself.

Dr. Shields Warren talked on "The Contribution of Pathology to Guidance in Radiation Therapy." Radio-resistance and sensitivity have so far been based largely on empirical grounds. As a general rule, the more embryonic the cell type the more radio-sensitive it is, but exceptions are almost as frequent as the cases that follow the rule. It is for that reason that different tumor types have been sorted and classified on a basis of previous experience with respect to radio-sensitivity. However, one has found that in almost all cells the early prophase is the mitotic stage at which sensitivity is greatest. Certain changes take place in irradiated cells: mitosis is arrested or disturbed, later, vacuolization occurs—abnormal cells appear or calcification develops, the Golgi apparatus shows various stages of swelling, with subsequent disintegration or a return to normal, the same changes occur with respect to the mitochondria. A sublethal dose is followed by a tendency to recovery in eighteen to twenty hours. For this reason, radiation once a day is sound therapy. Another fact that has been discovered is that in plant cells the longer the chromosomes the better is the response to radiation, with some exceptions. This may be a good clue to a future classification of tumors for prognostic and therapeutic purposes.

The fifth paper was presented by Dr. Richard Dresser, "Results of Radiation by the Million Volt Machine on Bladder Tumors." The electrostatic belt-conveyor type of supervoltage x-ray machine has been brought to a high degree of mechanical perfection. The wave lengths of the beam at a potential of one million volts are shorter and more penetrating than any x-rays thus far generated for therapeutic purposes. Briefly, the advantages of this type of radiation are fourfold: 20 per cent more radiation can be delivered to the center of the human pelvis than is possible with 200-kilovolt rays, the skin tolerates nearly twice as much million volt radiation, when smaller portals of entry are employed, there is less general reaction on the part of the patient, the amount of radiation delivered to a deep-seated tumor is largely independent of the size of the portal entry. In a series of 24 cases of bladder tumors treated with 200-kilovolt rays, which was recently reviewed in collaboration with Dr. Roger Graves, it was concluded that external radiation by this method was of value only as a palliative measure. Thus far, 57 cases of carcinoma of the bladder have been irradiated by the million volt machine. In round figures, a third of these cases have shown complete regression, a third partial regression and a third no response to treatment. It is believed that the dosage thus far administered is not curative, but a greater palliation has been secured than with other external methods of radiation. In the brief experience of two years, the technic of million volt radiation has of course, been improved.

The sixth and last presentation was by Dr. Grantley W. Taylor, "Surgical Treatment of Cancer of the Lip." Dr.

Taylor stated that the problem in treating cancer of the lip was to decide when to operate on the neck nodes. He did not give any opinion on this score, but merely presented statistics from which one could draw conclusions. The cases reviewed came from the Huntington, Pondville and Massachusetts General hospitals. The first factor considered was the size of the tumor, since it roughly indicated the duration of the disease and the amount of metastasis. Of 93 patients with carcinoma less than 1 cm. in size, 7.5 per cent had positive lymph nodes, and of these last, 57 per cent were cured by radical surgery. Of 328 patients with a tumor 1 to 2 cm. in size, 13 per cent had positive nodes, of which 55 per cent were cured. Of 136 patients with a tumor 2 to 3 cm. in size, 37 per cent had positive nodes, of which 51 per cent were cured. Finally, of 59 patients with a cancer larger than 3 cm., 24 per cent had positive nodes, of which 43 per cent were cured, but this was actually a group favorably selected for surgery. The second factor was the duration of the lesion, but as with all historical data, it is apt to be inaccurate. The third factor was the grade of the carcinoma. Grade 3 tumors had the highest incidence of positive nodes. The fourth factor was the presence and size of the cervical lymph nodes in relation to their actual involvement. Of those with nodes less than 1 cm. in size, 10 per cent were positive on biopsy, of nodes over 2 cm. in size, 91 per cent were positive.

#### SUFFOLK DISTRICT MEDICAL SOCIETY AND NEW ENGLAND PEDIATRIC SOCIETY

On Wednesday, March 29, 1939, at the Boston Medical Library, there was a combined meeting of the Suffolk District Medical Society and the New England Pediatric Society, at which Dr. Albert D. Kaiser of Rochester, New York, spoke on "Significant Facts in the Tonsil Problem in Children." Dr. R. Cannon Eley presided.

In emphasizing the importance of the problem, Dr. Kaiser reminded the audience that the question of the removal of tonsils and adenoids comes up for decision in almost every child before the school age has been passed. For, although nutritional problems, with special emphasis on the vitamins and minerals, have been indicted with increasing frequency in the retardation of growth, the tonsil still receives considerable notoriety. More recently, the vogue for chemotherapy in upper respiratory infections has been holding the spotlight. In the face of this confusion, therefore, it behooves the doctor to know how to evaluate the operation for removal of the tonsils and adenoids in children. Dr. Kaiser bases his conclusions on 4400 cases, equally divided into operated and unoperated groups, and presents his data as answers to commonly asked questions.

Do tonsils have any useful function in a young child? They play a role similar to other lymphoid tissue in regard to drainage of infected foci, as shown by a group of English workers who injected dyes and bacteria into the paranasal sinuses and demonstrated their excretion through the tonsils. This protective mechanism is especially potent under five years of age, when the lymphoid tissue of the pharynx shows its greatest development and when removal of the tonsils increases the incidence of infection, according to Dr. Kaiser's data. Some recent work by the speaker is suggestive that the vitamin C levels of tonsillar tissue and the blood have similar values, and that the numbers of bacteria that can be cultured from the center of the tissue are inversely proportional to the vitamin C content. It is concluded, therefore, that the tonsil does play a protective role of some nature, at least in children under five years of age.

Is the presence of tonsils a handicap to normal development? Unless there is some specific indication for tonsillectomy, no advantage accrues to the operation. Twelve hundred cases which were recommended for removal but failed to undergo surgery showed comparable development to 1200 operated cases, and in general fared as well except for a slight increase in the number of sore throats and rheumatic infections. Furthermore, those patients who had the 'benefits' of tonsillectomy under five years of age showed no definite improvement except in obstructive symptoms, either of deglutition or breathing. Examination ten years later of the two groups showed barely perceptible differences in the size of the tonsils, presumably due to atrophy in the unoperated group. Dr Kaiser concludes from this study, therefore, that no doctor need fear that failure to remove the tonsils is a grave error of omission.

Is the incidence of infection decreased by tonsillectomy over a control group when the preoperative indications are the same? Data based on 4400 cases equally divided indicate that the common complaints are recurrent tonsillitis, head colds, otitis media, cervical adenitis, lower respiratory infections, measles, diphtheria, scarlet fever and rheumatic fever. The only statistically significant improvement in the operated group after ten years is the lowered incidence of tonsillitis, cervical adenitis and rheumatic fever, while the reduction in the number of head colds is suggestive. Laryngitis, bronchitis and pneumonia show a higher incidence in the operated group here as in other studies, but this is probably a reflection on the susceptibility of those chosen for surgical intervention rather than on the procedure itself. One may conclude, however, that tonsillectomy does not protect against the latter infections. Although the operated group shows a statistically insignificant decrease with regard to scarlet fever, there is little doubt but that the course, when the disease is contracted, is smoother and the prognosis more favorable than it is in the unoperated group.

Rheumatic infection constitutes the most debated if not debatable subject. In the first place, it is generally accepted that tonsillectomy is not indicated in a patient with chorea, who becomes worse, if anything, after operation. In regard to the joint and cardiac manifestations, however, there is more hope. For, although the incidence of initial attacks is reduced only 20 per cent or less by removal of the tonsils, the greatest value lies in the reduction in mortality. Thus, those who retained their tonsils had a 13 per cent mortality, while those whose tonsils were removed at the first attack had a 7 per cent death rate and after the first attack one of only 4 per cent. This occurred in the face of no reduction in recurrences. Dr Kaiser interprets these data to mean that some benefit is to be gained by removing tonsils which are subject to repeated infections.

To Dr Kaiser's way of thinking, contraindications to tonsillectomy include such conditions as acute infections, particularly respiratory, pulmonary diseases and blood dyscrasias. He emphasized the importance of refraining from operation during an acute rheumatic episode. There is evidence accumulating which indicates that the poliomyelitis season should be avoided, for the high incidence of the bulbar form of this disease in patients who have recently undergone tonsillectomy seems more than mere coincidence.

The speaker's indications for tonsillectomy rest on the compilation of these extensive data, and striking benefits may result when operation is based on proper preoperative indications. In obstructive symptoms one may expect 75 per cent improvement, in sore throats, cervical adenitis and cyclic vomiting, 50 per cent, in recurrent

colds, otitis media and rheumatic infection, 25 per cent, and in asthma, pneumonia, bronchitis and chorea, none. The appearance of the tonsils is not a reliable criterion for operation, for the removal of small, clean looking ones is often as beneficial as that of those which are large, boggy and purulent—provided the indications are otherwise comparable. Probably the most important single factor in determining the advisability of tonsillectomy is an accurate history. Although it is no disgrace to refuse to perform the operation, it should be elected in proper instances.

In opening the discussion, Dr Francis L. Weille warned that Dr Kaiser's data might be widely employed as a basis for the wholesale retention rather than removal of tonsils. Using Dr Kaiser's own statistics on otitis media, Dr Weille stated that, in his opinion, the benefits claimed had been greatly minimized, for although the incidence of this condition normally decreases in the age group between five and fifteen years, the number of cures in the operated group is approximately twice that of the controls, which is most significant.

Dr Kaiser replied that he merely attempted to interpolate the fact that those in the unoperated group were probably progressing satisfactorily whereas the others were more susceptible. In other words, it is practically impossible to obtain biologically equal groups.

Dr Warren R. Sisson asked the following questions: Granted that it is desirable to remove diseased tonsils and retain normal ones, how shall one determine the latter? How can the number of cases unnecessarily operated on be reduced?

Dr Kaiser replied that the definitely pathologic tonsils with expressible pus and cervical adenopathy throughout the winter season present no diagnostic problem. There is no good criterion, however, in border line cases, and the history is still an indispensable asset. The school doctor, on one cursory examination, can express no reliable opinion, although he often does make an indelible impression on a child's mother by such a proclamation.

The problem of reducing the number of superfluous operations lies at least partly in the social system, for the incidence in Buffalo varies from 30 per cent in the poorest public school to 98 per cent in one of the better private schools. This direct relation between tonsillectomy and social status obtains throughout the entire scale, not only there but in other large cities. Neither extreme is probably the correct proportion, unnecessary operations constituting approximately 25 per cent.

Dr Lyman G. Richards asked whether there was any reason why the adenoids should not be spared when there are no specific indications for their removal except as a part of the operative procedure. He added that it has been asserted that they may exert a sparing action, whereas their removal merely stimulates reaccumulation of lymphoid tissue in the nasopharynx.

Dr Kaiser replied that there are no statistics on this important problem, and the conjecture is that it may be wiser not to denude the entire nasopharynx for Nature certainly causes tremendous lymphoid hypertrophy during subsequent infections of that region. The opposite suggestion, of removing only the adenoids, seems logical for recurrent head colds. Comparison of the results in patients with complete and incomplete removal of the pharyngeal lymphoid tissue shows essentially no difference after a ten year period.

Dr Harold G. Tobey said that the importance of the problem in relation to deafness demands more attention. Of the more than 3,000,000 deaf in the country, only 5 per cent of the cases are due to the main congenital causes—otosclerosis and nerve deafness. The adhesive type which

occurs at fifteen to twenty years of age, is undoubtedly associated with repeated closure of the eustachian tube, and otitis media and mastoiditis are not necessarily factors. In view of this important economic loss, the number of operations is no disgrace, and certainly complete removal of lymphoid tissue, especially in the fossa of Rosenmüller, is indicated.

Dr Kaiser said that tonsils and adenoids certainly should be removed in the face of recurrent middle-ear infections or incipient deafness, but that there is no suggestion that such procedure is beneficial prophylactically. Mastoiditis, like sinusitis, has an increased incidence in the operated group. But this does not vitiate the fact that mastoiditis is not necessary for adhesive deafness.

Dr Conrad Wesselhoef added that tonsillectomy more favorably affects the course and sequelae of scarlet fever than statistics suggest. In the first place, about 25 per cent fewer contract the disease, although they may have a sore throat. But more important is the interpretation of the data which seem to indicate that the procedure is of questionable value in preventing the complications of otitis media and mastoiditis. These very conditions are the indications for tonsillectomy, and these same children without operation would show to even worse advantage compared with a so-called control group in which operation was not performed.

To the question as to what were his indications for operation, Dr Kaiser replied that, under five years of age, obstruction and deafness demand intervention, while over five years the indications are recurrent tonsillitis and cervical adenitis, rheumatic fever, cyclic vomiting, and malnutrition when all else has been ruled out.

Dr Charles F. Walcott said that the individual patient cannot be judged by age or any set criteria, and that it is often wise to ask what one would do with one's own child. Advice should always be sought from the family physician, who is well acquainted with the patient and with the reaction during past attacks and during quiescent stages. One examination during one attack is not sufficient for a consulting specialist to make an intelligent decision as to the advisability of a tonsillectomy.

#### ALPHA OMEGA ALPHA

At the Harvard Medical School on April 28, President Donald D. Matson, of the Harvard chapter of Alpha Omega Alpha, presented Dr Eugene M. Landis, assistant professor of medicine at the University of Pennsylvania School of Medicine, who spoke on "The Effects of Kidney Extracts on Blood Pressure."

In introducing his intriguing subject, Dr Landis reminded his audience that results so far obtained in the field of experimental hypertension, while of the highest importance, must still be amplified and extended before clinical application is possible. However, any additions to or improvements in the present knowledge of the etiology and pathogenesis of this distressing and fatal condition will of necessity show the direction for further investigation and treatment. After the conclusion of his humble prelude, this contributor to the field of vascular physiology proceeded to delight his audience with a well organized, well presented and fundamentally sound report on the work being carried on in Philadelphia concerning the physiologic activity of extracts prepared from kidney tissue.

In a short review of the outstanding historical developments in cardiorenal vascular physiology, Dr Landis re-emphasized the well known controversy between the schools which postulate the kidney or the general vascular system as the primary instigator of hypertension. With the

introduction by von Basch of the sphygmomanometer into clinical medicine, it became apparent that abnormally high blood pressures in the absence of clinically significant morphologic changes of the kidneys and arteries were not uncommon. This disease or syndrome has been successively called the prealbuminuric stage of chronic Bright's disease, latent arteriosclerosis, hyperpiesia, presclerosis, hypertensive cardiovascular disease and benign or malignant nephrosclerosis, but the ever-increasing and changing nomenclature has not clarified the underlying problem to any great degree, although it has indicated changing concepts. In Bright's original description of chronic nephritis in 1827, he considered the cardiac hypertrophy to be secondary to the underlying renal disease. This concept, carrying as it did such great prestige, prevailed universally until the introduction of the sphygmomanometer in 1893. In the succeeding years, it occurred to such men as Allbutt and Huchard that the hypertension might lead to general arteriosclerosis and thus affect the kidney secondarily. With newer clinical or pathological observation, theories of pathogenesis have alternated between these views.

In an endeavor to elucidate the nature of essential hypertension it was only natural that a pressor substance should be sought. As early as 1898, it was demonstrated that an extract of rabbit kidney produces an inconstant and temporary increase of blood pressure. Due to the inconsistency of this and subsequent results, interest began to lag, only to be revived by Goldblatt's epochal experiments in 1932, which have practically revolutionized this field. Partial clamping of both renal arteries resulted in maximal and prolonged rise of both systolic and diastolic blood pressures, and further experiments suggested that hypertension is produced by a humoral mechanism. It has been supposed that a substance formed in the ischemic kidney may be responsible, but this substance has never been isolated from, or demonstrated in, the circulating blood.

It became apparent that an improved technic of preparing kidney extracts might confirm the former experiments in this direction. Consequently, Dr Landis and his co-workers embarked on the problem presented herein.

In order properly to interpret the results obtained with any vasopressor substance, it is necessary to understand the fundamental conditions of the circulation in the human hypertensive patient. Prinzmetal and Wilson, as well as Pickering, demonstrated by the plethysmograph that the rate of peripheral blood flow in the forearm remains normal despite greatly increased blood pressure. Furthermore, the response to various thermal and nervous stimuli in hypertension is perfectly normal. There must, therefore, be a generalized increase of peripheral vascular tone and resistance, but with the maintenance of the usual flexibility of tone. In order to determine whether these conditions were met in the experiments, Dr Landis tested the rabbit's ear for surface temperature and pulse amplitude as a measure of peripheral blood flow and vascular tone.

It was found that heated kidney extract and one of its constituent compounds, tyramine, would each raise the blood pressure of the rabbit by approximately 25 to 35 mm of mercury. However, the former showed no effect on the skin temperature or amplitude of pulsations, whereas tyramine induced vasoconstriction and decreased blood flow in the ear. Similar injections of epinephrine, Pitressin, Pituitrin-S, guanidine, methyl guanidine, dimethyl guanidine, ergotoxin and ergotamine produced a comparable rise in the blood pressure but also a decrease of the skin temperature and pulse amplitude. Such substances, therefore, temporarily elevate blood pressure by

a mechanism fundamentally different from that found in human hypertension

It became evident very early in this work by Dr Landis that the technic of preparing the kidney extracts played an important role in the type of reaction noted. With crude, unheated extract, for instance, the blood pressure might rise, fall or show no change. There was always, however, a conspicuous decrease in the peripheral flow. On the other hand, rabbit kidney extracts heated to 55°C for twenty minutes and then filtered, uniformly elevated systolic blood pressure 30 or 45 mm, with a slow onset and a duration of thirty to forty five minutes. Furthermore, there was never decreased peripheral circulation and, in rare instances, even an increased skin temperature was noted. Extracts heated to 60 or 65°C had no significant effect on blood pressure or peripheral blood flow. Since the amount of protein precipitated increases with the degree of heating, there seems to be suggestive evidence that this is an important fraction in producing hypertension. Dr Landis emphasized, however, that although the mechanism of vascular tone prevails as in human hyperpiesia, the blood pressure is maintained only temporarily at its elevated level in these experimental rabbits.

Before determining the effect of this extract on Goldblatt rabbits, it was necessary to ascertain whether vascular flexibility comparable to the normal was preserved in these animals. Measurement of the skin temperature of the ear demonstrated that the hypertensive animal was entirely capable of responding to temperature and nervous stimuli by changes of vascular tone. Having established this fundamental similarity, rabbit kidney extract was injected into Goldblatt rabbits with an immediate and temporarily sustained rise of blood pressure from 120 to 180 mm and with no change in skin temperature or pulse amplitude. The response to this extract, therefore, is obtained regardless of the original base line. And the sensitivity of the hypertensive rabbit is neither more nor less than that of the normal animal, as shown by the same average increase of blood pressure in each instance.

In all these experiments, Dr Landis has used homologous extracts and donors, due to the general unreliability of results from heterologous injections. To determine the distribution of the hypothetical pressor substance in various species, however, some of the latter type of experiments have been carried out. It is necessary to limit heterologous injections to a single attempt because of subsequent acquired sensitivity. By using kidney extracts from man, rabbit, rat, dog and guinea pig and employing the dog, rabbit, rat and guinea pig as recipients, it was determined that this pressor substance is generally distributed but in various amounts. Thus, the rabbit kidney extract gave an average rise of blood pressure of 43 mm, compared with that from man, which caused an average rise of only 4 mm. On the other hand, the greatest reactivity was demonstrated by extracts from the guinea pig and rat, which were almost twice as responsive as those from the dog. These illuminating data may shed light on previously confusing experimental results.

Various investigators have suggested that some relation may exist between the globulin content of the kidney extracts and their hypertensive potency. Dr Landis's statistics, however, do not allow him to agree with this postulate, for extracts from all species of laboratory animals contain similar amounts of globulin but exhibit the varying activities enumerated above. Yet the pressor substance of kidney extracts accompanies the globulin fraction, as demonstrated by experiments involving heat precipitation, ultrafiltration and fractional salting out by ammonium sulfate.

For assay purposes, human kidney extracts are now be-

ing precipitated by half saturated ammonium sulfate, as well as by heat. The potency of the human extract, however, still falls far short of that from the rabbit kidney. Furthermore, clear-cut pressor effects have so far been obtained only with extracts from kidneys of young individuals with severe malignant nephrosclerosis. The number of human cases so tested, however, is still too small to permit definite conclusions.

Dr Landis emphasized the fact that experimental hypertension produced by heated kidney extracts is only partially similar to essential hypertension in the human being, for the elevated blood pressure is only temporarily maintained. The speaker also advised caution in drawing any broad conclusions from studies of pressor substances until their presence and effectiveness in the blood stream have been established beyond doubt.

In summary, Dr Landis again focussed attention on the fundamental dissimilarity between the vascular background of hypertension as produced by the vasoconstrictor drugs on the one hand and suitably heated kidney extract on the other, the latter simulating much more closely the conditions in human hyperpiesia. He said that he believed that these results may point the way for further investigation, but that the 'provocative similarity' between the effects of kidney extracts and the circulating mechanics of clinical hypertension offers, at present, no certain proof of the pathogenesis of hypertension in man.

## NOTICES

### REMOVALS

GEORGE L. TOBEY, JR., M.D., HAROLD G. TOBEY, M.D., CHARLES I. JOHNSON, M.D., LEROY A. SCHALL, M.D., and MERRILL WITTLES, M.D., announce the removal of their offices from 270 Commonwealth Avenue to 403 Commonwealth Avenue, Boston Telephone KENmore 9620

### ANNOUNCEMENT

JAMES HARRISON, M.D., announces the opening of an office at 120 Needham Street (Riverdale), Dedham

## SOCIETY MEETINGS AND CONFERENCES

### CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY, JULY 3

#### FRIDAY JULY 7

\*10 a. m. 12 30 p. m. Boston Dispensary tumor clinic

#### SATURDAY JULY 8

\*10 a. m. 12 m. Staff rounds of the Peter Bent Brigham Hospital Conducted by Dr. Marshall N. Fulton

\*Open to the medical profession

## BOOK REVIEWS

*Dysmenorrhoea* Albert A. Davis 254 pp London, New York and Toronto Oxford University Press, 1938 \$4.50

Davis classifies dysmenorrhea as primary and secondary, according to whether the pain starts with the onset of the menstrual life or some years later, but acknowledges that most of those having a definite pathologic cause fall in the latter group. The chief symptom is described as spasmodic and congestive, the latter applying usually to the secondary type. This book is concerned with the primary type of dysmenorrhea.

Under etiology he considers the incidence of the disease, age of onset, severity, and so forth, giving a good review of the present knowledge. He believes the cause of the pain to be muscular contractions of the uterus, going into detail regarding the normal rhythmic cycles of contractions, and that the contractions are excited by chemical stimulation of the nerve endings. The various theories, such as the obstructive, hormonal, expulsion of endometrial plaques, hypoplastic, allergic, hyperesthetic and neurogenic, are considered in detail. He believes that eventually most cases will be proved to lie in the hormonal and neurogenic fields.

Under hormones he describes the stimulating and inhibiting effects of estrogen and progesterone on uterine contractions and is of the opinion that an imbalance will be proved to be the etiologic factor. The pituitary enters the picture by the stimulating effect of prolactin on the ovary and that of pituitrin on the uterine muscle, but he says the degree of their influence has not been decided. He can find no evidence of participation by the thyroid, parathyroid, thymus and adrenal glands. Fifty-five pages are devoted to the neurogenic theory, with a description of the anatomy of the autonomic and somatic nerve supply to the uterus and a discussion of the functions of the different systems regarding which there is a great difference of opinion. He describes inflammatory changes in the ganglion cells of the sympathetic system, which he thinks are characteristic in primary dysmenorrhea and occur in three quarters of the cases. He concludes that "The pain may be due to exaggeration of either motor or sensory impulses by a nerve rendered hypersensitive through inflammation."

There are good chapters on membranous, secondary and intermenstrual dysmenorrhea.

Under treatment the various constitutional measures, exercises and drugs are first considered. The drugs are taken up in detail, and the various proprietary products studied. He believes that organotherapy is very disappointing, but should be tried, especially the anterior pituitary hormone and small doses of thyroid extract. Alcohol injection into the nerve plexuses on each side of the pelvis where the various uterine nerves come together is described in detail, and 60 per cent of good results reported, but not the number of cases treated. Dilatation of the cervix is a valuable adjunct to other methods, but the use of tents and stem pessaries is condemned. The technique of presacral neurectomy is well described, as well as its difficulties and dangers. He finds that 75 per cent are cured and the rest much relieved, and recommends that it be reserved for failures after simpler types of treatment.

There is a bibliography of 28 pages.

Thus is a sensible, well written book which would be more convincing if series of cases were tabulated for each of the chapters, however, it gives a complete picture of the subject.

*Principles of Hematology* Russell L. Haden. 348 pp Philadelphia Lea & Febiger, 1939 \$4.50

For a long time, there were no American texts on hematology. In the last few years, there has been a bumper crop, and almost every hematologist of note has contributed his opus—Castle and Minot, Downey, Os-good, Kracke, Sturgis and Isaacs, Murphy and, now, Haden. Some say, rather cynically, that textbook writing in any field is a sure sign of its approaching decadence. In the feverish decade of activity in hematology, dating from 1926, textbooks were scarce, although advances were many. Is the order now to be reversed? The monumental *Handbook of Hematology* edited by Downey, is undoubtedly the most erudite American work in this field, and serves only a limited audience. Haden's book, on the other hand, is aimed quite frankly at the much larger field which includes the general practitioner. The wealth of illustrations is perhaps the outstanding feature of the book. Although no colored lithographic plates are present, the photographs are mostly carefully selected and excellently executed, they actually illustrate. Unless one customarily thinks in visual terms, as the author apparently does, some of the numerous diagrams may on occasion be confusing. One may question the wisdom of illustrating even the smallest point by a mechanistic diagram.

Surrounding this mass of illustrations is a rather small amount of text. Probably in the interests of simplicity, the wording is often quite dogmatic, and controversial subjects are dismissed with a few words. The reader's interest, however practical it may be, is rarely stimulated to go a little more deeply into a given subject. (The entire bibliography consists of thirty-nine references.)

The several chapters on methods, on granulocytes and their reactions, and on the treatment of anemia and polycythemia are good. The chapter on the mechanism of anemia and polycythemia might be improved if some of the many diagrams were omitted. Far too much attention seems to be paid to the volume and saturation indices, rarely used by the general practitioner. The statement that small transfusions are valuable for a stimulating effect on the bone marrow is to be doubted. Bone marrow biopsy—whether by trephine or puncture—is neither described nor discussed. Despite their widespread use there is very little on transfusions or blood storage and nothing regarding methods of blood typing. The heterophil agglutination test for infectious mononucleosis is dismissed with a simple mention, and this important disease is considered in only one of the one hundred case reports given at the end of the book. There is no mention of vitamin K and its relation to prothrombin.

Despite its deficiencies, the book will probably prove to be popular with the general practitioner desiring an introduction to hematology. The illustrative cases are well selected and without question a valuable feature. The book undoubtedly represents a sincere attempt to educate the average physician, and for this it should be commended.

*Infections of the Hand: A guide to the surgical treatment of acute and chronic suppurative processes in the fingers, hand and forearm* Allen B. Kanavel. Seventh edition. 503 pp Philadelphia Lea & Febiger, 1939 \$6.00

It is a sad privilege to review this seventh edition of the late Dr. Kanavel's classic work. The publishers note should be read. The volume is more compact than the sixth edition. The type, the number of chapters and the chapter headings are the same. Changes in phraseology have been

made throughout. Some chapters have been condensed and others expanded. A half dozen illustrations have been omitted, another half dozen altered, and fully twenty new ones introduced. Nevertheless the new edition is short er by forty pages.

An oblique, rather than a vertical, incision through the radial border of the palm is described for drainage of the thenar space. A more or less transverse incision, often directly along the distal flexion crease, is being used for draining the middle palmar space, rather than the earlier vertical incision. Roentgen irradiation in therapeutic doses in the early stages of infection has been found of value since the publication of the sixth edition. A considerable addition has been made concerning the treatment of chronic undermining burrowing ulcers with zinc peroxide, after the method of Meleney. Only cautious references are made to the use of sulfanilamide as an adjunct to surgery. This is consistent with Dr Kanavel's purpose that all the editions of his monograph be safe and sound guides for the practitioner. His life was cut short before the scientific control of the administration of the drug had been developed.

The exposition of the anatomy of the palm is fundamentally the same as in the sixth edition. A radial bursa connected with the flexor pollicis longus sheath, a thenar space into which drain the flexor tendon sheath and the lumbrical canal of the index finger, an ulnar bursa into which usually drains the flexor sheath of the little finger, and separate from it a middle palmar space into which usually drain the remaining flexor sheaths and lumbrical canals. Although some students of the hand have not been in entire agreement with this arrangement of the palmar structures a recent study from the Department of Anatomy and Surgery at Western Reserve University School of Medicine has challenged the identity of a middle palmar space and demonstrated an adductor space unassociated with the tendon sheath and lumbrical canal of the index finger.

In the foreword of this work Dr T Wingate Todd writes "To both Dr Brickel and myself it is a matter of deepest dismay that at the very moment when we should have wished to consult with Dr Kanavel on this important work Fate intervened and left us to carry on without his constructive criticism and approval."

Dr Kanavel's monograph is a classic work on hand infections and since its first appearance in 1912 has doubtless contributed more than any other to the intelligent treatment of this heretofore sadly neglected field of surgery.

#### *Surgical Treatment of Hand and Forearm Infections*

A C J Brickel 300 pp St. Louis C V Mosby Co., 1939 \$7.50

This carefully prepared monograph comes from the Department of Anatomy and Surgery of Western Reserve University. The foreword by T Wingate Todd should be read.

The work may be divided into two parts, anatomical and clinical. The clinical considerations concern chiefly the regional surgery of the usual pyogenic infections. To these are added the management of specific infections and human bites, the influence of diabetes and peripheral vascular disease, and the medicolegal aspects of hand injuries.

The anatomical text consists of descriptions of 14 excellent plates (10 in color). The clinical significance of the structural arrangement is epitomized in notes at the end of each description. The usual and occasional extent and relations of bursas and spaces are further set forth in the description of 17 plates and a diagram of roentgenograms

of radiopaque injections. The whole is beautifully done. The generally accepted concept of a thenar space, into which projects the flexor tendon sheath of the index finger, separated from a mid palmar space by a septum along the third metacarpal, is not confirmed by Brickel's findings. His studies show that the proximal portion of the palmar cavity is a common space which is usually filled by the ulnar bursa and its enclosed tendons and that it is continuous with a distal portion which is divided into compartments by septums separating the lumbrical canals and the tendon sheaths. Each lumbrical canal is connected distally with a web space but proximally with the common synovial cavity. The radial and ulnar bursas are usually separated, but in some hands there is a communication between them. This may be valve like in character, thus preventing the spread of pus from one to the other, but on decompression by drainage of the infected bursa the effectiveness of this barrier may be lost. The term, thenar space, is discarded for the more descriptive term, adductor space, anterior and posterior.

Although the author emphasizes the necessity of making lateral drainage incisions in the fingers dorsal to the digital vessels and although he quite properly insists that drainage material must not press against the tendons or pass beneath them, he unfortunately does not describe the intimate blood supply of the tendons themselves. Mesotenons are neither mentioned nor illustrated. Although it is stated that the use of 70 or 80 gr of sulfanilamide in divided doses each day for four days has been found of great benefit in cases of streptococcal and staphylococcal infections as an adjunct to surgery and although caution against individual susceptibility and the coincident employment of external or internal sulfates is advised, no detailed information concerning the scientific control of its administration is given.

This monograph is a valuable contribution to the subject. To a student of the hand it is fascinating. Certain anatomical features which it presents should stimulate further investigation of this economically important member of the body. The book should be carefully studied by all general surgeons and practitioners who undertake the treatment of hand infections.

*Immunity Principles and application in medicine and public health* Hans Zinsser, John F Enders and LeRoy D Fothergill Fifth edition 801 pp New York The Macmillan Co, 1939 \$6.50

The present edition enlarges the scope of the usefulness of this book. It has been written to reach a much larger group of readers than the former editions, and by the elimination of much of the older material and by the detailed discussion in Section II of the application of immunological knowledge to medicine and public health, it has become a volume which might well be placed in the library of every physician.

In Section I the authors discuss the general principles of immunology in such chapters as "Infection and Virulence," "Toxin-Antitoxin Reactions," "The Basis of Immunity," "Iso-antibodies and the Blood Groups," "Hypersensitiveness," and so forth.

In Section II the immunological problems in individual infections are discussed. Among these are chapters on virus diseases, diphtheria, scarlet fever, other hemolytic streptococcal infections, staphylococcal infections, pneumonia, whooping cough, syphilis and tuberculosis.

The writers thorough understanding of the subject and gift at expressing this knowledge make the mental transference of this information to the reader an exhilarating experience.
